This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

CHARLESTON, the largest city in the state of South Carolina, is situated in the county of Charleston, upon a narrow tongue of land formed by the confluence of the rivers Ashley and Cooper, in 32° 47′ N. lat. and 79° 48′ W. long. The harbour, which is spacious and convenient, is formed by the æstuary of the two rivers, and protected from the Atlantic by Sullivan's Island on the N. and Folly Island on the S. The entrance, which is between these islands, is obstructed by a range of sand-banks, which make three channels by which vessels of considerable burthen may enter the port, but the passage is rendered so difficult and uncertain by the tides and the shifting of the sands, that it is customary for all vessels, including even constant traders to the port, to be taken in by licensed pilots.

Charleston was founded in 1680, seventeen years after the granting of the colony by Charles II. to the Earl of Clarendon. For rather more than a century it was the capital of the province, Columbia, now the seat of government, not having been founded until 1787. The town is regularly laid out in parallel streets extending between the two rivers and crossed by other streets at right angles. The houses are for the most part spacious and lofty, and furnished with balconies and verandahs, in order to protect the interior from the sun. The streets are generally narrow and unpaved, and the soil being sandy, considerable annoyance is experienced in windy weather from dust and sand. To shelter the passengers from the sun, rows of a tree called the 'pride of India' are planted on each side of the streets; this tree does not grow to any considerable height, but its branches are spreading and its foliage thick, and it possesses the further advantage of not harbouring insects.

The town contains a city-hall, exchange, custom-house, guard-houses, theatre, orphan-house, hospital, alms-house, two arsenals, two markets, a college, and nineteen places of public worship. The yellow fever has made frequent ravages in Charleston, but its effects have been chiefly confined to strangers, and especially those from more northern climates. The place is not considered unhealthy by natives.

The population of the city, in 1790, was 16,359, of whom 7684 were slaves. In the next forty years the number of inhabitants has nearly doubled, as appears from the following statement:

	Free Whites. Males.	Free Whites. Females.	Free Persons of Colour.	Slaves.	Total
1800	..	..	..	..	18,712
1810	5863	5705	1472	11,671	24,711
1820	5809	5330	1475	12,652	25,356
1830	6326	6502	2107	15,354	30,289

These numbers do not include the population of the suburbs, which in 1830 amounted to 10,054.

Charleston is a place of very considerable trade. A great part of the cotton and nearly all the rice exported from the state are shipped from this port. The amount of registered and licensed tonnage belonging to the port in 1835 was 13,759 tons, of which 7559 tons were employed in the coasting trade. The tonnage of steam-vessels in the same year was 1889. In the year ended 30th September, 1835, the vessels that entered and left the port in the prosecution of foreign trade were—

——	Inwards.		Outwards.	
	Ships.	Tons.	Ships.	Tons.
American	115	22,460	186	48,703
Foreign	127	30,938	133	33,476
Total	242	53,404	319	82,179

The trade of Charleston in the two principal articles of export during the last seven years has been as follows—the season for shipping cotton and rice is considered to begin on the 1st of October, and to end on the 1st of April following

Years.	Arrivals.			Exports.			Stocks on hand.		
	Cotton.			Cotton.			Cotton.		
	Sea Island.	Upland.	Rice.	Sea Island.	Upland.	Rice.	Sea Island.	Upland.	Rice.
	Bales.	Bales.	Tierces.	Bales.	Bales.	Tierces.	Bales.	Bales.	Tierces.
1829-30	11,538	149,250	89,356	6,651	119,209	76,503	6,784	32,473	11,280
1830-31	11,420	118,054	81,333	9,042	89,415	63,509	7,082	30,843	13,888
1831-32	14,922	139,020	98,383	11,548	115,369	82,805	4,277	31,279	11,751
1832-33	17,914	133,327	99,689	16,280	119,430	85,102	2,124	16,424	12,946
1833-34	12,500	138,382	88,605	8,639	121,314	75,422	4,329	20,964	11,776
1834-35	11,373	135,482	89,328	7,925	121,899	82,571	4,663	16,174	5,400
1835-36	10,958	163,639	94,000	8,144	156,837	83,013	3,098	11,284	9,003

The exports of the two shipping seasons ending April 1, 1835, and 1836, were distributed as follows:

Countries and Ports.	From October 1, 1834, to April 1, 1835.			From October 1, 1835, to April 1, 1836.		
	Cotton.			Cotton.		
	Sea Island.	Upland.	Rice.	Sea Island.	Upland.	Rice.

Total	7,925	121,899	82,571	8,144	156,839	83,013

The Ashley and Cooper rivers are not navigable to any considerable distance from their mouths. To remedy this disadvantage a canal has been cut connecting the Cooper with the Santee river. The internal communication has been greatly improved by means of a railroad from Charleston to Hamburg on the Savannah, opposite to Augusta, a distance of 136 miles. This railroad was opened in 1834, and has proved very successful.

The Charleston college was chartered in 1785, but until 1824 it could be considered only as a grammar-school. In that year some alterations were made in its plans and government by means of which it was placed on a respectable footing as a college. At that time its funds had become very low, but it has since received 22,500 dollars by gift from two individuals, and its income from students has also since 1824 amounted to 10,000 dollars annually. The number of students in 1833 was 177, of whom 46 attended the scientific department, 76 the classical department, and 55 the English department. The college building is commodious: it possesses a good philosophical apparatus, and a library of 3000 volumes, besides several hundred volumes belonging to the students. The medical college, which was established in 1824, is empowered to confer medical degrees. The locality is a handsome building, for which the city council of Charleston appropriated 15,000 dollars, and the establishment has been further assisted by the states' legislature, which has granted to its funds the sum of 17,000 dollars.

Printing was introduced into South Carolina at Charleston in 1730, and the first newspaper was published in January, 1732; there were in 1834 three daily and three weekly papers published in the city. There are five banks established in Charleston with capitals amounting in the aggregate to 4,600,000 dollars; and two insurance companies, with capitals of 300,000 and 450,000 dollars respectively.

CHARLESTOWN, the principal town in Middlesex county, Massachusetts, is situated on a peninsula, formed by the river Mystic on the East, and Charles river on the West, by which latter it is separated from Boston, of which it may be said to form a suburb. The settlement at Charlestown somewhat preceded the founding of Boston. In the year 1628, Mr. Endicot, one of the patentees to whom King James the First had eight years before granted an extensive territory in America, went to New England, with about a hundred followers, and settled at the spot now called Salem. In the following year this small colony was joined by about two hundred other persons from England; but, in the course of the year, about 100 of the colonists removed, and with the consent of Mr. Endicot, settled themselves at Charlestown, then called by its Indian name of Mishawum.

In the early part of the American Revolutionary war Charlestown was destroyed by the English troops; previously to that time it was a thriving place, in which many branches of manufacture were carried on. It was speedily rebuilt, and became much more considerable than before the war. The population in 1830 amounted to 8787 souls. Besides the Charles-river bridge, by which the town is connected with Boston, there is a bridge across the river Mystic, which connects Charlestown with the town of Malden, in the same county. [BOSTON.]

CHARLEVILLE, a town in the department of Ardennes in France, in the immediate vicinity of Mézières, the capital of the department, and on the left bank of the Meuse, about 145 miles from Paris through Soissons, Reims, and Rethel. This town is of modern origin, having been built in 1609 by Charles de Gonzague, Duke of Nevers, afterwards Duke of Mantua. It is very regularly laid out, and the streets are very straight; there are four principal ones, into which the others run. The houses are of uniform height, covered with slate. There is a handsome square, surrounded by a piazza, and with a fountain in the middle. The town possesses a theatre, a considerable public library, and a museum of natural history and antiquities. Charleville was originally fortified, and had a citadel called Mont Olympe; but these fortifications were destroyed about 1687, by order of Louis XIV. of France, into whose hands the town had come. A stone bridge unites this town with the neighbouring town of Mézières.

The population of Charleville, in 1832, was 7400 for the town itself, or 7773 for the whole commune. The inhabitants manufacture iron wares, especially nails and fire-arms, of which last there is a government manufacture. Brass founding and the manufacture of soap are also carried on. There is a commodious port on the Meuse, and considerable business is transacted.

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE, born at St. Quentin in 1682, was educated by the Jesuits, and was admitted into their order in early life. In 1720 he was appointed to one of the Jesuit missions in Canada, and, embarking at Rochelle, he arrived at Quebec in the autumn of that year. He explored a large part of Canada, and examined several of the rivers and lakes, which were then not much visited by Europeans. In going from North America to St. Domingo, he suffered shipwreck; but a second voyage was more fortunate, and he reached that island in September, 1722. After two or three weeks' stay in St. Domingo, he sailed for France, and arrived at Hâvre in the month of December. He afterwards made a journey into Italy on some business of his order, which frequently entrusted him with important employments. Besides producing the voluminous works that bear his name, he wrote during twenty-two years in the 'Mémoires de Trevoux,' a literary journal conducted by the Jesuits. He died at La Flèche in 1761.

He was a laborious compiler, and the documents and accounts of foreign countries (furnished by Jesuit missionaries, who were scattered in almost every corner of the world) upon which he principally worked, were numerous and occasionally valuable; but both he and his authorities were partial, prejudiced, credulous, and superstitious, and too much given to tedious details of the proceedings and ceremonies of their own order. To this we must add that Charlevoix's style is somewhat heavy and diffuse. His separate works are, 1. 'History and Description of Japan,' which is taken almost entirely from Kämpfer; 2. 'History of St. Domingo,' which is derived from a MS. sent him by Father Le Pers, who lived twenty-five years in that island, and from some documents which existed in the bureaux of the French ministry of Marine; 3. 'History of New France,' which contains a good account of all the French establishments in Canada and North America, together with a tedious confused journal of his own travels in that part of the world; (the latter portion was translated into English in 1760, under the title of 'Journal of a Voyage to North America;') 4. 'History of Paraguay,' which was translated into English in 1769.

His thick quartos are a compound of travels and history, not very skilfully mixed; but although Charlevoix had neither the order and philosophy necessary to an historian, nor the enterprise and vivacity of a traveller, he was a very industrious man, and collected many things which still render his books valuable for occasional reference.

CHARLOCK, the vulgar name of Sinapis nigra and alba, common annual weeds which infest corn-land. They are so easily destroyed by a little care, that their presence can only be looked upon as evidence of slovenly agriculture.

CHARLOTTENBURG, a small town about a mile from Berlin, is built on the river Spree, and united to the capital by an excellent road, which is lighted by lamps. It contains a royal palace with a fine park, in which there is the sepulchral monument of Queen Luise, who died in 1810. There are also statues of the Great Elector and King Frederic I. Charlottenburg is a great place of resort for the people of Berlin, some of whom have fine country houses here. The population is about 6100. There are a few manufactures of cotton goods on a small scale.

CHARLOTTESVILLE, a post-town, and the county-town of the county of Albemarle, in the State of Virginia, on the bank of the Rivanna, a branch of the James river, It is situated in a beautiful and healthy country, about twenty miles from the Blue Ridge. Monticello, the former residence of Mr. Jefferson, is on the summit of a hill, about two miles from Charlottesville. Mr. Jefferson is buried in the grounds near the house. During the revolutionary war, Colonel Tarleton made an attempt, in which he nearly succeeded, to surprise the Virginia legislature, then sitting at Charlottesville. Mr. Jefferson, who was then governor of Virginia, narrowly escaped being taken in his own house.

The university of Virginia, which is about one mile from Charlottesville, was founded by the legislature of Virginia, under the superintendence of Mr. Jefferson, who was appointed the first rector and one of the visitors. The regulations for the government of this institution, and the general course of instruction, were formed by Mr. Jefferson. It is one of the few colleges in the United States which has not a clergyman for its president: no theological or religious instruction is given by the university.

The branches of instruction are the Greek, Latin, and Hebrew languages, the most important modern languages, mathematics, natural philosophy, moral philosophy and political economy, law, and chemistry. There is also a small medical school. The university possesses a well-selected library of about 10,000 volumes, a philosophical and chemical apparatus, an anatomical and general museum, a cabinet of minerals, and an observatory.

CHAROLLES, a town in France, in the department of Saône and Loire. [Saône et Loire.]

CHAROLLOIS, or CHAROLOIS, a district deriving its name from the above town, which was the capital of it. Charollois was a subdivision of the duchy of Bourgogne, and Philippe le Bon and Charles le Téméraire, the two last of the great feudal dukes, took, during their father's lifetime, their title from this district, being known as counts of Charollois. It is included in the department of Saône et Loire, except a small part west of the Loire, which is for the most part comprehended in the department of Allier. [Allier, Saône et Loire.[

CHAROLLOIS, CANAL DU, otherwise called the CANAL DU CENTRE, one of the most important canals in France. It was commenced A.D. 1783 and finished A.D. 1792, and runs through the district from which it takes its name, connecting the navigation of the Loire at Digoin with that of the Saône at Châlons. From its junction with the Loire it follows the valley of the Arroux, a feeder of the Loire, for a very short distance, and then that of the Bourbince, a feeder of the Arroux. The only town of any importance near the canal, in this part of its course, is Paray (population, 2722, town; 3400, whole commune). The canal then passes through the étang or pool of Long Pendu, and follows the valley of the Dheune, a feeder of the Saône, to near the town of Chagny (population 2989), and then, turning off to the right, opens into the Saône at Châlons. Its whole length is given in the table subjoined to Malte Brun's *Géog. Universelle*, at 116,812 *mètres*, or about 72 English miles. It is the seventh of the French canals in respect of length. Its length, as measured on the maps of France by A. H. Brué, and by the Society for the Diffusion of Useful Knowledge, is, as near as can be, 70 miles.

CHARON, a native of Lampsacus, on the Hellespont, one of those numerous Greek historical writers now only known by their names and a few fragments. Charon lived before Herodotus, who was born B.C. 484, and he was younger than Hecatæus, who was probably in the vigour of his life about B.C. 500. Charon wrote a history of his native town, a history of Persia, a history of Crete, and other works. The loss of the Cretan history is to be regretted, as we possess so few materials for the antient state of that island. (See Suidas, Χάρων; Creuzer, *Historicorum Græcorum Antiquiss. Fragmenta, &c.* Heidelberg, 1806, 8vo.)

Suidas mentions two other writers of the name; one of Carthage, and the other of Naucratis, in Egypt.

CHARON, the fabulous boatman who conveyed the shades of the departed across the rivers which girt the infernal regions. (Eurip. *Alcest.* 253, 441; Aristoph. *Ran.* 202; Virgil, *Æneis*, v. 298.) His fare was an obol (the sixth part of a drachme), which was laid in the mouth of a person about to be buried, in order that he might have wherewith to pay the freight. (*ναῦλον, δανάκη.* Aristoph.; J. Pollux, ix. 82; and Juvenal, iii. 267.) Charon does not appear in Homer; his origin is referred to Ægypt (Diodor. i. 90), where he had a representative in Amenthes, the emblem of a future state: his name is thought to point to the joy produced by a freedom from sublunary troubles. (See Creuzer, *Symbolik*, i., p. 341.)

CHART, or SEA-CHART, a hydrographical map, or a projection of some part of the sea, in plano, for the use of navigation. Fournier, in his *Hydrographie*, (fol. par. 1667, p. 505,) ascribes the invention of charts to Henry, son of John, king of Portugal: certain it is that marine charts appear first to have issued from the Portuguese. Bagford says, the first step that was made toward a knowledge of our own coasts was by an almanac, with a chart of the coasting part of England, printed on vellum or parchment, by Wynken de Worde, 1520, and bound in a small portable volume. This was the first he had seen of the kind. (See Bagford's *Letter to Hearne*, prefixed to Leland's *Itinerary*, vol. i., p. lxxx., and *Spicileg. ad Gul. Neubrig.*, p. 749.) John Rotz, a native of Dieppe, and servant to King Henry VIII., made for the king's use a Book of Hydrography, so called, being an account of the compass, elevation of the pole, latitude, sea coasts, &c., 1542, finely painted on eighteen very large skins of parchment, still preserved among the royal manuscripts in the British Museum, marked 20 E., ix. Of this description also is a very curious chart, preserved in the same collection, formerly belonging to Lord Oxford, and probably of as early if not an earlier date than Rotz's charts. New Holland is laid down upon it as an island, under the name of Java le Grand. The writer of the present article, many years ago, consulted the late Captain Flinders for his opinion whether this portion of the chart could have been laid down from actual observation. The answer was, 'most certainly; for lines of red dots are made to border the coast exactly to the extent to which it is coral-bound, and no farther; I was wrecked upon one of those reefs, and have reason to remember them.' The names of places are occasionally given upon the different shores in this chart, in French; and the very spot upon it which Captain Cook afterwards named Botany Bay is designated as *Côte des Herbages.*

The generality of the early Portuguese charts seem to have been made toward the close of the fifteenth century.

The particular species of charts most used at sea will be explained under the head Mercator's Projection. See also Map, and Stereographic, Orthographic, Gnomonic, and Conical Projections, under which last head look for Flamsteed's and the modern French projections.

CHARTA, MAGNA. [Magna Charta.]

CHARTE, from charta, 'paper,' was the name given to the letters of franchise granted by the kings of France during the middle ages to several towns and communities, by which they were put in possession of certain municipal rights or privileges, such as the free election of their local magistrates, &c. At present the word charte is used in France to signify the solemn acknowledgment made by Louis XVIII. on his restoration in 1814 of the rights of the nation, which is the fundamental law of the French constitutional monarchy, and the principle of which resembles that of the English constitution as founded on Magna Charta and the Bill of Rights. The legislative power is vested in two chambers, peers and deputies, subject to the king's sanction. All laws are promulgated by the king. The executive power is vested solely in the king, who appoints to all the offices of the administration, both civil and military, and has the command of all the military and naval forces. He also appoints the judicial officers, who however, when once appointed, cannot be removed by him. The king makes all treaties of peace, alliance, or commerce. His person is inviolable; but the ministers are responsible. One article of the Charte, having given occasion to a false interpretation, of which the ministers of Charles X. availed themselves to issue the famous ordonnances which gave rise to the revolution of July, was altered on the accession of Louis Philippe, and it was clearly explained that 'the king issues the necessary ordonnances and regulations for the execution of the laws, without having the power in any case to suspend the course of the law or to delay its execution.' The Charte, with this and one or two more modifications of minor importance, was sworn to by Louis Philippe on the 9th of August, 1830. Since that date, a change has been made by the legislature in the constitution of the Chamber of Peers. The Peers are for life, and the peerage is not hereditary in their families.

The Charte consists of sixty-nine articles, and is inserted in the 'Almanac Royal et National,' which is published every year. [Louis XVIII.]

CHARTER, or CHARTA. The primary meaning of Charta, or Carta, is paper, or any material to write upon, as charta pergamena (parchment). It then came to signify any deed or writing, in the same manner as liber (the inner bark of a tree), from which a sort of paper was made, now signifies any description of book.

The word Charter, though formerly used as synonymous with deeds and writings (Co. Litt., 6a), is now applied only to those grants of the king which create corporations, or confer some privilege or exemption; in fact, the word has acquired the secondary meaning of privilege or immunity.

Many charters, of great antiquity, are extant. The city of London possesses two granted by William the Conqueror in 1066, and several copies of Magna Charta and the Charta de Forestâ are in good preservation. Blackstone, quoting Matthew Paris, says, that an original great charter, under seal, was sent to every county in England, and to those which had forests within them a charter of the forest also; notwithstanding which, he continues, it is surprising how few of these originals are at present extant.

CHARTER-HOUSE, London. Sir Walter de Manny, knight, a stranger born, lord of the town of Manny, in the diocese of Cambray, in the Netherlands, who for services rendered to King Edward III. was made one of the first knights of the order of the garter, in the year of the great plague, 1349, bought a piece of ground without the bar of West Smithfield, which he inclosed and had consecrated for the burial of the dead, and where, in that year alone, more than 50,000 bodies are said to have been interred. It was thereupon called the New Church-Hawe, and a chapel was built, wherein, about the year 1360, Sir Walter de Manny intended to found a college for a warden or dean, and twelve secular priests; but in the next year that design was altered, when Michael de Northburgh, bishop of London, joined with him in the building and endowing a priory in this place for double the number of Carthusian monks, which was to be called 'The Salutation of the Mother of God,' and the foundation appears to have been finished about A.D. 1370. The gross revenue of this house at its surrender to King Henry VIII., June 10, 1535, amounted to 736*l.* 2*s.* 7*d.*, its clear income to 642*l.* 0*s.* 4½*d.* per annum. Bearcroft, in his 'Historical Account,' says the site of this house was first granted June 12, 1542, to John Bridges and Thomas Hale, for their joint lives; and April 14, 1555, to Sir Edward North, who was made a baron 1st Mariæ: his son, Roger Lord North, sold it May 31, 1565, to the duke of Norfolk, for 2500*l.*, whose son, Thomas Howard, earl of Suffolk, sold it in the 9th Jac. I. to Thomas Sutton, Esq., for 13,000*l.*, who founded upon it, and largely endowed, a most magnificent hospital, consisting of a master, preacher, a head schoolmaster, and second master, with forty-four boys and eighty decayed gentlemen, who have been soldiers or merchants, besides a physician, chirurgeons, register, and other officers and servants of the house. Beside the scholars upon the foundation, whose number is now limited to forty-two, the masters are allowed to receive certain others, whose number fluctuates from one to two hundred. The Charter-House is considered one of the first schools of the metropolis. Among the eminent persons who have received their education there, may be enumerated Dr. Isaac Barrow, the mathematician; Addison; Steele; Dr. Benson, bishop of Gloucester; Sir William Blackstone; the late earl of Liverpool; and the late Rev. Dr. Charles Burney.

The Charter-House, no doubt, derives its name from a corruption of *chartreux*, a monastery of Carthusians. The persecution of certain monks of this house forms a striking feature in the history of the Reformation of the time of Hen. VIII.

(See Dugdale's *Monasticon*, new edit., vol. vi., p. 6. Tanner's *Notit. Monast.*, edit. Nasmith, *Midd.* viii., 3. Bearcroft's *Hist. Account of Thomas Sutton, Esq.*, 8vo., Lond., 1737. Carlisle's *Descr. of the Endowed Grammar Schools in Engl. and Wales*, 8vo., Lond., 1818, vol. ii., p. 2.)

CHARTRAIN, a district in France, bounded on the N.E. by the Isle de France, on the N.W. by Perche, on the S. by the Orléanois and Dunois. It formed part of the more extensive district of Beausse. [Beausse.] It takes its name immediately from its capital, Chartres, but originally from the people, Carnutes, by whom, at the time of the Roman invasion, it was peopled. This nation is mentioned by Livy as one of those which, in the time of Tarquin the elder, king of Rome, contributed their contingent to the force which crossed the Alps and inundated the north of Italy. [Celtæ.] In the time of Cæsar they extended from the Seine to the country south of the Loire. It was in the territory of this people (which Cæsar informs us was held to be the central region of Gaul), that the Druids held their great annual convention. It is not very easy to judge of the relative political and military importance of this nation: they appear to have been under the protection of the Remi ('quorum erant in clientela' is Cæsar's expression, *De Bel. Gal.*, vi. 4), and their part in the struggle against the Romans is not such as to indicate pre-eminent power or valour. They slew Tasgetius, whom Cæsar had appointed to be their chief, and allied themselves with their neighbours, the Senones, to oppose the Romans; but the vigour and activity of Cæsar, who, in his sixth campaign, B.C. 53, took the field before the usual period of the year, led them to submit without striking a blow. In the following year they were active in forming a general confederacy of the Gauls against the Romans, and offered to take the lead in the revolt. On the appointed day, therefore, under the command of Cotuatus and Conetodunus, they assembled at one of their towns, Genabum (now Orléans), and murdered all the Roman traders whom they found there. So rapidly was the news of this stroke spread, that 'what was done at Genabum at sunrise was known before the conclusion of the first watch (i.e. before 9 p. m.), in the territories of the Arverni (Auvergne), which is 160 (Roman) miles off.' Their quota of the force destined to raise the siege of Alesia was 12,000, and they probably shared in the defeat consequent on that attempt. Towards the close of that summer, or early in the following winter, between the seventh and eighth years of Cæsar's command, they attacked the Bituriges, who had submitted to Cæsar; but Cæsar, hastily leaving his winter-quarters with a part of his troops, advanced into their country and compelled them to disperse, and left part of his army to pass the rest of the winter in quarters at Genabum. In the course of the following summer they were finally reduced by Cæsar's lieutenant, Fabius. (Cæsar, *de Bel. Gal.*, lib. v.,vi., vii., viii.)

CHARTRES, a city in France, in the department of Eure et Loir, of which it is the capital. It stands on the river Eure, a feeder of the Seine, 46 miles in a straight line S.W. by W. of Paris, or 52 miles by the road through Versailles, Rambouillet, and Epernon; in 48° 26′ N. lat., and 1° 28′ E. long.

Chartres is a very antient city. Under the Roman dominion it bore the name of Autricum, but in the fourth century this name was replaced by that of the people, the Carnutes [Chartrain], whose capital it was. It does not appear to retain any relics of Roman antiquity, save the remains of some subterranean aqueducts for conveying to the town the water of some springs about four or five miles south of it, and some subterranean passages leading from the town, and extending about seven miles to the W. and W.N.W.

In the civil dissensions of the Merovingian kings, and in the ravages of the Northmen, Chartres suffered. In 858 it was pillaged and burnt by the Northmen, taken again by them under their famous leader Hastings, but given up by him on the townsmen and the bishop agreeing to pay a certain sum as a ransom. Their neglect to pay this tribute caused another siege and capture of the town. In 911 the townsmen successfully resisted the attacks of the famous Rollo, the first duke of Normandie.

In the middle ages, Chartres was the capital of a county, which was, in the tenth century, united with that of Blois and Tours. At a later date, the town was troubled by quarrels between the clergy and the townspeople or the nobility; those between the count of Chartres and the chapter of the cathedral were made up by express agreement in 1294; but they were succeeded by long disputes between the bishop and the chapter, carried on by interdicts and excommunications, the usual weapons of ecclesiastical warfare. The county of Chartres had come by purchase into the hands of the King Philippe IV. le Bel, and had been bestowed by him on his brother Charles of Valois. Upon the accession of Philippe of Valois, son of Charles, to the crown, it was reunited to the royal domains, and continued so till it was given as dowry to the daughter of Louis XII. when married to the duke of Ferrara. During this interval it was disputed by the Bourguignon and Armagnac factions, passed under the dominion of the English, and was taken from them by surprise by Dunois, bastard of Orléans, and others. The bishop, a zealous partizan of the Bourguignon and English party, was killed in the struggle on this last occasion. In the religious wars of the sixteenth century, the town was taken and retaken by the different parties; and it was here that Henry IV. was consecrated after mastering the place by force of arms. The county of Chartres, when bestowed on the duchess of Ferrara, was erected into a duchy: it subsequently came by marriage to the dukes of Nemours, by whom it was resigned to the crown. Louis XIII. bestowed it upon his brother Gaston, duke of Orléans: upon his death, Louis XIV. gave it to his own brother Philippe, duke of Orléans, from whom the duchy was inherited up to the period of the Revolution by his lineal descendants, the present royal family of France. The eldest son of the present king, Louis Philippe, bore the title of duke of Chartres up to the time of his father's accession.

The city of Chartres is situated on the brow of a hill, at the foot of which is the river Eure, which flows here in two channels, one within and the other without the antient ramparts, which yet remain, and are surrounded by a circuit of public walks. Chartres is divided into the upper and lower towns; the upper has some tolerably commodious streets, and contains the principal public edifices: the lower town is ill built and ill laid out; the streets which unite the two are so steep as to be almost inaccessible to carriages. Every thing about the place has an air of antiquity: the houses are for the most part old; many of them still have the door-way in the form of a pointed arch, with Gothic ornaments. The suburb of Bourgneuf, by which the road from Paris enters the town, is long and straggling, presenting for the most part the appearance of a mere village consisting of cottages with their gables towards the street. There are in Chartres four squares; one in the lower town, that of St. Pierre, bordered with two rows of trees, and adjacent to the antient Gothic church, from which it takes its name; two in the upper town, viz., the corn-market and the herb-market; and one, the handsomest of all, called La Place des Barricades, outside the walls. The herb-market is adorned by an obelisk, erected by the inhabitants (A.D. 1801) to the memory of their fellow townsman, General Marceau.

But the finest edifice in Chartres is the Cathedral. The first cathedral had been burnt by the Normans, A.D. 858, but it was repaired: in the 10th century it was again burnt; and a third fire, in 1020, occasioned, according to general belief, by lightning, consumed not only the Cathedral, but nearly the whole city. By the zeal of the then bishop, Fulbert, liberal contributions were obtained towards the rebuilding, and the work was commenced; the building however proceeded slowly, and it was not until 1260 that it was dedicated. Even at that period only one of the great towers was surmounted by a spire, the second spire not having been added till the 16th century.

The principal front is one hundred and fifty French feet in breadth, and is formed by two square towers and the interval between them, the towers and the intervening part of the structure being each fifty feet in breadth. The spires which surmount the towers are of different architecture and of different heights. The old spire is a pyramid of many sides, rising to the height of three hundred and forty-two French feet from the ground: the architecture is plain and heavy; but it is cased with stone curiously carved like the scales of a fish: it always appears to be leaning towards the spectator wherever he may be standing. The new spire is 378 French feet high: it is of much more florid architecture than the other, and is so much admired as to have become proverbial for its beauty. That part of the front which is between the towers has a portal with three doorways, with pointed arches, and is adorned with statues, which were preserved at the destruction of the former cathedral, and are interesting as memorials of the state of the arts in the dark ages. Above the doorways are three arched windows with stained glass, and still higher a superb circular window, or rose. The north and south sides of the church are of equal interest with the principal front. The transepts have each a handsome portal of three doorways, built out from the church; over these are windows, and over the windows a large rose.

The interior of the church is admirable for the justness of its proportions; it has a peculiarly sombre character, which arises from the windows being so charged with colour as to exclude more light than usual. It is only in very clear weather that there is light enough to read. The choir is beautiful: it is adorned with statues and bas-reliefs of various merit: the Descent from the Cross, a bas-relief by Bridan, is a chef-d'œuvre: and the Presentation of our Saviour in the Temple, by the same sculptor, is much admired. There is a noble group behind the high altar, of the Assumption of the Virgin, also by Bridan. A curious anecdote is connected with this piece. During the revolutionary troubles, the barbarians who were predominant proposed to destroy it, and were proceeding to execute their purpose, when one of those present, anxious for its preservation, proposed to crown the figure of the Virgin with the *bonnet-rouge*, and thus transform her into a goddess of liberty. The offer was accepted, and the sculpture was thus preserved. The inner dimensions of the cathedral are as follows:—length, three hundred and ninety-six feet; breadth at the transept, one hundred and ninety-five feet; height to the point of the vaulted roof, one hundred and six feet. The above dimensions are in French feet, which exceed the English feet in the proportion of 16 to 15. Under the cathedral is a subterranean church, with several chapels, one of which, the chapel of the Virgin, was formerly much resorted to by pilgrims.

Chartres had formerly seven parish churches. That of St. André (St. Andrew), which was collegiate, stood on the bank of the Eure, and having to be enlarged, a bold arch was thrown over the river, and upon this arch the choir was built. The choir has since been destroyed, and the rest of the church, used as a store-house, is falling to ruin. The church of St. Pierre (St. Peter) has some fine painted windows: this was once the church of a Benedictine abbey, now converted into a barrack. There were formerly several religious houses. The office of the Prefect is a new building, with pleasant gardens round it: and there is a handsome modern theatre.

The population of Chartres, in 1832, was 13,376 for the town, or 14,439 for the whole commune. The chief trade of the place is in corn and flour; the corn-market is the first in France. Some serges and other woollen goods are manufactured, and some hosiery; a good quantity of leather is made, and there are several dye-houses. There is a museum of natural history, and a public library of 30,000 volumes and 700 manuscripts. A noble hospital or almshouse has been lately founded by M. d'Aligre, who has devoted to its erection and endowment a sum of more than 80,000*l*. It is intended for 100 infirm persons, of each sex, and 100 foundling children.

The arrondissement of Chartres contained in 1832 a population of 103,783. (Dulaure, *Hist. des Environs de Paris*; Vaysse de Villiers; Malte-Brun.)

CHARTREUSE, a celebrated monastery of the Carthusians (*les Chartreux*) [CARTHUSIANS], the first established of that order, and therefore distinguished by the epithet *La grande Chartreuse*. It is in the department of Isère, in France, and amidst the sublime scenery of the Alps. Travellers who wish to visit it usually go from Grenoble on account of the better accommodation for the journey to be procured there, although the post town of les Echelles in Savoy is considerably nearer. However, in going from Grenoble, travellers frequently make a circuit which brings them into the road from les Echelles at the village of St. Laurent du Pont, the approach in that direction being more picturesque. From St. Laurent the road runs along the bank of a mountain-torrent, the Guier, through a narrow pass, which is closed by a house with an arched gateway under it and a double door. This doorway is the entrance to the inclosure of the Chartreuse, which is formed by a group of mountains, the loftiest, steepest, and wildest in the neighbourhood, covered from their base to their summit by a dark pine-forest. In this inclosure the road runs through a thick pine-forest, a lofty mountain rising precipitously on the right, and on the left is the abyss through which the Guier flows. After a while the valley widens, the forest is no longer so dense as to exclude the light, and the beech replaces the pine, which is seen only on the summit of the rocks; at length the forest ceases, and the traveller emerges into a large meadow, at the farther end of which the monastery appears in all its extent.

The other approach, and the more direct from Grenoble, is by a mountain, Le Sapey, from the summit of which is a fine view of Grenoble and the valley of Grésivaudan, in which it is situated. The road from Le Sapey to the inclosure of the Chartreuse lies through pine-forests with some intervals of pasture; there are even some farm-houses and a small hamlet. The inclosure of the Chartreuse is entered on this side by a narrow pass and by a house with a gateway under it, similar to that already described; and at a short distance from this entrance is the village of Chartreuse, from which the monastery derives its name.

This awful solitude was the cradle of the Carthusian order. [BRUNO.] Bruno himself did not give any rules of his own to his followers; to reduce the Carthusian discipline to a system was the work of a remote successor. The cell of St. Bruno is now converted into a chapel, and the fountain is still shown at which he quenched his thirst.

This monastery has been burned eight times; twice by the Calvinists in the religious wars of the sixteenth century.

Our authorities do not state when the present building was erected; it is a substantial edifice of simple architecture, but magnificent by its extent and situation. The buildings inclose a large oblong square or cloister, 714 English feet in length: the cells of the fathers, eighty in number, are around this cloister, with mottoes from scripture or some religious book painted outside the doors; each cell includes two rooms, besides a closet for books, and a wood-room on the ground floor, opening into a little inclosed garden. The hall is adorned with portraits of all the generals of the order; the table of the kitchen is formed of two coarse marble slabs of enormous size; there are extensive cellars, and a place where cheese is made similar to that of Gruyères.

Before the French Revolution, the monks had considerable property in the woods around the monastery, but at the Revolution they lost this as well as the monastery itself. The woods were sold, but the building, not being suited for any purpose, found no purchaser. Upon the return of the Bourbons, the monks came back and recovered the monastery, with the meadows around it, and the right of gathering fuel in the woods. In 1830 there were about 150 persons, monks and lay brethren, in the monastery: they visit the sick, and perform spiritual duties in the small churches or chapels scattered over the surrounding mountains. (Vaysse de Villiers: Expilly; *Penny Magazine*.)

CHASE, that part of a gun which is between the ring near the trunnions, and the astragal mouldings near the muzzle.

CHASMO'DIA, a genus of coleopterous insects of the section *Lamellicornes* (*Scarabæus*, Lin.), and sub-section *Xylophili* (Latreille). Technical characters:—Body rather convex and broad: scutellum large, somewhat triangular, equalling in length at least one third of that of the elytra: the mesosternum is prolonged into a blunt point, and extends as far as the base of the femora of the anterior pair of legs: the mandibles are entire, and obtuse at the apex: maxillæ with only two teeth, and furnished with a tuft of fine hairs at the extremity; mentum elongated: elytra shorter than the abdomen, broad behind and obtusely rounded. The male Chasmodia has the upper claw of the fore tarsi very broad and bifid, or divided at the apex: the inner claw is small and entire; the claws of the four posterior legs are entire and of large size. The female has all the claws of small size; those of the anterior pair of legs simple; the four posterior legs have the outer claw bifid*. The tarsi of the male are thicker than in the female, particularly those of the anterior pair of legs.

All the species of this genus are of large size, and may be readily distinguished from the Cetoniæ by their large scutellum and convex form, combined with their smooth and glossy appearance. The thorax is convex, and has the posterior margin considerably waved; the part joining the scutellum has a segment of a circle as it were cut out to admit the fore part of the latter, which is rounded: this character is also observed in the genus Cetonia and Macraspis, and affords a good point of distinction between these and the groups nearest allied. The genus Macraspis has also a very large scutellum, but differs in the tarsi and other parts, which will be described under the proper head.

Chasmodia viridis is about an inch in length and of a deep blue-green colour throughout, with the exception of the antennæ, the basal joints of which are pitchy red, and the club is black.

There are four other species known, some of which are of a glossy brown or chestnut colour; they all inhabit South America: the species above named is common in collections from the Brazils. [MACRASPIS.]

CHASTELLET, GABRIELLE-EMILIE LE TONNELIER DE BRETEUIL, MARQUISE DU, the translator of Newton into French, was the daughter of Baron de Breteuil, and was born in 1706. In what manner she was led to study mathematics is not stated; she also became a proficient in Latin, English (in which Voltaire, as he tells us, was her instructor), and Italian. She was married very early to the Marquis du Chastellet, and died August 10, 1749, her death having been hastened by close application to her translation of Newton. She died in the palace of Luneville, at the court of Stanislas, where Voltaire also was then residing. Her *liaison* (as the French call it) with Voltaire furnished sundry anecdotes for the scandalous chronicles of her day. The state of manners however, and in particular the method in which marriage was contracted among the French, are too well known to require any comment.

In 1738 Madame du Chastellet wrote, for the prize of the Academy of Sciences, on the nature of fire. In 1740 she published at Paris her 'Institutions de Physique,' addressed to her son, and a second edition appeared at Amsterdam in 1742. This work is a series of letters, in which the systems of Leibnitz and of Newton (the latter then almost new in France) are explained in a familiar style, and with a degree of knowledge of the history of the several opinions, and of sound language and ideas in their discussion, which we read with surprise, remembering that they were the production of a Frenchwoman thirty years of age, written very few years after the introduction of the Newtonian philosophy into France. She takes that intermediate view between the refusal to admit the hypothesis of attraction, and the assertion of it as a primary quality of matter, from which very few who consider the subject would now dissent. At the end of this work is an epistolary discussion with M. de Mairan, on the principle of *vis viva*, the metaphysical part of which then created much controversy.

The translation of Newton was published at Paris in 1759, with a 'préface historique,' and an *éloge* in verse by Voltaire, who probably owed to Madame du Chastellet the smattering of knowledge upon which he wrote his 'Elémens de la Philosophie de Newton,' published in 1738. From it we learn that the translation was submitted to the revision of Clairaut, who was the instructor of the authoress in mathematics. To the work is added a commentary, which bears the name of Clairaut, being in fact his lessons committed to writing and arranged by Madame du Chastellet, and afterwards revised by their author. We here find, 1. a popular account of Newton's system; 2. investigations of various points by the analysis of the continental school, to the exclusion of the geometry of Newton; 3. an abridgment of Clairaut's work on the figure of the earth; 4. another of Daniel Bernoulli's essay on the tides. The translation itself is a close copy of the original in form and matter, but does not profess to be perfectly literal, where the Latin is concise or obscure. It was used by Delambre in his citations (*Hist. d'Astron.*, xviii. siècle), expressly that he might have the sanction of Clairaut in his versions of Newton. In 1806 the correspondence of Madame du Chastellet with the Count d'Argental was published at Paris, to which was appended a life, and a treatise 'Sur le Bonheur.' (*Biog. Univ.*; *Mémoires pour servir à la Vie de Voltaire, écrits par lui-même*; *la Vie de Voltaire, par* Condorcet.)

CHATEAUBRIAND. [LOIRE INFERIEURE.]

CHATEAU CHINON. [NIEVRE.]

CHATEAUDUN, a town in France, in the department of Eure et Loir, on the banks of the river Loir (which uniting with the Sarthe flows into the Loire), and on the road from Paris to Tours. It is 68 miles in a straight line S.W. of Paris, or 81 miles by the road through Rambouillet and Chartres, and 29 miles S. by W. from the latter town, which is the capital of the department: 48° 5′ N. lat., and 1° 18′ E. long.

This town was formerly the capital of the Dunois, a district included in the general government of Orléans, and in the diocese of Chartres. It is a town of considerable antiquity, being mentioned by Aimoin and Grégoire of Tours. In the tenth century it appears to have been subject to Thibaut le Tricheur, Count of Blois, Tours and Chartres, who built here an old tower, part of the castle, which is still standing. Afterwards Châteaudun had viscounts of its own until the fifteenth century, when it was united with the county of Dunois. The counts of Dunois built the rest of the castle.

Châteaudun was burnt in 1723, and rebuilt on a regular plan, which renders it one of the handsomest towns in France. The streets are broad and straight, with neat and uniformly built houses, and some good public buildings, such as the town-hall, the office of the sub-prefect, formerly a convent, and the college or high school. The castle is a Gothic building, and one of the finest of the kind in France. The walls of the old tower, built by Thibaut, are about 16 feet thick. There is a good *place*, or square, and a handsome public walk.

The inhabitants, in 1832, amounted to 6461. They do not seem to be engaged to any great extent in trade or manufactures except that of blankets. There is a public library.

Châteaudun was erected into the capital of a bishopric in the sixth century, by one of the Frankish Merovingian princes; but the act having been irregular, the pretended bishop could not maintain his station. It is now the capital of an arrondissement, which had, in 1832, 52,752 inhabitants.

CHATEAU GONTHIER, a town in France, in the department of Mayenne, on the right bank of the Mayenne, and on the road from Laval to Angers. It is about 154 miles W.S.W. of Paris, in 47° 50′ N. lat., and 0° 41′ W. long.

This town was built by Foulques, or Fulk Nerra, count of

---

* We have been more than usually minute in these characters, because in two works referred to they are wrongly described. In the 'Règne Animal' the claws are described as being entire.

Anjou, about A.D. 1037. It would be a handsome town if its streets were not so crooked. The houses have a cheerful aspect, and several of them are handsome.

There is a pleasant promenade commanding a delightful prospect of the country through which the Mayenne flows; the banks of the river are adorned with pleasant meadows, orchards, and walnut-trees, and crowned with steep slopes. One of the principal suburbs is separated from the town itself by the river.

The inhabitants amounted, in 1832, to 6143. The chief branches of trade are in linen cloth, of superior quality, which is made and bleached here, and in wax: serges, and other woollens, hats, and leather, are also made, and the town serves as an emporium for the wine, coal and slate of Anjou. There is a good High School, and three hospitals, or almshouses. The arrondissement of Château Gonthier had, in 1832, a population of 72,888: it is the chief grain district of the department.

CHATEAULIN. [FINISTERRE.]

CHATEAUROUX, a town in France, capital of the department of Indre, on the river Indre, and on the road from Paris by Orléans to Limoges, 144 miles S. by W. from Paris, in a direct line, or 157 miles by the road; in 46° 48′ N. lat., and 1° 40′ E. longitude.

The town takes its name from a Frankish noble, Raoul de Déols, who built both the town and castle: Châteauroux is therefore a corruption of Château Raoul. Its feudal history has neither importance nor interest. The town is situated in an extensive plain, in which a great number of cattle are fed. The castle stands at one end of the town, on a hill, and notwithstanding its great antiquity, still serves as the office of the prefect. Mr. J. Cobbett describes the town as 'a confined and dirty assemblage of streets and houses, on a rapid declivity, under which runs the Indre.' There is an antient church in the lower town almost destroyed, and a prison, consisting of two towers and an archway, formerly, no doubt, one of the gates of the town, though from the continued increase of the place it is now nearly in the middle of the town. (*Letters from France.*)

The population, in 1832, was 10,851 for the town, or 11,587 for the whole commune. The principal manufacture carried on is that of woollen cloth. There is a library, a Society of Agriculture, Commerce, and the Arts, a college or high school, and a theatre. The population of the arrondissement, in 1832, was 90,545.

CHATEAU THIERRY, a town in France, in the department of Aisne, on the bank of the river Marne, and on the road from Paris to Bar, Nancy, and Strasbourg. It is 47 miles E. by N. of Paris in a straight line, or 56 miles by the road: 49° 2′ N. lat., and 3° 21′ E. longitude.

The town derives its name from a castle built about A.D. 720, by Charles Martel, as a residence for Thierry IV., a child whom he had made nominal king. Round this castle a town was gradually formed, which became at a later period the residence of the counts of Champagne.

Château Thierry rises in the form of an amphitheatre on the right bank of the river. It is well built, and is overlooked by the ruins of an antient castle. The population, in 1832, was 3749 for the town, or 4697 for the whole commune. The chief articles of manufacture are linens, cottons, earthenware, and leather. Considerable trade is carried on in corn, wool, cattle, wine, gypsum, and mill-stones.

This town suffered severely in the invasion of France by the allies, in 1814: the town and suburbs were three times pillaged. It is the native place of La Fontaine, whose statue has been erected upon the bridge over the Marne. Château Thierry is the capital of an arrondissement, which had, in 1832, 60,771 inhabitants.

CHATELET, or **CHASTELET**, properly a little fortress. This name was afterwards given to certain courts of justice, formerly established in several cities of France, as at Orléans, Montpellier. &c. The Grand Châtelet, at Paris, was the place where the presidial and ordinary court of justice of the provost of Paris was held. It consisted of a presidial, a civil chamber, and a chamber of policy. The Little Châtelet, at Paris, answered to its proper name; it was an antient fort, serving as a prison. (See Furetière, *Diction. Universel, in voce.*)

CHATELLERAULT, a town in France, in the department of Vienne, on the river Vienne, and on the high road from Paris to Bordeaux. It is 164 miles S.W. by S. from Paris in a straight line, or 190 miles by the road: in 46° 50′ N. lat., 0° 32′ E. long.

This town owes its origin and name to Hérault, lord of the soil in the eleventh century, who built here a castle, Château d'Hérault, which is no longer in existence. The town stands on the right or east bank of the Vienne, which separates it from one of its faubourgs or suburbs. This suburb is united to the town by a fine stone bridge, built by the celebrated duke of Sully, the approach to which on the town side is by an avenue forming a public walk, and by a gateway passing through a castle with four towers, also built by Sully. Some have confounded this with the old Château d'Hérault, which, as observed above, has been demolished. The town itself is ill built, but has been improved during the present century by several new houses, the result of the increasing trade of the town.

The inhabitants amounted, in 1832, to 9437. They were formerly engaged in the manufacture of clocks and watches and cutlery. The manufacture of clocks and watches is not, however, mentioned by the more modern of our authorities; that of cutlery still continues to be the staple article of the town. Five hundred families are said to be engaged in this branch of industry, but they are supported rather than enriched by it. Their knives are particularly in repute; they are cheaply and nicely got up, but their temper wants hardness: they are stamped by appointed officers, who are particular in rejecting such as are not properly finished. The sale of these articles to passengers through the town is considerable, and M. Millin (*Voyage dans les Départements du Midi*, Paris, 1811,) gives the following account of the eagerness with which the dealers press the sale of their articles. 'As soon as the traveller reaches Châtellerault, he is assailed by a swarm of women, whose object is to urge by every means the sale of their knives. However he may entrench himself in his carriage, there is no means of escape; they immediately hang on the doors or clamber up the naves and spokes of the wheels, or get upon chairs: the mind anticipates with alarm the accidents which might happen if the horses were to start; and the traveller, apprehensive of causing some disaster, opens the window, and is immediately beset with more urgent entreaties. Harassed and worried, he at last makes a purchase; and then the roguish postilion, who was in league with these clamorous petitioners, whips on his horses; but up to the purchase he always finds something to do, or some part of his harness that wants to be adjusted.' The manufacture of serges and other woollen stuffs, *sabots* or wooden shoes, leather, and lace, is carried on; and there are three places for bleaching wax. To the above articles of trade may be added wine, grain, wool, hemp, fruits, wax, honey, nut oil, and other agricultural produce, and millstones. The trade of the place is much favoured by its situation on the river Vienne, the navigation of which commences about seven miles above the town, and on which there is a good port. During the last war, when the maritime superiority of England interrupted the coasting trade of France, Châtellerault became the centre of considerable internal trade. The wines and brandies of the south were brought hither by land, and transmitted to the north of France by the Vienne, the Loire, the Canal d'Orléans, and the Seine; while the linens and woollens of the north, arriving at Châtellerault by water-carriage, were dispatched by land to Bordeaux.

Châtellerault is the capital of an arrondissement, which contained, in 1832, 50,413 inhabitants. It contains a high school, an agricultural society, and a theatre. It was the native place of Jean Daillé, a celebrated Protestant minister and writer. The Scotch duke of Hamilton bears the title of duke of Châtellerault, which was bestowed on one of his ancestors in 1548.

CHATHAM, a market-town and parliamentary borough on the Medway, in the lathe of Aylesford, Kent. The town (including Brompton, which is a village connected with the dock-yard and naval and military establishments, at a little distance from what is strictly the town of Chatham) is in the two parishes of Chatham and Gillingham, and joins Rochester on the east. Its distance from London by the Dover road, which varies but little from the direct distance, is about thirty miles E. by S. By the Reform Act, Chatham was created a parliamentary borough, with a boundary extending considerably on the S. and E. sides of the town, and it now returns one member. The population within the boundary was estimated at 19,000; the returns of 1831 give 16,485 as the population of the town.

From various discoveries made in erecting the fortifications which inclose the naval and military establishments at Chatham, it seems probable that the Romans had a burying ground here. A number of antient graves and other excavations were opened, and Roman bricks, tiles, coins, and weapons were found. The name of the town is Saxon, and was written Cetoham or Caettham, which is supposed to signify 'the village of cottages.' It continued an insignificant place until the formation of the dock-yard, since which time the town has sprung up. The parish of Chatham is very extensive; a small part of it is within the liberties of the city of Rochester. The parish church was almost entirely rebuilt in 1788; in addition to it there is a church, erected in 1821 by the commissioners for building new churches, the patronage of which is held by the incumbent. The parish is in the diocese of Rochester.

The extensive naval and military establishments are at Brompton, a little distance from the town, and entirely separated from it by a line of fortifications. The dock-yard was founded by Queen Elizabeth, previous to the invasion of the Armada, on the site of what is now termed the Ordnance Wharf, and occasionally the Old Dock. It was removed to its present situation in 1622, the demands of the navy requiring increased accommodation. Elizabeth erected Upnor Castle, on the opposite side of the Medway, for the purpose of defending the dock-yard and shipping. But this fort proved ineffectual for protection from the attempt of the Dutch, under De Ruyter, who, in 1667, having taken Sheerness, dispatched his vice-admiral, Van Ghent, with seventeen sail of light ships, and eight fire ships, to destroy Chatham. He succeeded in breaking a chain stretched across the Medway, and, in spite of the fire from the castle, burnt and sunk some ships. Finding the country alarmed, he retired, carrying off a ship of war named the Royal Charles. It appears from Pepys's *Diary*, that this attempt of the Dutch created great alarm, and that the greatest confusion and imbecility prevailed at this time in the English councils. After the affair was over, the various parties connected with the admiralty strove, with characteristic meanness, to shift the blame on others. This event was the cause of stronger and additional fortifications being erected.

In the reign of Queen Anne two acts of parliament were passed for the extension of the dock-yards and arsenals of Chatham, Portsmouth, &c. But nothing very important was effected at Chatham until after 1757, when, from that period down to 1805, according as alarm respecting French invasion prevailed, or as the rapidly increasing navy required, new buildings were erected, and the extensive area occupied by the different establishments was inclosed by a strong line of fortifications on the land side, and protected on the river side by strengthening Upnor Castle, by the erection of a martello tower called Gillingham Fort on the Chatham side, and other defences. Upnor Castle is at present merely a powder magazine.

The naval and military establishments consist of a dock-yard, nearly a mile in length, which has four wet docks capable of receiving vessels of the largest class; an extensive arsenal; barracks on a large scale for artillery and engineers, infantry and royal marines; a park of artillery; magazines and store-houses; besides a handsome dock-chapel, and a number of habitations for the civilians who are employed. The principal mast-house is 240 feet long by 120 wide. The rope-house is 1128 feet in length, and 47½ wide, in which cables 101 fathoms in length and 25 inches in circumference are made. The machinery used in all the departments is of the very best kind. A duplicate of Brunel's block-making machine is kept here, ready for use in case the machine at Portsmouth should get out of order. The engineer barracks are built in a plain and simple style, and are extensive and convenient. There is a school for engineers, which was established in 1812, in which young officers and recruits of the engineer service are trained to a practical knowledge of their duties. Near the dock-yard gate is a large naval hospital, which was erected at the suggestion of the present king (William IV.) when lord high admiral.

At Rochester Bridge, the Medway, which discharges into the same æstuary with the Thames, is a large tide river. The rise is eighteen feet at spring and twelve at neap tides at Chatham. Above Rochester the high lands approach each bank of the river, forming a kind of amphitheatre [illegible] Chatham and Rochester on the east side, and also on [illegible], closing on the river at Upnor Castle. Below Chatham dock-yards the high lands decline, first on the right, and then on the left bank forming a flat, marshy country, to the spacious outlet of the Medway at Sheerness.

There is an establishment for convicts at Chatham, consisting of four ships, one being appropriated for juvenile offenders, and another used as an hospital. The prisoners are employed in different departments of the dock-yard and arsenal.

The 'Chest' at Chatham was established in the reign of Elizabeth, and was originally a voluntary contribution from the monthly wages of seamen for the support of their maimed and superannuated brethren, but which soon settled into a compulsory payment. Several notices occur in Pepys's *Diary* of complaints of maladministration of this charity. On the recommendation of the Commissioners of Naval Inquiry, it was, by the 43 G. III. c. 119, removed to Greenwich. The monthly payment from the wages of seamen is now abolished by the 4 W. IV. c. 34, and the amount is charged annually on the consolidated fund.

An hospital for lepers was established at Chatham by bishop Gundulph, in the reign of William the Conqueror. It appears to have been incorporated. Its revenues, which were small, escaped confiscation at the time of the dissolution of the monasteries, though attempts were afterwards made in the reigns of Elizabeth and James I. to wrest them from the hospital. The building does not now exist, with the exception of a small chapel, but the revenues of the estate are in the hands of the dean of Rochester. On the north side of the High-street, or principal street of Chatham, there is an hospital for decayed mariners and shipwrights, which was founded by Sir John Hawkins in 1592, and incorporated by Elizabeth in 1594. It is a neat and convenient building: the funds support ten pensioners. There are several minor charities.

The Education Returns of 1835 give nine daily schools, and ten sunday schools as then existing at Chatham.

(Hasted's *Kent*; Douglas's *Nenia Britannica*; Pepys's *Diary*; Dupin's *Military and Naval Power of Great Britain*; *Boundary Report*; *Population Returns*.)

CHATHAM, EARL OF. [PITT.]

CHATILLON, the name of several towns in France, of which we shall only observe here that Chatillon-sur-Seine [CÔTE D'OR] was the scene of fruitless negotiations between Napoleon and the allied powers before the capitulation of Paris, 1814; and that the castle of Chatillon-sur-Loire [LOIRET] was the property of the great Coligni, hence called 'the admiral of Chatillon.'

CHATOE'SSUS, a genus of fishes of the herring family. [CLUPEIDÆ.]

CHATRE, LA, a town in the department of Indre, in France, on a cross road leading from Châteauroux to Guéret. It is 159 miles S. by W. of Paris, in 46° 35′ N. latitude, and 1° 59′ E. longitude.

This little town is situated in a pleasant country, on a gentle slope, on the left bank of the river Indre. The inhabitants, who amount to 3913 for the town, or 4343 for the whole commune, manufacture some serges, and trade in cattle, wool, and leather. It is the capital of an arrondissement, which contained in 1832 52,497 inhabitants.

CHATSWORTH, an extra-parochial liberty, in the hundred of High Peak, county of Derby, 3 miles from Bakewell, and 16 from Buxton, is the seat of the duke of Devonshire, who is constable of the Peak. The present mansion stands on the site of a former one, in which Mary, queen of Scots, passed the greater part of her long captivity in England, and which, during the civil wars, was alternately in possession of the parliamentarians and royalists, and withstood the siege of the parliamentarian troops in 1645. It was taken down at the close of that century to make room for the present beautiful structure, which was not completed until 1706. During the time that it was building, it was the residence of Marshal Tallard, the French general, who had been made a prisoner at the battle of Blenheim. The house is built in the Grecian style, with Ionic columns, with a flat roof and balustrade round it. It is about 190 feet square, inclosing a court with a fountain in the centre. The stone was hewn out of a neighbouring hill. The park is ten miles in circumference, through which, and in front of the mansion, flows the Derwent. The water-works, which are so ornamental to the pleasure grounds, are supplied from a reservoir on the summit of the nearest hill. Chatsworth is part of the duchy of Lancaster, and within the jurisdiction of a court of pleas held at

Chapel en le Frith for the recovery of debts under 40*s*; but its population is returned with the parish of Edensor

CHATTELS (Catalla). This term comprehends all property moveable or immoveable, which are not freehold. Chattels are called real, which, in the language of the earlier law writers, savour of the reality; that is, relate to or are interests in land. Chattels personal are moveable goods, as horses, plate, money, &c. Chattels of each description pass to the personal representatives of the deceased proprietor, and are comprehended under the general term 'personal property.' The laws which govern this description of property are now, from the growth of the mercantile system and the change of manners, equal in importance with those relating to realty; but during the prevalence of the feudal system, and the laws to which it more immediately gave rise, chattels (including even terms for years) were considered of small importance in a legal point of view, and, indeed, prior to the reign of Henry VI., were rarely mentioned in the law treatises and Reports of the day. (Reeve's *Hist. Eng. Law*, 369.) Many articles of property, intrinsically chattels, from their intimate connexion with other property of a freehold nature, and being necessary to its enjoyment, descend therewith to the heir, and are not treated as chattels. Thus, for instance, the muniments of title to an estate of inheritance, growing trees and grass, deer in a park, and such fixtures as cannot be removed from the freehold without injury to it, are not chattels, because they pass to the heir. In the hands of a person however who has a limited interest in such things, they become his chattels, and pass to his executor. Chattels, except so far as they may be impressed with the nature of heir-looms, cannot be entailed, though they may be limited so as to vest within 21 years after the death of a person or persons in being. They are not within the statute of Uses, inasmuch as the proprietor of a chattel is said to be *possessed* of it, not *seised*, which is the word used in that statute; nor are the same formalities required in passing a chattel by devise, as in the case of real property. A will of chattels may also be at an earlier age than one which disposes of real estate; at fourteen years of age by a male, and twelve by a female. They do not go in succession to a corporation sole, except only in the cases of the king and the chamberlain of the city of London. (Co. Litt.; Bl. *Comm.*)

CHATTERTON, THOMAS, was born at Bristol on the 20th of November, 1752. His father (who died three months before the birth of his son) was a singing master at the cathedral, and also master of a charity school in Pyle-street. At the age of five years he was placed under the care of Mr. Love, who succeeded his father as master; but his progress was so slow, that after his master had exhausted his patience in attempting to teach him, he sent him back to his mother as a 'dull boy, and incapable of further instruction.' His mother now took him under her care, and at the age of six years he first learned his letters from the illuminated capitals of an old musical MS., with which, to use her expression, he 'fell in love;' and it is probable that his passion for antiquarian pursuits received its first impulse from this circumstance. His progress was now as rapid as it had before been slow; books of all kinds, but more especially those which treated of ancient customs, were his chief companions. On the 3rd August, 1760, when not quite eight years of age, he was admitted into Colston's school, Bristol, an establishment much upon the same plan with Christ's Hospital, in London. He remained here seven years, during which time he wrote some minor pieces of poetry, chiefly satirical, and the celebrated De Bergham pedigree. On the 1st July, 1767, he left the charity school, and was bound apprentice to Mr. John Lambert, attorney, of Bristol, for seven years. While in Mr. Lambert's service he communicated to Felix Farley's Bristol Journal the article by which he first attracted attention. In the beginning of October, 1768, the new bridge at Bristol was completed, and at that time there appeared in Farley's Journal an article purporting to be the transcript of an ancient MS., entitled, 'A Description of the Fryars first passing over the Old Bridge, taken from an Antient Manuscript.' This paper, so singularly curious, and exhibiting such strong powers of invention, was traced to Chatterton, who was at first rather harshly interrogated as to the manner by which it came into his possession. After several contradictory statements, he asserted that he had received the paper in question from his father, who had found it, with many others, in some chests in Redcliff church, where they had been deposited in the muniment room, in 'Canynge's cofre.' Soon after this occurrence he became acquainted with Mr. Catcott, a gentleman fond of antiquarian researches, and with Mr. Barrett, surgeon, who was engaged in writing a history of Bristol. To the former gentleman he took, very soon after his introduction to him, some of the pretended Rowleian poems, among which were 'The Bristow Tragedy,' Rowley's Epitaph upon Mr. Canynge's Ancestor, with some other small pieces. This Rowley, according to Chatterton, was a priest of the fifteenth century, who had been patronized by Canynge. (BRISTOL, p. 432.) He shortly afterwards presented to Mr. Catcott the Yellow Roll. To Mr. Barrett he furnished an account of every church and chapel in Bristol, which he stated to have been found by him among the old parchments. The pretended originals bore all the marks of antiquity, which he had made them assume by rubbing them with ochre, stamping on them, and blacking them in the chimney, or by the flame of a candle. Mr. Barrett published these statements in his work, fully believing them to be genuine. After his introduction to these gentlemen Chatterton's ambition increased daily, and he often spoke in raptures of the undoubted success of the plans that he had formed for his future life. His pursuits were various—heraldry, English antiquities, metaphysics, mathematics, astronomy, music, and physic, by turns occupied his attention; but the two first were his favourite pursuits.

His attention, however, was not confined to the Rowley poems. He wrote various pieces, chiefly satirical; and several essays, both in prose and verse, which he forwarded to the periodicals of the day. Most of his pieces appeared in the 'Town and Country Magazine.' Growing disgusted with a profession ill suited to his tastes, and with a master whom he disliked, he made an application in March, 1769, to Mr. Horace Walpole: the ground of which was an offer to supply him with some accounts of a succession of painters who had flourished at Bristol, which Chatterton affirmed to have been lately discovered, with some old poems, in that city. Walpole accepted the offer with warmth, but afterwards seems to have cooled upon it, either from suspecting the forgery of the accounts, or ascribing but little value to them; and on being importuned by Chatterton for his assistance to release him from his profession, he neglected to answer his letters. At last, when he had received a dignified and spirited letter from Chatterton, demanding his MSS. (a letter which he termed 'singularly impertinent'), he returned the MSS. and letters in a blank cover.

Being determined to relinquish his profession, Chatterton made every effort to accomplish this object. The idea of suicide became familiar to his mind, and he often intimated to Mr. Lambert's servants that he would put an end to his existence. On hearing this the family of his master became alarmed; but Mr. Lambert himself could not be persuaded that his threats meant anything, until he found one day on his desk a paper entitled, 'The last Will and Testament of Thomas Chatterton,' in the following terms —'This is the last will and testament of me, Thomas Chatterton, of the city of Bristol, being sound in body, or it is the fault of my last surgeon; the soundness of mind the coroner and jury are to be judges of, desiring them to take notice that the most perfect masters of human nature in Bristol distinguish me by the title of the mad genius; therefore if I do a mad action it is conformable to every action of my life, which all savoured of insanity. Item. If, after my death, which will happen to-morrow night before eight o'clock, being the feast of the resurrection, the coroner and jury bring it in lunacy, I will and direct,' &c. &c. This alarmed Mr. Lambert, who considered it imprudent to keep him any longer, and accordingly he dismissed him after he had been in his service about two years and nine months.

Chatterton went up to London, having received liberal offers from the booksellers. 'My first attempt,' said he, 'shall be in the literary way: the promises I have received are sufficient to dispel doubt; but should I, contrary to my expectation, find myself deceived, I will in that case turn Methodist preacher. Credulity is as potent a deity as ever; and a new sect may easily be devised. But if that too should fail me, my last and final resource is a pistol.' His first letters from London to his mother and sister are full of enthusiasm. 'I am settled,' says he, 'and in such a settlement as I can desire. What a glorious prospect!' Party-writing seems to have been one of his favourite employments. It was agreeable to his satirical turn, and by raising him into immediate notice gratified his pride, which was unbounded. When recommended by a relation to get into some office, he stormed like a madman, and asserted that 'he hoped, with the blessing of God, very soon to be sent prisoner to the Tower, which would make his fortune.' His writings during his residence in London were numerous; but they failed to procure him a comfortable income, and he was plunged from the highest pinnacle of hope to the depths of despair. In the month of July, 1770, he removed from Shoreditch, where he had lodged, to an apartment in Brook-street, Holborn, where, on the 24th of August following, being literally in a state of starvation, he terminated his existence by poison. He was buried on the following day in the burying-ground of Shoe-lane workhouse.

Chatterton was only seventeen years and nine months old when he died. The controversy as to the Rowleian poems engaged numerous writers of the day; but few people now believe the Rowley poems to be anything else than the production of Chatterton himself.

No monument has yet been erected to the memory of the boy-bard of Bristol. The circumstances attending his death have hitherto prevented any such testimonial; but while the beautiful church of St. Mary Redcliff stands, with which his name is inseparably associated, he will not need any other monument; and in the construction of the Rowley poems, he himself built,

'Ere his young days were spent,
An early but enduring monument.'

The person of Chatterton was, like his genius, precocious. One of his companions says he looked 'like a spirit.' His eyes were uncommonly piercing, and one more so than the other. His habits were domestic, and his affection for his relatives unbounded. The two following passages, one from the Rowleian papers, and the other from one of his acknowledged poems, may be safely pronounced to be from the same hand, notwithstanding the antiquated disguise of the passage from the Rowley papers:—

'The gatherd storme is rype; the bigge drops falle;
The forswat meadowes smethe, and drencke the raine;
The comynge ghastness do the cattle pall,
And the full flockes are drivynge o'er the plaine;
Dashde from the cloudes the waters flott again;
The welkin opes; the yellow levynne flies;
And the hot fierie smothe in the wide lowings dies.'
Ballade of Charitie.

Pale rugged Winter bending o'er his tread,
His grizzled hair bedropt with icy dew;
His eyes, a dusky light, congeal'd and dead;
His robe, a tinge of bright ethereal blue.

'His train, a motley'd, sanguine, sable cloud,
He limps along the russet dreary moor;
Whilst rising whirlwinds, blasting, keen, and loud,
Roll the white surges to the sounding shore.'
Elegy to the Memory of Mr. Thomas Phillips.

The last edition of Chatterton's works is in 3 vols, 1803.

CHAUCER, GEFFREY, a very distinguished name in the long catalogue of eminent Englishmen. He lived much in the court of Edward III., and in familiar intercourse with several members of his family. He was also employed in the public affairs of the realm. But it is as a writer, and especially as a poet, that he claims the notice of posterity. Most of the scholars of his age were accustomed to write in Latin, but Chaucer wrote in the vernacular language of his own age and country: he refined it indeed, but neither his labours, nor those of his contemporaries, Longland, Gower, and Wickliffe, were able to fix the language. The English of Chaucer is so unlike the English of our time, that few persons can read it with ease, and none without the assistance of a dictionary. Yet a little pains would enable any one to master his language and versification, and the pains would be amply rewarded, for his writings are valuable not only as illustrating the manners and habits of the time, but as the productions of a mind eminently poetical. His chief work is a collection of stories, entitled by him, 'Canterbury Tales,' being a series of tales told by the individuals of a party of pilgrims going from Southwark to Canterbury, who had agreed thus to beguile the tediousness of the way. A competent judge, the late Mr. Godwin, says, that 'after the dramas of Shakspeare there is no production of man that displays more various and vigorous talent.'

The æra of Chaucer was the reigns of Edward III. and Richard II., for he was born within a year or two of the accession of Edward, and he died in 1400, soon after the deposition and death of Richard. His most remarkable contemporary was Wickliffe, and it is to the honour of John of Gaunt, one of the sons of King Edward, that he was the associate, friend, and patron, of both these illustrious men.

Chaucer has himself told us that London was the place of his nativity. He was educated at Cambridge, and also at Oxford, and some of his biographers represent him to have gone to Paris, then one of the most celebrated schools of the sciences in Europe. He studied the law, moreover, in the Inner Temple.

While at the university he produced two of his larger works, the 'Court of Love,' and 'the book of Troilus and Cresseide;' but he soon entered on public life. Whether his marriage was the cause or effect of his connexion with the court is not completely ascertained: some would refer his marriage to so late a date as 1370, but this proceeds upon the presumption that his wife was Philippa Pycard, an attendant on Queen Philippa, who appears not to have been married before that year. The old biographers of Chaucer, with some probability, represent him to have been married some years earlier, and to have taken to wife another lady of the court of Queen Philippa, also named Philippa, a daughter of Sir Payne Roet, of Hainault, and sister of Katherine Swinford, the mistress, and afterwards the wife, of John of Gaunt, the mother of the Beauforts.

In 1358 John of Gaunt married Blanch of Lancaster. It was on occasion of this suit or courtship that Chaucer wrote his 'Parliament of Birds.'

In the next year he appears as a soldier. One of the most authentic and interesting memorials we possess of him is a deposition given by him in the suit between Scrope and Grosvenor, on the question of right to a particular figure in their coat armour. The depositions are preserved on the rolls at the Tower. Chaucer deposes among other things, that he was in the expedition of 1359, when Edward III. invaded France, and was then made prisoner by the French, near the town of Retters. How long he remained in captivity is not known, and it is not till 1367 that we meet with him again in the national records, which are almost the only deposits of authentic information concerning the illustrious Englishmen of that period. In that year he had an annual pension of twenty marks granted to him, a sum which his biographer, Mr. Godwin, estimates as equivalent to 240*l.*; the grant is entered on the patent rolls there is proof of the payment of it in the issue roll of the Exchequer of the 44th year of Edward III., and also of the payment of ten marks a year, granted to Philippa Chaucer, his wife.

In 1369 he wrote 'the book of the Duchess,' a funeral poem, on the death of Blanch, duchess of Lancaster.

It is by the light of the national records that we are enabled to trace other facts in the life of Chaucer. In 1370 he had letters of protection, being about to depart beyond sea. In 1373 he was in an embassy to Genoa, to treat on some public affairs. This visit to Italy was one of the most remarkable events in his life, inasmuch as it seems probable that he there saw and conversed with Petrarch, of whom he speaks in the induction to one of his tales. On his return, he had a royal grant of a pitcher of wine, to be taken daily at the port of London, and was soon after made comptroller of the customs in that port. He is found also on the rolls as having a grant of a wardship in 1375, and another of a portion of contraband wool in 1376. About this time it is supposed that he wrote the poem which Pope afterwards modernized, called by him the 'House of Fame.'

In 1377 he was employed in an embassy of a delicate and honourable nature. It was to negotiate a marriage between Richard, prince of Wales, and Mary of France, daughter of the French king.

King Edward III. died in May, 1377. To the early years of his successor are referred Chaucer's poems entitled 'The Black Knight,' 'The Legend of Good Women,' and 'The Flower and the Leaf.' If Mr. Godwin's authorities are sufficient, it would appear that he was in disgrace and misery during much of the period from 1384 to 1389. He is represented as having been implicated in the affairs of John de Northampton, in his struggle for the mayoralty of London, and to have been in consequence driven into exile, flying to Hainault, and afterwards to Zealand, and on his return to England being imprisoned in the Tower, from whence he was not released but at the expense of some disclosures, which are said not to have been creditable to him. It is remarkable, however, and it renders somewhat doubtful what is above stated respecting him, that in 1386 he was returned a knight of the shire for Kent, and that in 1389 he was appointed clerk of the works, an office which he did not long hold.

In the last ten years of his life he seems to have lived retired from public affairs, though receiving from time to time marks of royal favour. A house at Woodstock, which had been assigned to him by the king, and the castle at Donnington, near Newbury, the ruins of which are visible on the right hand of the road from London to Bath, are believed to have been at this period his usual place of abode. It is certain that it was in this part of his life that he wrote the 'Canterbury Tales,' and the tradition, both at Woodstock and at Donnington, is, that portions of the work were written at those places. All his biographers concur in saying that he died in London, and it is certain that he was buried in the Abbey Church of Westminster. The monument which is there erected to his memory was a tribute paid to him, a century and a half after his decease, by Nicholas Brigham.

Chaucer had two sons, Sir Thomas and Lewis; of the latter little is known, but Sir Thomas was speaker of the House of Commons, and, marrying an heiress of the house of Burghersh, obtained with her Ewelme, in Oxfordshire, and other possessions. He had an only daughter, Alice Chaucer, who married De la Pole, duke of Suffolk.

The 'Canterbury Tales' were printed by Caxton, but it was not till 1542 that any general collection of his writings was made and committed to the press; they have been often reprinted. Mr. Tyrwhitt's edition of the 'Canterbury Tales' is justly celebrated for the greater purity of the text, and for the valuable illustrations which he has annexed.

We have noticed in this article Chaucer's principal works, without professing to enumerate all. Warton, in his 'History of English Poetry,' thus sums up the poetical character of Chaucer:—

'In elevation and elegance, in harmony and perspicuity of versification, he surpasses his predecessors in an infinite proportion: his genius was universal, and adapted to themes of unbounded variety: his merit was not less in painting familiar manners with humour and propriety, than in moving the passions, and in representing the beautiful and the grand objects of nature with grace and sublimity. In a word, he appeared with all the lustre and dignity of a true poet, in an age which compelled him to struggle with a barbarous language and a national want of taste, and when, to write verses at all, was a singular qualification.'—*History of English Poetry*, vol. i., p. 457.

CHAUCI, a nation of antient Germany, who lived N.E. of the Frisii, along the coast of the N. ocean, and on both banks of the Visurgis (Weser) and as far as the Albis, or Elbe. To the S. they bordered upon the Catti. Tacitus (*German.* 35) says that their country was extensive and thickly inhabited, and that they were a people distinguished among the Germans for their love of justice and of peace; powerful and yet unambitious, they did not provoke war, but were always ready to resist aggression. They were at one time friends to Rome, and furnished auxiliaries to Germanicus in the war against the Cherusci. (*Annal.* i. 60, ii. 17.) But later, under Claudius, we find the Chauci, under Gannascus, a chief of the Batavian tribe of the Canninefates, crossing the Rhine to make incursions into the Roman province of Germania Inferior, but they were driven away by Corbulo, and Gannascus was killed. (*Annal.* xi. 18.) They afterwards joined in the revolt of the Batavian chief, Civilis. (*Histor.* iv. 79, v. 19.) The Chauci do not appear to have ever been permanently subjugated by the Romans.

CHAUDET, ANTOINE DENIS, a French sculptor, who is entitled to distinction, chiefly for having been among the first who broke through the trammels in which a perverted and bad taste had long confined art. He was born in 1760, at which period a style of design prevailed in which purity and simplicity, both of form and expression, were entirely superseded by affectation and over-attention to unworthy minutiæ of detail.

Chaudet began to study his art at an early age, and obtained the prize from the French Academy for a basso-rilievo of Joseph sold by his brethren, in which, according to the taste of the school in which he was educated, he introduced every sort of accessory—landscape, cattle, a bridge, &c. Upon seeing this work in after-life, he remarked, 'I wonder they did not order me to represent rain. I should have obeyed them.' He afterwards went to Italy, where he diligently studied the antique and the works of Raffaelle. His own productions have great merit, particularly as regards the composition, invention, and improved taste displayed in them; in the execution they are open to criticism. Chaudet was a member of the 'Institut,' and contributed to the 'Dictionnaire de la Langue des Beaux Arts.'

CHAUDIÈRE. [CANADA.]

CHAUFFPIE'. [BAYLE.]

CHAULI'ODUS, a genus of fishes belonging to the abdominal malacopterygians. [STOMIAS.]

CHAUMONT, a town in France, capital of the department of Haute Marne, on the road from Paris to Langres, Belfort, and Bâle or Basel. It is on the left bank of the Marne, and near the right bank of the little river Sure or Suize, which flows into the Marne just below the town; 139 miles E.S.E. of Paris in a straight line, or 148 miles by the road through Provins, Troyes, and Bar-sur-Aube. 48° 7′ N. lat. and 5° 8′ E. long.

Chaumont was originally an insignificant place with a castle called Haute-Feuille, which belonged first to its own lords, afterwards to the counts of Champagne, though it was in the domain of the bishops of Langres, to whom those counts paid homage. The town was walled in by Louis XII., in 1500, and some fortifications were added by his successors, François I. and Henri II. All these fortifications were, in the middle of the last century, falling into ruin; but in 1821 they were repaired, and Chaumont ranks again among fortified places. In 1814, Russia, Prussia, and Austria, here concluded a treaty of alliance against Napoleon.

Chaumont is a handsome town, built on the slope of a hill the town-hall, the portico of the church or chapel attached to the high school, and the hospital, are worthy of notice. The inhabitants, who amount to 6104 for the town, or 6318 for the whole commune, manufacture druggets and other woollens, gloves, which are in high repute, linen, hosiery, cutlery, and candles; and trade in corn, and in sheep fed in the neighbouring country for the supply of Paris. There is a college or high school, an agricultural society, and a theatre.

The arrondissement of Chaumont had, in 1832, a population of 84,965. Bouchardon, an eminent sculptor was a native of this town.

CHAUNA. [PALAMEDEIDÆ.]

CHAUNY, a town in France, in the department of Aisne; it is on the river Oise, the navigation of which commences here, 65 miles N.E. of Paris in a direct line, or 70 miles by the road through Senlis, Compiègne, and Noyon.

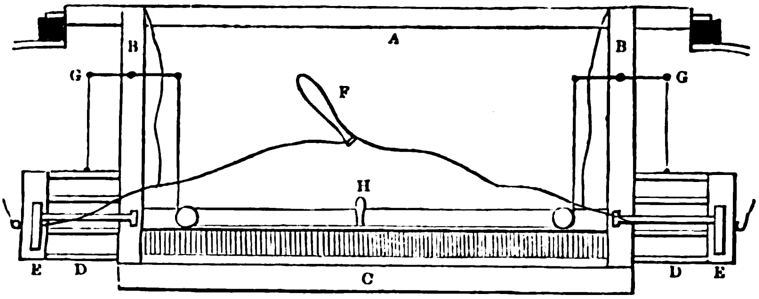
The town is pleasantly situated, and the inhabitants, who amount to 4290, carry on considerable commerce, favoured not only by the navigation of the Oise, but also by the junction here with that river of a canal which communicates with Peronne, St. Quentin, and Cambray. The inhabitants manufacture linens, sacking, cotton-yarn, knit woollen socks, and leather. The looking-glasses of St. Gobain are polished here, for which purpose there is an hydraulic machine. Beside the above articles, the inhabitants trade in wood, grain, cider, oil, horses, &c.

CHAUSSEY, a small island belonging to France, in the English Channel; it belongs to the department of Manche, and is the principal of a cluster of islands nearly opposite to the town and port of Granville, distant about 10 miles. Its length, measured on Brué's map of France, is about 2 miles, the breadth half as much: but the geographical dictionaries of France (Expilly and the *Dictionnaire Universel*), exaggerate these dimensions. This island was once inhabited by hermits, who here sought retirement from the world. At a subsequent period there was a convent of Cordeliers, containing many of those monks; but the English having twice pillaged the convent, the monks withdrew to the main land. Since their retirement the place has been inhabited only in summer, by the workmen who come from Granville to quarry granite, which is here found of good quality, but hard to polish. It is used for building at Granville and St. Malo. The smaller islands of the group are many of them inhabited.

CHECK, a species of chequered cloth, in which coloured lines or stripes cross each other rectangularly, like a chess board. This manner of beautifying webs is probably very antient. Many of the figures in Rosellini's Egyptian work are dressed in chequered cloths. Bishop Anselm's book concerning *Virginity*, written about the year 680, when the art of weaving in this country was probably in a comparatively rude state, contains a distinct indication that chequered robes were then in fashion. 'It is not a web of one uniform colour and texture, without any variety of figures that pleaseth the eye and appeareth beautiful, but one that is woven by shuttles, filled with threads of purple, and many other colours flying from side to side, and forming a variety of figures and images in different compartments with admirable art.' These compartments, defined and bounded by coloured threads, constitute the fabric called a check. Sometimes, however, the check is formed, not by differently coloured threads, but by threads of different fineness and quality. Thus if the chain, warp, or longitudinal yarns of the web be composed of alternate parcels of white cotton and woollen threads, and the transverse yarns or the woof be also composed of such alternate parcels, we shall have a check very distinctly brought forth without any distinction of colour, properly so called.

Cotton handkerchiefs chequed of various colours have been manufactured in India probably from time immemorial under the name of *pullicates*. They were first imported into this country from Madras, whence they derived the name by which this style is still known in the trade. The ground of these has usually a pale buff colour, and is woven with the nankin yellow cotton. Checks in this country are mostly manufactured for the coarser purposes of seamen's shirts, aprons, and bed-gowns of females in the lower ranks of life. The quantity required is so great as to make it a very important branch of business, and to render every mechanism which facilitates the fabrication an object of consequence. Blackburn, in England, and Kirkaldy, in Scotland, are the two chief seats of the check trade, the former in cotton, and the latter, till of late years, chiefly in linen yarns.

For the decussation of woof yarns of different kinds or colours in one web, different shuttles must be in readiness for alternate use. The mode in which this is effected is shown by the figure.



Here we see the picking peg F, which the weaver seizes in his right hand, and with a dexterous jerk causes one of the shuttles lodged in the separate cells at DD, to move from the one side of the loom to the other across the line of the warp, by means of the string which extends from that peg to the drivers or peckers EE, seen at the end of the cells. The three shuttle boxes here shown are so constructed as to be made to slide up and down in a vertical plane, so that each box with its appropriate shuttle may at pleasure be brought on a level with the shuttle race, or open shedding of the warp, and thus be thrown across. These three boxes are suspended by cords from the cross levers G, G, which turn upon centres, in the suspending bars marked B, B, or the swords of the lay; being the levers which make it vibrate backward and forwards in the act of weaving. A represents the cross bar of wood on which the lay C oscillates upon iron gudgeons, or pins driven into each of its ends, and resting upon the upper rails of the loom as shown in section. The under part of the lay is seen at C, and the upper part, called the lay-cap, H, is seized by the weaver's left hand in driving home each shute or shoot of weft. The two pieces of buffalo hide called the drivers or peckers E, E, are perforated, and traverse or slide horizontally upon smoothly polished iron rods. These pieces give the immediate impulsion to the shuttle. The weavers' twitch at the picking peg H must be sufficiently smart to communicate adequate velocity to the shuttle, so as to lodge it in the opposite box, and overcome its friction along the warp race, without however giving it too forcible a pull, which might do injury to its point, or throw it out of the shed. The pin H is made to slide freely from right to left upon the upper bar of the lay, and thus give such motion to the levers G, G, as may bring the proper box opposite to the shuttle driver.

As diversity of woof renders diversity of shuttles necessary, it becomes expedient to shift them rapidly, otherwise the operation would be much impeded. The above plan is not the one originally employed, but is in many respects better. The pin H being fixed by friction only, so as to slide from right to left on the upper shell of the lay, the levers G, G, connected with it may be readily moved, being within reach of the weaver's hand, as he works the lay. The driver, if drawn forward, would present an obstruction to the shifting of the boxes, but this may be easily avoided by an experienced operative.

Mr. Robert Kay, of Bury, son of the most ingenious but persecuted inventor of the fly shuttle, invented the above-described drop box, for making checks, by means of which, [illegible], the weaver could at pleasure use any one of three shuttles without rising from his seat, each shuttle containing a differently coloured weft.

CHEDDAR, a decayed village in Somersetshire, near the stupendous chasm in the Mendip Hills, known by the name of Cheddar Cliffs. Cheddar is said to be derived from *ced*, a conspicuous brow, or height, and *dwr*, water. The village consists of three or four irregular streets. It was formerly a market-town. In one of the streets a beautiful old market-cross is still standing. The population of the parish in 1831 was 1980.

An extensive flat, called Cheddar Moor was, until within these few years, covered with British barrows, or tumuli; but all trace of these has been destroyed by cultivation and enclosure.

Cheddar Cliffs are the sides of a chasm, extending across one of the highest ridges of the Mendip Hills. 'The chasm across the diameter of Mendip is more than a mile in length. The opening yawns from the summit to the roots of the mountain, laying open a sublime and tremendous scene, exhibiting a combination of precipices, rocks, and caverns of terrifying descent, fantastic form, and gloomy vacuity. The approach from the village is extremely picturesque.' (Rutter's *Delineations of the North-Western Division of Somerset.)*

The entrance to one of the caves in these cliffs is nearly 100 feet above the valley; and it is stated to penetrate upwards of 300 feet beneath the rocks. A rough carriage road winds for nearly two miles through the cliffs, until it reaches the summit of the hills.

Nine springs rise from the foot of the rocks, and almost immediately uniting, form a clear and beautiful stream, called Cheddar Water, which falls into the Ax.

The greater part of the land between Axbridge and Cheddar has the appearance of a continued garden. It is sheltered by the Mendip Hills on the N. and E., and is chiefly occupied in the culture of vegetables, large quantities of which are obtained early in the season, and forwarded to Bristol.

CHEESE, caseous matter or caseum, one of the component parts of milk, which may be considered under two points of view; first as uncoagulated, and secondly in a state of coagulation, in which it resembles fibrin and albumen. Uncoagulated caseous matter exists in solution in milk. In order to obtain it, skimmed milk is to be mixed with dilute sulphuric acid, which combines with and precipitates it in the state of a white clot; this is to be washed on a filter to deprive it of the milk which it contains, and it is then to be mixed with water, and digested with carbonate of lime or barytes. The acid combines with the earth, and the caseous matter separated dissolves in the water; it is to be freed by filtration from the earthy salt and butter which are mixed with it.

The filtered solution of caseous matter is of a pale yellow colour, and rather mucilaginous, like a solution of gum. When evaporated, it exhales a smell of boiled milk, and is gradually covered with a white pellicle, which may be removed like that which forms on milk. By evaporation to dryness, the caseous matter remains as a dry mass of an amber colour, which may be redissolved in water.

The aqueous solution is coagulated by acids, even by the acetic acid, especially when heated. When a strong aqueous solution of caseous matter is kept, it changes, emits a smell of old cheese, soon putrefies, and yields ammonia.

Acids act upon caseous matter very much in the same way as upon albumen; with a small portion of acid it forms a compound which is soluble in water; and with a larger quantity of the same acid even, the compound is but slightly soluble; but when it is deprived of the excess of acid by washing, it again becomes soluble in water. The character which principally distinguishes caseous matter from albumen is the precipitation of the former by acetic acid; this precipitate may be indeed redissolved by acetic acid, but it requires much more than albumen does. It is soluble in alcohol. Caseous matter is dissolved by cold weak solutions of the alkalis, without suffering any change; but when they are strong and heated, the caseous matter is decomposed, ammonia is evolved, and the solution contains an alkaline sulphuret; tannin decomposes both the aqueous and alcoholic solution of caseous matter.

It has been already observed that caseous matter may exist both in an uncoagulated and in a coagulated state; what has been already mentioned relates to it in the former condition. The coagulation of caseous matter occurs in a mode which is peculiar to this substance; it is not effected by boiling, but it takes place when either the aqueous solution of caseous matter or milk itself is gently heated with the mucous membrane of the stomach of a young calf, or what is called *rennet*.

According to Berzelius, the action of this substance has not been hitherto explained. In order to investigate the subject, he washed and dried the stomach of a calf, and yet he found that one part of this mixed with 1800 parts of skimmed milk, and heated to 122° Fahrenheit until the operation was complete, so perfectly coagulated the caseous matter that no trace of it remained in solution. When caseous matter coagulated by rennet is burnt, it leaves 6½ per cent. of ashes, which are principally phosphate of lime, precipitated by the rennet from the milk in combination with the caseous matter.

According to Gay-Lussac and Thénard, caseum consists of

Carbon . . .	59·781
Oxygen . .	11·409
Hydrogen . .	7·429
Azote . . .	21·381
	100·

Berzelius, however, considers that this analysis is not correct, because the substance analyzed contained, as he states, lactic acid and butter.

The poorer kinds of cheese consist almost entirely of caseum, while the better sorts contain a considerable quantity of butter mixed with it. Cheese obtained from skimmed milk, which contains but little butter, is hard, translucid, yellowish, and has a greasy lustre, owing to a small quantity of butter which it contains, and which may be separated by æther without altering its properties. When put into water, it swells and softens, but does not dissolve. When strongly heated, it softens without melting, may be drawn into threads, and becomes elastic like caoutchouc. At a higher temperature, it melts, swells, burns with flame, and yields ammonia. Its compounds with acids and alkalies are generally similar to those of uncoagulated caseum; but when the acid is removed by carbonate of lime, the residual caseous matter, being in a coagulated state, is not dissolved by water, as the uncoagulated is under similar circumstances.

When cheese has been long kept, it undergoes peculiar changes; when recently coagulated, it contains nearly 80 per cent. of liquid, which is removed by pressing and drying; it may then be kept for a long time, and becomes more agreeable to the taste. When cheese has not been carefully pressed, it undergoes a peculiar kind of putrefaction; and, according to Proust, two substances, which he calls caseous oxide and caseic acid, are produced. Braconnot has since examined the subject. He mixed about 9 ounces of fresh cheese from skimmed milk with nearly 4½ pints of water, and suffered the mixture to putrefy during a month between 62° and 77° of Fahrenheit; the greater part of the cheese dissolved, and the solution was filtered; it had a putrid smell, but contained no sulphur in any form; and by evaporation to the consistence of honey, it became, after some time, a granular mass, one part of which was soluble and another insoluble in alcohol; the latter was dissolved in water, and the solution, rendered colourless by animal charcoal, yielded by spontaneous evaporation small brilliant slender crystals in the form of rings and cauliflowers; but in order to render these white, it was requisite to dissolve and crystallize them several times. Instead of caseous oxide, Braconnot called this substance *aposepidine* (from ἀπὸ and σηπεδών, produced by putrefaction). It has the following properties it is inodorous, taste rather bitter, but somewhat like that of roast meat; it is gritty between the teeth, heavier than water, easily pulverized; it burns totally; and when heated in a tube open at both ends, part sublimes, without suffering any change, in slender crystals; and another portion is decomposed. When heated on silver, it blackens it, on account of the sulphur which it yields. It is soluble in 22 parts of water at 57° Fahrenheit; the solution readily putrefies and exhales a very disagreeable smell. In alcohol it is but slightly soluble, but most readily so when hot; the solution, on cooling, deposits the aposepidine in the state of a fine white powder. Muriatic acid dissolves a larger quantity than water: neither alum nor persulphate of iron precipitates the aqueous solution; but infusion of galls occasions an abundant precipitate, which an excess redissolves.

The substances contained in the decayed cheese, which the water did not dissolve, were oleic acid coloured brown by an animal matter, a little margaric acid, much margarate of lime, the base of which was derived from the lime existing in the caseous matter, whilst the acids came from the butter.

It has been observed that badly prepared cheese has sometimes, though rarely, become poisonous by keeping. The cause of this change has not been ascertained.

CHEESE. The milk of animals consists of three distinct substances, which are separated from one another by a slight change, which begins as soon as it is exposed to the air. The oily part rises to the surface by its less specific gravity; and when it is collected into a solid mass by agitation it forms butter; the curd, coagulated by the action of any acid, and pressed, becomes cheese; and the fluid which remains is the serum or whey.

In the making of cheese there are certain general principles which are essential, but slight variations in the process produce cheeses of very different qualities; and although the most important circumstance is the nature of the pasture on which the cows are fed, yet much depends on the mode in which the different stages of the fabrication are managed; and hence the great superiority of the cheeses of particular districts or dairies over those of others, without any apparent difference in the pasture. By skill and great attention excellent cheeses are made in places where the pastures are not considered so well adapted to produce milk of a proper quality; and in those countries where the cows are chiefly kept tied up in stalls, and are fed with a variety of natural and artificial grasses, roots and vegetables, superior cheese is often made.

The first process in making cheese is to separate the curd from the whey, which may be done by allowing the milk to become sour, but the cheese is inferior in quality, and it is difficult to stop the acid fermentation and prevent its running into the putrefactive. Various substances added to milk will soon separate the curd from the whey. All acids curdle milk. Muriatic acid is used with success for this purpose in Holland. Some vegetables contain acids which readily coagulate milk, such as the juice of the fig-tree, and the flowers of the *Galium verum*, or yellow lady's bed straw, hence called *cheese-rennet*. Where better rennet cannot be procured, they may be substituted for the most natural curdler of milk, which is the gastric juice of the stomach of a sucking calf. This juice rapidly coagulates the milk as the calf sucks; and the only difficulty is in collecting and keeping it from putrefaction, which begins from the instant the stomach is taken from the calf. The preparation of the *rennet*, as it is called, is a most important part of the process of cheese-making. The following may be considered as the simplest, and perhaps the best. As soon as a sucking calf is killed, the stomach should be taken out, and if the calf has sucked lately, it is all the better. The outer skin should be well scraped, and all fat and useless membranes carefully removed. It is only the inner coat which must be preserved. The coagulated milk should be taken out and examined; and any substance besides curd found in it should be carefully removed. The serum left in it should be pressed out with a cloth. It should then be replaced in the stomach with a large quantity of the best salt. Some add a little alum and sal prunella; others put various herbs and spices, with the view of giving the cheese a peculiar flavour, but the plain simple salting is sufficient. The skins or vells, as they are called, are then put into a pan, and covered with a saturated solution of salt, in which they are soaked for some hours; but there must be no more liquor than will well moisten the vells. They are afterwards hung up to dry, a piece of flat wood being put crosswise into each to stretch them out. They should be perfectly dried, and look like parchment. In this state they may be kept in a dry place for any length of time, and are always ready for use. In some places, at the time of making cheese, a piece of a vell is cut off and soaked for some hours in water or whey, and the whole is added to the warm milk. In other places, pieces of vell are put into a linen bag and soaked in warm water, until the water has acquired sufficient strength, which is proved by trying a portion of it in warm milk. The method employed in Switzerland is as follows:—A dry vell is taken and examined; it is scraped with a knife, and where any veins or pieces of tough membrane appear they are removed. The whole surface is examined and washed carefully, if any dust or dirt has adhered to it; but otherwise it is only wiped with a cloth. A handful of salt is then put into it, and the edges of the vell are folded over and secured with a wooden skewer stuck through it. In this state it forms a ball of about three inches diameter, and is laid to soak twenty-four hours in a dish containing about a quart of clear whey, which has been boiled, and all the curd taken out. The next day the vell is well squeezed, and put into fresh whey; the first infusion being put into a proper vessel, the second is afterwards mixed with it and bottled for use. Half a pint of this liquor of a proper strength is sufficient to curdle forty gallons of milk. Experience alone enables the dairyman to judge of the strength of his rennet; for this purpose he takes in a flat ladle some milk which has been heated to about 95° of Fahrenheit and adds a small measure of rennet. By the rapidity with which it curdles, and the form of the flakes produced, he knows its exact strength, and puts more or less into the cauldron in which the milk is heated for curdling. A simple instrument might easily be invented, by which the exact degree of strength might be ascertained, and a rule given to guide the less experienced; but as long as a man feels a superiority acquired by experience alone, he is not likely to encourage any contrivance which would place others on a level with himself. From this cause even the thermometer has not been introduced generally into any great dairy, nor have any certain rules been given to ascertain the exact heat required in the milk, when the rennet is added, to form the best curd.

There are different kinds of cheese, according to the mode of preparing it: soft and rich cheeses are not intended to be kept long; hard and dry cheeses are adapted to be kept and stored for provisions. Of the first kind are all cream cheeses, and those soft cheeses, called Bath cheeses and Yorkshire cheeses, which are sold as soon as made, and if kept too long become soft and putrid. Stilton and Gruyere cheeses are intermediate; Parmesan, Dutch, Cheshire, Gloucestershire, and similar cheeses, are intended for longer keeping. The poorer the cheese is the longer it will keep; and all cheese that is well cleared from whey and sufficiently salted will keep for years. The small Dutch cheeses called Edam cheeses are admirably adapted for keeping, and form an important article in the victualling of ships.

The Gruyere and Parmesan cheeses only differ in the nature of the milk, and in the degree of heat given to the curd in different parts of the process. Gruyere cheese is entirely made from new milk, and Parmesan from skimmed milk. In the first nothing is added to give flavour; in the latter saffron gives both colour and flavour: the process in both is exactly similar. A large cauldron in the shape of a bell, capable of holding from 60 to 120 gallons of milk, hangs from an iron crane over a hearth where a wood fire is made. The milk, having been strained, is put into this cauldron, and heated to nearly blood-heat (95° to 100°). It is then turned off the fire, and some rennet, prepared as stated above, is intimately mixed with the warm milk by stirring it with the hand, in which is held a flat wooden skimming-dish, which is turned round in the milk while the hand and arm stir it. A cloth is then laid over the cauldron, and in half an hour, more or less, the coagulum is formed. This is ascertained by pressing the skimming-dish on the surface, when the whey will appear on the part pressed. If it is longer than an hour in coagulating, the milk has been too cool, or the rennet not strong enough. The weather has a great influence on the process of the dairy, and there is much yet to be learned by accurate observations with meteorological instruments, especially electrometers. When the curd is properly formed, it is cut horizontally in thin slices by the same skimming-ladle. Each slice, as it is taken off, is poured along the side of the cauldron which is nearest to the operator; by this means every portion of the curd rises successively to the surface, and is sliced thin. The whole is then well stirred, and the cauldron is replaced over the fire. A long staff, with a small knob of hard wood at the end, and which has smaller cross pieces or sticks passed through holes in it at right angles to each other near the end, is now used to stir and break the curd, and the heat is raised to about 135°, which is as hot as the arm can well bear, even when used to it. The cauldron is again swung off the fire, and the curd is stirred with the staff, which is moved round with a regular rotatory motion, the knob running along the angle formed with the side by the bottom of the cauldron, which is in the form of a bowl. After stirring in this manner nearly an hour, the curd is found divided into small dies about the size of a pea, which feel elastic and rather tough under the finger. Experience alone can teach the exact feel they should have. The whey, of which a portion is removed occasionally, now floats at top, and the curd is collected in the bottom by giving a very rapid rotatory motion to the contents of the cauldron by means of the staff. A cloth is now introduced into the bottom, and all the curd collected over it; it is raised by the four corners, and laid on an instrument like a small ladder, which is placed across the mouth of the cauldron. The whey runs out through the cloth, which is a common cheese-cloth woven with wide interstices; and the curd in the cloth is placed in a shape or hoop made of a slip of wood four inches and a half wide, the two ends of which lie over each other, so that the diameter can be increased or lessened. A cord fixed to one end of the hoop is passed with a loop over hooks on the outer surface of the other end, and prevents the ring from opening more than is required. The curd is pressed into this ring with the hands, and the ends of the cloth are folded over it. A round board, two inches thick, and strengthened by cross pieces nailed on it, is placed over the curd, and the press let down upon it.

The cheese-press is a simple long board or frame forming a lever, loaded at one end and moving in a frame at the other; it is lifted up by another lever connected with it, and let down on a strong stick, which stands with its end on the centre of the board last-mentioned. Thus the weight is easily removed or replaced. The hoop containing the cheese is placed on a similar board, and from it the table of the press slopes towards a wooden trough, which receives the whey as it runs out. In an hour after this, the curd is examined; the edges, which are pressed over the ring, are pared off, and the parings are put on the centre of the cheese; a fresh cloth is substituted, and the whole cheese is turned. The ring, which opens readily by unhooking the cord, allows the cheese to come out, and is put on again and tightened. This is repeated two or three times in the day. In the evening, a small portion of finely powdered salt is rubbed on each side of the cheese, and it remains in the press till the next morning. It is now again rubbed with salt, and placed on a shelf with a loose board under it. The wooden ring remains on the cheese for two or three days, and is then taken off. This is the whole process.

During the next six or eight weeks, the cheeses are turned and wiped every day, and a small quantity of fine salt is sifted on the surface and rubbed in with the hand until it will take no more. The cheese-room is always very cool, and little light is admitted. A free circulation of air is essential. The cheeses are in perfection in about six months, and will keep two years. A quantity of elastic fluid is disengaged in the ripening, and forms those round eyes which are a peculiar feature in these cheeses. The smaller and rounder the eyes, the better the cheese is reckoned. They should contain a clear salt liquor, which is called the tears; when these dry up, the cheese loses its flavour. These particulars will give any one unacquainted with the dairy a tolerable notion of the process of cheese-making in general.

In Cheshire the making of cheese is carried on in great perfection, and the greatest pains are taken to extract every particle of whey. For this purpose, the curd is repeatedly broken and mixed, the cheeses are much pressed, and placed in wooden boxes which have holes bored into them. Through these holes sharp skewers are stuck into the cheese in every direction, so that no particle of whey can remain in the curd. The elastic matter formed also escapes through these channels, and the whole cheese is a solid mass without holes, which in this cheese would be looked upon as a great defect. The salt is intimately mixed with the curd, and not merely rubbed on the outside. This checks internal fermentation, and prevents the formation of elastic matter. The whole process of cheese-making is minutely described in the *Agricultural Report for Cheshire.*

Gloucester and Somersetshire cheeses are similarly made, with this difference, that the curd is not so often broken or the cheese skewered, and a portion of the cream is generally abstracted to make butter. After the curd has been separated from the whey and is broken fine, warm water is poured over it for the purpose of washing out any remaining whey, or perhaps to dissolve any portion of butter which may have separated before the rennet had coagulated the milk; for although cream adds to the richness of cheese, butter tends to make it rancid.

Stilton cheese is made by adding the cream of the preceding evening's milk to the morning's milking. The cream should be intimately incorporated with the new milk; great attention should be paid to the temperature of both, and much of the quality of the cheese depends on this part of the process. To make this cheese in perfection, as much depends on the management of the cheese after it is made as on the richness of the milk. Each dairy-woman has some peculiar method which she considers as the best; and it is certain that there is the greatest difference between cheeses made in contiguous dairies. The rennet should be very pure and sweet. When the milk is coagulated, the whole curd is taken out, drained on a sieve, and very moderately pressed. It is then put into a shape in the form of a cylinder, eight or nine inches in diameter, the axis of which is longer than the diameter of the base. When it is sufficiently firm, a cloth or tape is wound round it to prevent its breaking, and it is set on a shelf. It is occasionally powdered with flour, and plunged into hot water. This hardens the outer coat and favours the internal fermentation, which ripens it. Stilton cheese is generally preferred when a green mould appears in its texture. To accelerate this, pieces of a mouldy cheese are sometimes inserted into holes made for the purpose by the scoop, called a *taster*, and wine or ale is poured over for the same purpose; but the best cheeses do not require this, and are in perfection when the inside becomes soft like butter, without any appearance of mouldiness. In making very rich cheeses the whey must be allowed to run off slowly, because, if it were forced rapidly, it might carry off a great portion of the fat of the cheese. This happens more or less in every mode of making cheese. To collect this superabundant butter, the whey is set in shallow pans, as is done with milk when butter is made; and an inferior kind of butter called *whey butter* is made from the cream or fat skimmed off.

Cheeses are frequently coloured, a practice which probably arose from the notion of making the cheese look richer; but now it deceives no one. Yet if some cheeses were not coloured, they would not be so marketable, owing to the association that subsists between the colour and the quality of the cheese. The substance used for colouring is most commonly arnotto. [ARNOTTO.] It is ground fine on a stone, and mixed with the milk at the time the rennet is put in. The juice of the orange carrot, and the flower of marygold, are also used for this purpose. This last give a more natural tint than the arnotto, which is too red. Chedder, a cheese made in Somersetshire, which is highly prized, Stilton, Derby, and some other cheeses, are never coloured: Cheshire slightly; but Gloucester and North Wiltshire deeply. Foreign cheeses are only coloured very slightly, if at all; the Dutch cheeses are made in a very similar manner to the Gloucester cheeses, but the milk is generally curdled by means of muriatic acid or spirits of salt: and great care is taken to prevent fermentation, and to extract the whole of the whey. For this purpose the curd is repeatedly broken and pressed; and before it is made up into the round shape in which it is usually sold, the broken curd is well soaked in a strong solution of common salt in water. This diffuses the salt throughout the whole mass, and effectually checks fermentation. When the cheeses are finally pressed, all the whey which may remain is washed out with the brine; salt is likewise rubbed over the outside, and they are set to dry on shelves in a cool place. The flavour of the cheese is perhaps impaired by the stoppage of the fermentation; but it never heaves, and it acquires the valuable quality of keeping well even in warm climates. From the place where this cheese is commonly made, it is known by the name of Edam cheese. A finer cheese is made at Gouda and other places, by imitating the process in making Gruyere cheese; but this cheese is always full of small cavities, and will not keep so long as the Edam. The cheese most commonly met with in Holland is a large kind of skim-milk cheese, which is made very like Cheshire cheese. It grows hard and dry, and has not much flavour. To supply this defect, cummin seeds are mixed with the curd, which those who are accustomed to it consider a great improvement. On the whole it is a better cheese than our Suffolk skim-milk cheese, and forms an important part of the provisions usually stored for a Dutch family. In France the Roquefort cheese is compared to our Stilton, but is much inferior, although a good cheese. The little cheeses made from cream and folded in paper, called Neufchâtel cheeses, are imported from France as a delicacy. They can be easily imitated, being nothing more than cream thickened by heat, and pressed in a small mould. They undergo a rapid change, first becoming sour and then mellow, in which state they must be eaten.

A small cheese, much relished by all ranks, is made in the north of Germany in the simplest manner. It is usually made from milk from which the cream has been taken off to make butter,—although the entire milk is much better. This is curdled by being placed near a fire. When it has become somewhat sour, it is put into a linen bag, and all the whey well pressed out. When it is tolerably solid, it is broken by the hand in a tub, and made very fine. It remains in this state several days, until a considerable alteration takes place, and the putrid fermentation begins, as is readily perceived by the odour. It is then taken in small portions, and formed into flattened balls three or four inches in diameter, by beating them in the hands. These balls are ranged on a board, and set to dry. A portion of carraway seed is generally mixed with the curd. In a few days the mellowing goes on, and the centre becomes very soft. In this state it is a great dainty for those who disregard a pungent and fetid smell. They are sometimes placed in the smoke of a chimney where the putrid fermentation is checked and confined to the centre by the pyroligneous acid arising from a wood fire. They remain in the chimney a considerable time; and when they are used the outer part is peeled off like the rind of an apple. A whole cheese is a mere mouthful. It gives a relish to the sour black rye bread generally eaten by the lower orders.

The green Swiss cheese, commonly called *Schabzieger*, which is made in the canton of Glarus, and is by many persons highly esteemed, is made somewhat in the same manner. The curd is pressed in boxes with holes to let the whey run out; and when a considerable quantity has been collected and putrefaction begins, it is worked into a paste with a large proportion of a certain dried herb reduced to powder. This herb, called in the country dialect *Zieger kraut* (curd-herb), is the *Melilotus officinalis*, which is very common in most countries, and has a peculiar aromatic flavour in the mountains of Switzerland. The paste thus produced is pressed into moulds of the shape of a common flower-pot, and the putrefaction being stopped by the aromatic herb, it dries into a solid mass, which keeps unchanged for any length of time. When used it is rasped or scraped, and the powder mixed with fresh butter is spread upon bread. It is either much relished or much disliked, like all those substances which have a peculiar taste and smell.

A species of cheese or rather hard curd is made in the mountains of Switzerland from the whey which has run from the common cheese made of the whole milk. It is called *serré*. When the Gruyere or the Jura cheese, which is often sold by the same name, has been put under the press, a quantity of fermented whey, about two or three gallons, is poured into the cauldron with the new whey, and the whole is heated over the fire till a thick scum rises. This is taken off when the whey is nearly boiling, and put into a square box with holes in it; the whey which remained mixed with the curd, and which is now very blue, is allowed to run out, and a small pressure assists it. When a cheese of sixty pounds has been made, the serré will often weigh twenty pounds. This mass of curd readily dries on the shelf, and becomes hard. It has little flavour, but it serves the people on the mountains for bread. They cut slices of it, spread some butter over, and put a thin slice of cheese upon this: washed down with a cup of fresh or of fermented whey, it forms the chief food of the mountain herdsmen. The only luxury indulged in is an occasional glass of *kirsch-wasser*, a spirit distilled from cherries, or of gentian brandy, from the root of the *Gentiana officinalis*.

When a cheese which has been much salted and kept very dry is washed several times in soft water, and then laid in a cloth moistened with wine or vinegar, it gradually loses its saltness, and from being hard and dry, becomes soft and mellow, provided it be a rich cheese. This simple method of improving cheese is worth knowing. It is generally practised in Switzerland, where cheeses are kept stored for many years, and if they were not very salt and dry they would soon be the prey of worms and mites. A dry Stilton cheese may thus be much improved.

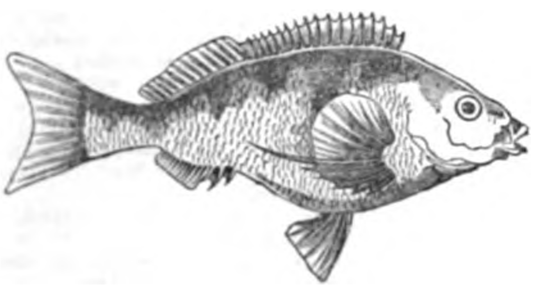
The cheese trade is one of considerable importance.

CHEESE-RENNET, a wild flower with square stems, shining whorled leaves, and loose panicles of small yellow flowers. It is the *Galium verum* of botanists, and derives its popular name from having been formerly employed to curdle milk.

CHEILI'NUS. [LABROIDES.]

CHEILODA'CTYLUS, a genus of fishes, of the section *Acanthopterygii*, and family *Scienoïdes*. Characters:—mouth small; dorsal fin with numerous spiny rays; lower rays of the pectoral fins simple and continued beyond the membrane.

Cheilodactylus monodactylus (*Chætodon monodactylus*, Carmichael; *Linn. Transactions*, vol. xii.), will serve to illustrate this genus. This fish is about eighteen inches in length; the body is somewhat oval and compressed; the teeth are small and crowded; the pectoral fin is large, and has fifteen rays, the six lower of which are simple and protrude beyond the membrane; the sixth ray from the bottom is very much elongated. The colour is olive, or bronze, with six dark stripes on the back: the fins are blackish, with the exception of the pectorals, which are amber-coloured.



[Cheilodactylus monodactylus.]

This species is very common on the coast of the small island of Tristan da Cunha, and feeds upon the *fucus pyriferus*.

CHEILODI'PTERUS (Lacépède), a genus of fishes of the section *Acanthopterygii*, and family *Percidæ*. Technical characters:—Body rather short; pre-operculum double-edged, the edges finely serrated; scales large, easily dislodged, continued on to the pre-operculum; the two dorsal fins widely separated.

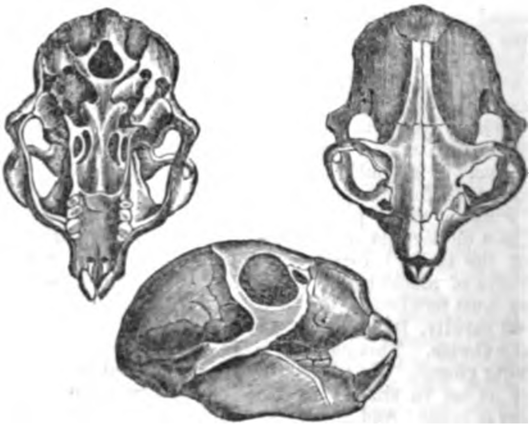
The characters here detailed are those of the genus Apogon, from which the present genus differs chiefly in having the jaws furnished with long and pointed teeth. But three species of Cheilodipterus are known; they are all of small size, and furnished with slender longitudinal stripes. *C. octo-vittatus*, as its name implies, has eight stripes. *C. quinquelineatus* has five longitudinal black stripes, the ground colour of the body being silvery white: it is about four inches in length, and comes from the Society Islands. The third species, *C. Arabicus*, is of an olive green colour above, and has the under parts silvery with a pinkish hue; this species has from fourteen to seventeen longitudinal stripes.

As an example of the genus Apogon, of which there are several species, we may notice the Apogon, *Rex Mullorum*, or Roi des Rougets (Cuvier): this species rarely exceeds six inches in length, and is of a beautiful red colour with three large black spots on the back; one under each of the dorsal fins, and one towards the tail; the whole surface is also sprinkled with small black dots. The remaining species are also small, and most of them are of a red colour; a few have been found off the coast of New Holland, but most of them frequent the Indian seas.

CHEIROGA'LEUS. [LEMURIDÆ.]

CHEIRO'MELES. [CHEIROPTERA.]

CHEI'ROMYS (Zoology), the scientific name for the Aye-Aye, a singular quadruped (which must not be confounded with the Ai, or Sloth [AI], from which it very strongly differs in organization, though its habits are lazy), discovered by Sonnerat at Madagascar, and described by him in the second volume of his 'Voyage aux Indes,' under the name of Aye-Aye, which, it appears, is an exclamation of the natives; and it is conjectured that the name was attached to the animal in consequence of a supposed resemblance to its cry. Sonnini, who formed the genus, observing that it is the only species known, censures Gmelin with some reason for denominating it *Sciurus Madagascariensis* (Madagascar Squirrel), because a quadruped of the latter genus really exists in Madagascar. Cuvier places the form next to the Flying Squirrels, *Polatouches* (*Pteromys*), and immediately before the Rats (*Mus*, Linn.), remarking that the lower incisors are much more compressed, and especially more extended from before backwards, than those of the squirrels, and resemble ploughshares (socs de charrue). The feet, he adds, have all five toes, of which four of those on each anterior extremity are elongated, the middle toe being much more slender than the others; in the hind feet, the great toe is opposable to the others, so that in this respect the animal is among the Rodents what the Opossums (Sarigues) are among the Carnassiers. The structure of the head, he continues, is very different from that of the other Rodents, and has more relation to the Quadrumana.



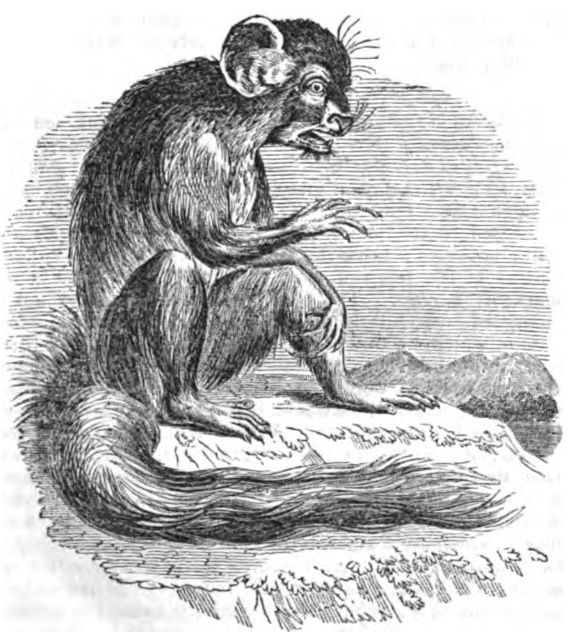
[Skull of Aye-Aye.

Dental formula: incisors, $\frac{2}{2}$; molars, $\frac{4-4}{3-3} = 18$.

Sonnerat says that the Aye-Aye, which is found chiefly if not exclusively on the western part of the island, does not approach any genus, but that it leans towards the Maki, the Squirrel, and the Ape. Its large and flat ears, he observes, resemble much those of a bat; and states that its principal character, and a very singular one it is, is the middle toe or finger of the fore foot, the two last joints of which are very long, slender, and denuded of hair. This member, he adds, is useful to it in drawing worms out of holes in the trees, and that it seems also to be of service in holding on to the branches of trees. He says that it appears to be a subterranean animal, and does not see during the day, and that its eye resembles in colour that of the owl. He describes it as being very slothful, but good tempered, remaining always at rest and requiring a good deal of shaking to make it move. The subject of his observations lived two months upon no other nourishment than cooked rice, and it fed itself with its two fingers like the Chinese with their chopsticks. All the time M. Sonnerat had this animal alive, he never saw it carry its tail elevated like the squirrel. It always dragged. But Buffon's figure, or rather that of the *Supplement*, sets the tail up, notwithstanding the observation in the text.

Buffon (*Supplement*) states, that he examined the skin of one which Sonnerat gave to the Cabinet du Roi, and that it appeared to him to approach the squirrels more than any other race; and also to bear some relation to the Tarsier. The length of the animal, measured in a straight line from the tip of the muzzle to the insertion of the tail, was one foot, two inches, two lines (French), and following the curvature of the body, one foot six inches and six lines, and the length of the stump of the tail was one foot three inches. In the anterior extremities, the length of the internal finger, which acts in some measure as a thumb, was one foot one line, and the nail six lines; the next finger, or first finger, two inches nine lines, and the nail six lines; the second, which is much more delicate and slender, being only one line in thickness, was two inches and seven lines long, and the nail three lines. The third finger was three inches, two lines in length, and the nail six lines. The fourth finger was one inch, nine lines, and the nail six lines. The hind feet to the extremity of the fingers were three inches and two lines long. This was a female.

Buffon describes the colour as a musk brown mixed with black and grey-ash. On the head, round the eyes, on the body, thighs and legs, the colour was deep musk, in which, nevertheless, black predominated upon the back and many parts of the body and legs. The tail was entirely black; the sides of the head, the necks, the jaw, and the belly were greyish. There were woolly hairs of this grey colour below the great black or white hairs, of two or three inches long, which were on the body and legs; but the legs and thighs were of a reddish brown. Black predominated at the approach of the feet, which were covered with small hairs of that colour. The head was like that of a squirrel, and the ears large, naked, erect, and round at their extremities, with a wide opening.



[Cheiromys Madagascariensis.]

This animal is the *Aye-Aye Squirrel* of Pennant. Shaw considered it to be a species of *Lemur*, and Schreber named it *Lemur psilodactylus*, a name adopted by Shaw. Our figure is reduced from that given by Sonnerat.

CHEIRONECTES, or **CHIRONECTES** (Mammalogy), Illiger's name for a genus of Marsupial animals. [DIDELPHIDÆ.[*]]

CHEIRO'PODA[†], **CHEIROPEDS**, a name proposed by Mr. Ogilby for all the mammiferous animals that are possessed of hands. The following is an abstract of Mr. Ogilby's arrangement of his Cheiropeds.

Class - - Mammalia.
Order - - Cheiropoda.
Mammals with opposable thumbs on the
anterior extremities only - - - - - Bimana.
On both anterior and posterior extremities, Quadrumana.
And with anthropoid teeth.
Monkeys of the Old World.
———— abnormal teeth,
Lemuridæ.
On the posterior extremities only - - Pedimana.
And with anthropoid teeth,
Monkeys of the New World.
———— rodent teeth,
Cheiromys.
———— abnormal teeth,
Didelphidæ.

Observations, commenced in 1829 and continued for more than six years, have assured this zoologist that the non-opposable character of the inner finger of the anterior extremities, which he first remarked in *Mycetes Seniculus*, is not confined to that genus, but extends throughout the whole of the genera of the South American monkeys, individuals of all of which have, he states, been seen by him in a living state. In none of them, consequently, he observes, does a true thumb exist on the anterior limbs; and he considers that it follows as a further consequence that the whole of them have been hitherto incorrectly referred to the *Quadrumana* by zoologists generally. He speaks of D'Azara's remark, that the anterior extremities of some of the species observed by him had five fingers, originating on the same line with each other, as a solitary exception, and as having been either unnoticed by other authors, or to have been considered as unworthy of attention, so entirely were they at variance with the preconceived notions of all.

As Mr. Ogilby's views on this subject differ from those of other zoologists, and appear to be the result of much attentive examination, principally made on the living animals, we proceed to give the substance of his 'observations on the opposable power of the thumb in certain *mammals*, considered as a zoological character; and on the natural affinities which subsist between the *Bimana*, *Quadrumana*, and *Pedimana*,' as set forth in the abstract of that paper in the 'Proceedings of the Zoological Society of London,' read on the 8th of March, 1836.

'Of the eight natural genera which include all the known monkeys of the western hemisphere, one, *Ateles*, is entirely destitute of a thumb, or has that member existing only in a rudimentary form beneath the skin. In five others, *Mycetes*, *Lagothrix*, *Aotus*, *Pithecia*, and *Hapale*, the anterior thumbs (using the ordinary expression for them) are placed absolutely on the same line with the other fingers, are of the same form with them, act invariably in the same direction, and are totally incapable of being opposed to them. In the two remaining genera, *Cebus* and *Callithrix*, the extremities of the anterior limbs have a greater external resemblance to the hands of man and of the monkeys of the Old World: the internal finger is placed farther back than the general line of the other fingers, and has, on that account, when superficially noticed, the semblance of being opposed to them; but, as has been correctly observed by D'Azara, with reference to *Cal. capucinus*, it is less separated than in *man*: it is, besides, of precisely the same slender form with the rest, is weaker than them, absolutely without power of opposition to them, and habitually acts in the same direction with them. The impression derived from contemplating the hands of the Old World monkeys might induce the belief that the extremities of the *Cebi* are similarly constituted; but if the knowledge that in *Mycetes*, *Pithecia*, &c., there are no opposable thumbs, leads to a close observation of the anterior extremities of the *Cebi*, it will be found that they do not act as hands, and cannot be considered as possessing the powers of those organs. From innumerable observations of many species of that genus, Mr. Ogilby states that it was very evident, notwithstanding the fallacious appearance occasioned by the backward position of the organ, that they had not the power of opposing the thumbs to the other fingers in the act of prehension; and, in fact, their principal power of prehension seems to be altogether independent of the thumb, for, generally speaking, that member was not brought into action at all, at least not simultaneously with the other fingers, but hung loosely on one side, as Mr. Ogilby has seen it do, in like circumstances, in the *Opossums*, *Phalangers*, and other arboreal *Mammals*: when actually brought into play, however, the thumb of the *Cebi* invariably acted in the same direction as the other fingers. *Cebus* consequently agrees in the character of non-opposableness of thumb with the nearly allied genera. And in this hitherto unsuspected peculiarity zoologists obtain a far more important character by which to distinguish the monkeys of the Old and New World than that hitherto relied on, the comparative thickness of the *septum narium*, or than the accessory aids afforded by the absence of cheek-pouches and callosities. Hence, according to Mr. Ogilby, as the monkeys of America have now been ascertained to be destitute of anterior hands, they can be no longer included among the *Quadrumana*; and he proposes, in consequence, to regard them as *Pedimana*. He considers that the latter series, the monkeys of America, form a group parallel to that of the monkeys of the Old World among the *Quadrumana*: and viewing the *Quadrumana* as consisting of two primary groups, that of which *Simia* forms the type, and the *Lemuridæ*, he proceeds to analyze the *Pedimana*, in order to determine whether any group analogous to the *Lemurs* exists in it. He finds such a group in the association of the genera *Didelphis*, *Cheironectes*, *Phalangista*, *Petaurus*, and *Phascolarctos* (together with a new genus, *Pseudochirus*, which he has found it necessary to separate from *Phalangista* as at present constituted); and for this association he uses the name of *Didelphidæ*. Aware that the modifications observable in the dentary systems of these several genera have been regarded by many zoologists as betokening a difference of regimen, which has led to their being viewed as constituting distinct families, he, in the first place, states, as the result of his observation of the habits of the numerous species of all these genera which have been, from time to time, exhibited in the Society's gardens, that there is little or no difference, in this respect, between the *Opossums* and *Phalangers*, but that all are equally omnivorous; and then proceeds to discuss the modifications that exist among them in the number and form of the several kinds of teeth, which are not, in his estimation, so very different in reality between the *Opossums* and *Phalangers* as they appear to be at first sight. In further support of his opinion that this association of genera forms a natural family, Mr. Ogilby refers to the gradual and uninterrupted transition from the naked-prehensile-tailed *Opossums* of South America, through the equally naked-tailed *Couscous*, *Balantia*, of the Indian Isles, to the true *Phalangers*; and from these to the *Petaurists* directly on the one hand, and, by means of the *Pseudocheirs*, to the *Koalas* on the other.

---

[*] N.B. *Chironectes* (Ichthyology) is the name adopted by Cuvier for a genus of Acanthopterygians (*Antennarius* of Commerson), comprising some of those fishes popularly known under the name of *Anglers*. This may be the source of confusion both to the hearer and the reader, and the name of the latest date should be changed.

[†] Χείρ, a hand; πούς, a foot.

'On the prehensile power of the tail Mr. Ogilby particularly insists, as on a faculty possessed by the greater number of the *Pedimana*, and as one which is, in truth, almost confined to them; only three known genera belonging to other groups, *Synetherus*, *Myrmecophaga*, and *Cercoleptes*, being endowed with it. He remarks on this faculty as on one of considerable importance, affording as it does, in some degree, a compensation for the absence of opposable thumbs on the anterior limbs. Combined with the prehensile tail, in every known instance, whether among the *Pedimana* or in other groups, is a slowness and apparent cautiousness of motion, not observable in any of the *Quadrumana*, except in the *Nycticebi*. In none of the true *Quadrumana* is the tail prehensile.

'Another evidence of the distinctness, as two groups, of the *Quadrumana* and the *Pedimana*, is furnished by their geographical distribution. The *Quadrumana* are strictly confined to the limits of the Old World; the *Pedimana* [illegible] as exclusively to the New World; for Mr. Ogilby considers the continent of Australia to belong more properly to America than to Asia. The very few apparent exceptions that occur to this latter position are in the presence of some species of *Phalangers* in the long chain of islands that connect the south-eastern shores of Asia with the north-eastern coast of Australia; islands which may, in truth, be fairly regarded as belonging partly to the one and partly to the other, and the productions of which might consequently be expected to partake of the character of both.

'Mr. Ogilby subsequently adverts to another *Pedimanous* animal, the *Aye-Aye* of Madagascar, constituting the genus *Cheiromys*; respecting the affinities of which he speaks with hesitation, because, having never had an opportunity of examining the animal itself, he is acquainted with its characters only at second hand. He is, however, disposed to regard it as representing a third group among the *Pedimana*, to be placed in a station intermediate between the *Monkeys* of the New World and the *Didelphidæ*. With the latter he would, in fact, be disposed to associate it, were it not destitute of the marsupial character which belongs to all the other animals comprised in that group. In some of the *Didelphidæ*, the *Phalangers* and *Petaurists* especially, there is a marked approximation to that rodent form of incisor teeth which obtains in *Cheiromys*, and which has hitherto been regarded as especially attaching to it an abnormal character.

'*Man* is the only other animal furnished with hands, and however distinct he may be as regards his moral and intellectual powers, he must, zoologically, be considered on physical grounds. By his structural characters he becomes associated with all those of which mention has previously been made in Mr. Ogilby's communication; although he unquestionably constitutes among them a peculiar group, sensibly exalted above the rest, as well as above all other *Mammals*.'

CHEIROPTERA * (Zoology), the name of a natural family or division of mammiferous animals; the *Bats* or *Flittermice*, of the English; *Fledermäuser* of the Germans; *Vespertiliones* of the Latins; *Pipistrelli* and *Nottoli* of the Italians; *Chauve-souris* of the French; for we agree with those zoologists who are of opinion that *Galeopithecus*, which, taking its organization and habits into consideration, can hardly be called a bat, should be rather referred to the *Lemuridæ* than to this family, though its place among created beings is, as yet, hardly agreed on. [GALEOPITHECUS.]

The animals then which we consider to belong to this wing-handed family are those which would come under the genus *Vespertilio* of Linnæus. They all have the faculty of sustained flight, and their organization and habits point them out as a separate and well-defined group, distinguished by a folding extension of the membranous skin, which, rising from the sides of the neck, is spread between their fore-feet and their fingers.

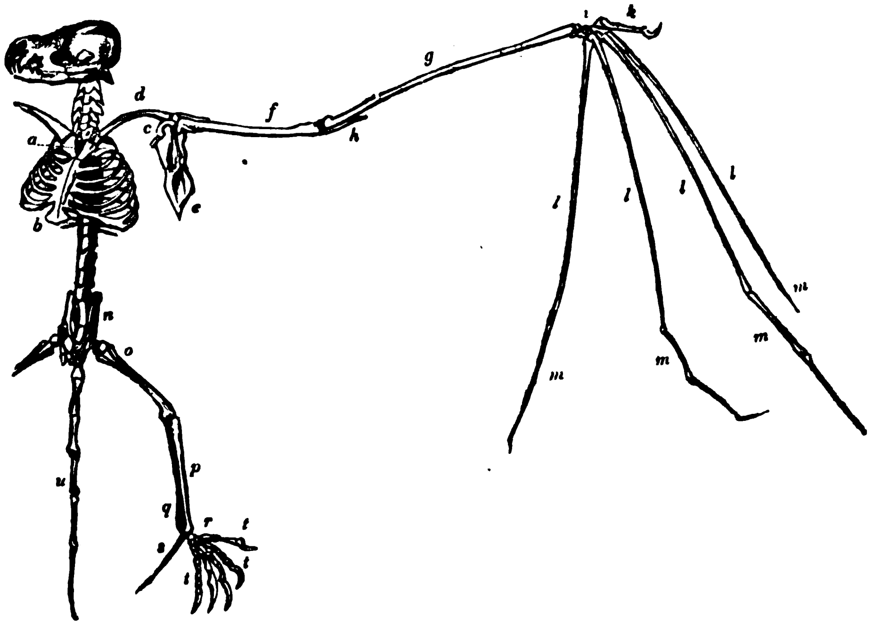
ORGANIZATION.

Skeleton. *The skull* is thin, and there is a marked difference between that of the so called frugivorous group (*Pteropus* and *Cephalotes*) and the true or insectivorous Bats, *Vespertilionidæ* of Gray, the former being much more elongated than the latter. The bony *tentorium*, so strongly developed in the majority of the carnivora, is entirely absent; but there is a considerable development of the auditory portion of the temporal bone. The occipital bone is remarkably narrow. The superior maxillary is very much elongated, particularly in the so called frugivorous order, a term which we would change for omnivorous, for their well developed sharp canines, and the structure of some of their other teeth, would seem to be more trenchant than fruit-eating habits alone would require; and indeed Cuvier, in the last edition of the 'Règne Animal,' says of the genus *Pteropus*, 'they live principally on fruit, of which they destroy a great deal; but they know, nevertheless, how to pursue birds and small quadrupeds,' and we think it highly probable that they occasionally prey on the large insects which are found in the climates they inhabit. All the family have four great canine teeth, but there is considerable difference between the molars of the fruit-eating section and of that whose diet is confined entirely to insects, the crowns of the former being comparatively blunt and hollowed out or grooved lengthwise, while those of the latter are shorter and sharper, and beset with points. The molars vary in number in the different genera, the smallest development being three in each jaw, and the largest five above and six below, or *vice versâ.* The incisors set in the small and short intermaxillary bones vary also in the different genera. The smallest number in the upper jaw is two, and the largest four; the smallest number is also two in the lower jaw, and the largest six. The *atlas* is of considerable size, but the *dentata* is not large. The greatest number of the *dorsal vertebræ* is twelve, the smallest eleven. The canal for the spinal chord is large in these vertebræ. The *lumbar vertebræ* vary in number; the smallest number is four, the largest seven. The *ossa coccygis* are slender and elongated: their use seems only to be to assist (somewhat like a spreat) in spreading the interfemoral portion of the membranes, by the aid of which the animal sails in the air; their smallest number is six, and their largest twelve; for in the majority the tail extends to the margin of the membrane, while in some it protrudes beyond it, and in others it does not reach more than half way. In *Pteropus* there is no trace of these bones.

---

* χείρ, a hand and πτερόν, a wing.

The *ribs* are remarkably long, except the first pair, which is very short, and remarkably broad, especially in the cartilage, which is ossified; and the *sternum* is highly developed, as might be expected from the exigencies of the animal. The anterior portion is expanded laterally into what is termed the *manubrium,* which seems to be largest in the *Horse-shoe Bat* (*Rhinolophus*), forming a suitable point of attachment for the strong, long, arched clavicles, which are articulated both to the *sternum* and *scapula;* the latter is very large and elongated, and the lower surface is very concave. The *fossæ* for the strong muscles, both above and below the spine of this bone, are deeply marked. The habits of the animal required an ample development of these parts to give the shoulder the required solidity for working the mechanism of the wing, and we accordingly find the strength thrown into the *sternum, clavicles,* and *scapula.* But these same habits would have rendered the rotatory motion of the fore-arm worse than useless, for such a disposition would have weakened the power of the limb in beating the air with the extended membrane. We accordingly find that this power is absent: the *ulna,* indeed, is remarkably small, and in some the bone is merely rudimentary, forming a mere flat process, only partially separated from the *radius:* there is no *olecranon* (elbow) The *humerus* is long, slender, and cylindrical, and the head of the bone large and round. The structure of the *wrist* is peculiar: first come two bones next to the *radius,* and on these that bone rests; one of these is very large, and the other very small—the second series consists of the usual four bones; but it is in the bones of the *metacarpus* and of the fingers that the adaptation of the osseous parts of the animal to its necessities is, perhaps, most strongly shown. These, with the exception of the phalanges of the thumb, are greatly elongated, and run outwards and downwards to the edge of the wing-membrane, something after the fashion of the whalebones that assist in spreading an umbrella. The first finger is the shortest, and extends to the upper angle of the outer edge of the membrane; the second is generally the longest, and the third and fourth nearly of a length; the three last descend to the lower edge of the membrane. The *pelvis* is straight and lengthened, and rather wider below than it is above, the *ilia* being very narrow and elongated. The *ossa ischii* approach even to the contact of their tuberosities, and in some examples touch the *ossa coccygis.* The *ossa pubis,* in some species, recede from each other, the intermediate space being filled by a ligament; and in others these bones touch each other in the male, and are separated in the female. The *sacrum* and *ilia* are anchylosed early in life. The lower extremities do not offer any very striking differences from those of other mammifers, excepting that the thighs being directed outwards, the bones of the leg are partially turned round as it were (the *fibula* appearing at the inner side of the *tibia,* and a little posterior to that bone), and that there is a singularity about the heel. An elongated delicate bony process is given off from the back part of the foot, is inclosed in the margin of the interfemoral membrane, and proceeds about half way to the tail. Cuvier thought this a portion of the *os calcis;* Daubenton, that it was a distinct bone: and Meckel, that it is only a development of the tuberosity of the bone, disunited from its body. Mr. Daniell, on the 11th November, 1834, exhibited to the Zoological Society of London skeletons of the male and female *Pipistrelle* and *Noctule Bats,* for the purpose of pointing out a peculiarity in the female, connected, as he conceives, with the mode of parturition, described under the head of '*Habits*'. This peculiarity consists of a prolongation of the *os calcis* along the margin of the membrane, extended between the hinder extremities and the tail, of much greater length and strength in the female than in the male. By means of this process, Mr. Daniell believes the female to be capable of giving greater tension to the pouch formed of that membrane for the reception of the young in the act of parturition.



[Vespertilio murinus. Skeleton of Bat.]

a, manubrial bone; *b,* xiphoid cartilage; *c,* coracoid bone; *d,* clavicle; *e,* shoulder-blade; *f,* humerus: *g,* radius; *h,* rudiment of ulna; *i,* carpus (wrist); *k,* metacarpus of thumb, terminated by a hook-shaped phalanx; *l,* metacarpal bones of the fingers; *m,* digital phalanges; *n,* pelvis; *o,* femur; *p,* tibia; *q,* fibula; *r,* tarsal bones of foot; *s,* styliform appendage to os calcis; *t,* metatarsus and toes; *u,* tail.

Digestive Organs. Besides the difference of the molar teeth in the fruit-eating (or omnivorous) and the insectivorous Bats, already alluded to, the stomach and intestines present a remarkable corresponding variance. The stomach of the former is very complicated, and the intestines very long: in *Pteropus,* for example, they are seven times as long as the body. In the latter the stomach is very simple, and merely divided into the cardiac and pyloric portions, and the intestines are not more than twice the length of the body. These differences, together with that of the greater or less development of the tail, which is powerful, generally speaking, in the true insectivorous bats, and either absent, rudimentary, or comparatively inefficient in the fruit-eaters, which last do not require to turn so rapidly as the desultory flight of the prey of the former makes it necessary for them to do, form, it is true, a marked distinction between the two groups; but we are, notwithstanding, of opinion that very few Bats confine themselves entirely to a vegetable diet.

Nervous System and Senses. Taste.—This sense is probably well developed. In *Pteropus* the surface is rough. In *Phyllostoma* there is a peculiar structure, the tongue being suctorial by the aid of several wart-like elevations, capable of forming a disk for extracting the juices of fruits or the blood of animals through the operation of muscular fibres acting on these wart-like elevations by a tendon transmitted to each. *Smell*, most probably acute, especially in the *Rhinolophinæ*. *Sight and Hearing.*—The eye is diminutive in the Insectivorous Bats, and of fair proportion in the other section; but this is compensated for in the former by the extraordinary development of the external and part of the internal *auditory apparatus*, while that of the latter offers nothing remarkable. The external ear of the British long-eared bat (*Plecotus auritus*) almost equals the body in length. *Touch.*—This, or a sense analogous to it, must be highly developed. Spallanzani—we cannot compliment him on his humanity—extracted the eyes of bats and covered the empty sockets with leather; yet, in this condition, they flew round his room, avoiding the sides, never striking against anything, and flying out of the door without touching the door-case. In flying through a sewer which made a right angle, they turned at the proper point, though at a distance of two feet from the walls. They found their resting-place on a cornice, and flew through threads, suspended perpendicularly from the ceiling, without touching them, though scarcely farther apart than would admit their extended wings; and they avoided all obstacles with equal facility when the whole head was covered with varnish. But, according to the experiments of Carlisle, the British long-eared bat was entirely at a loss if, when blinded, its ears were stopped,[*] for in that condition the blinded bats struck against the sides of the room, and seemed to be quite unaware of their situation. The following additional note to the English translation of Blumenbach, however, corroborates Spallanzani. 'Bats have been supposed to possess a peculiar power of perceiving external objects, without coming actually into contact with them. In their rapid and irregular flight, amidst various surrounding bodies, they never fly against them; yet it does not seem that the senses of hearing, seeing, or smelling, serve them on these occasions, for they avoid any obstacles with equal certainty when the ear, eye, and nose, are closed. Hence naturalists have ascribed a sixth sense to these animals; it is probably analogous to that of touch. The nerves of the wing are large and numerous, and distributed in a minute plexus between the integuments. The impulse of the air against this part may probably be so modified by the objects near which the animal passes, as to indicate their situation and nature.' Cuvier, in his *Leçons d'Anatomie Comparée*, had, in a great measure, solved the mystery by observing, as is remarked in the note just quoted, that the whole surface of the flying membrane, on both sides, is endowed with extraordinary sensibility, and may be considered as one continuously expanded organ of touch. Nor is this the only peculiarity connected with the integument of the bats, for, in the genus *Nycteris* there exists a power of inflation to such a degree, that when the faculty is exerted the animal looks, according to Geoffroy, like a little balloon fitted with wings, a head and feet. The subcutaneous tissue is the part inflated, and as the skin adheres to the body at particular points only, the connexion being by means of loose cellular membrane, spaces are left which can be filled with air at the will of the *Nycteris*, through the cheek pouches, which are perforated at the bottom so as to communicate with those spaces. When the *Nycteris* wishes to inflate its skin, it draws in its breath, closes its nostrils, and transmits the air through the perforations of the cheek pouches to the subcutaneous spaces, and the air is prevented from returning by the action of a sphincter, which closes those openings, and by valves of considerable size on the neck and back.

Reproduction.—The male organs nearly approach those of the quadrumana and man in many respects. The principal organ is pendulous, but it is furnished with a small bone. The testicles are situated in the abdomen, excepting in the breeding season, when they descend and are placed on each side of the vent, and the epididymis lies behind them on either side of the insertion of the tail. There are *vesiculæ seminales*, a *prostate gland*, and *Cowper's glands*.

There is no great peculiarity in the female organs. The two teats are placed on the breast as in man and in the quadrumana. As for those so-called teats, discovered in the groin of the *Rhinolophi* by Montagu and Geoffroy, Kuhl could discover no trace of mammary glands in them.

Geographical Distribution.—The cheiroptera are widely spread over the globe. They are to be found in the Old and New World and in New Holland. A tolerably temperate climate seems necessary for them, and the greatest development of the form takes places in warm countries. Dr. Richardson (*Fauna Boreali-Americana*) notices two species, *Vespertilio pruinosus* (Say) caught at Cumberland House, on the Saskatchewan in lat. 54, and *Vespertilio subulatus* (Say) which the Dr. observes is the most common species near the eastern base of the Rocky Mountains on the upper branches of the Saskatchewan and Peace rivers.

Habits.—Generally speaking they remain in concealment during the day in caverns, ruinous buildings, hollow trees, and such hiding places, and flit forth at twilight or sunset to take their prey. White, in his 'Selborne,' thus describes the mode of feeding of a tame bat: 'It would take flies out of a person's hand; if you gave it anything to eat it brought its wings round before the mouth, hovering and hiding its head, in the manner of birds of prey when they feed. The adroitness it showed in shearing off the wings of flies, which were always rejected, was worthy of observation and pleased me much. Insects seemed to be most acceptable, though it did not refuse raw flesh when offered; so that the notion that bats go down chimneys and gnaw men's bacon, seems no improbable story. While I amused myself with this wonderful quadruped I saw it several times confute the vulgar opinion, that bats, when down on a flat surface, cannot get on the wing again, by rising with great ease from the floor. It ran, I observed, with more dispatch than I was aware of, but in a most ridiculous and grotesque manner.' The large-eared bats, collected by Carlise, refused, according to Shaw, every species of food for four days, as did a large number which were afterwards caught and preserved in a dark box, for above a week. During the day-time they were extremely desirous of retirement and darkness; and, while confined to the box, never moved or endeavoured to get out the whole day; and when spread on the carpet they commonly rested some minutes, and then, beginning to look about, crawled slowly to a dark corner or crevice. At sunset the scene was quite changed: every one then endeavoured to scratch its way out of the box; a continual chirping was kept up, and no sooner was the lid of their prison opened than each was active to escape; either flying away immediately, or running nimbly to a convenient place for taking wing. When these bats were first collected, several of the females had young ones clinging to their breasts in the act of sucking. One of them flew with perfect ease, though two little ones were thus attached to her, which weighed nearly as much as the parent. All the young were devoid of down, and of a black colour. But one of the most interesting and detailed accounts of the habits of these animals is to be found in the statement made by Mr. George Daniell to the Zoological Society of London on the 11th November, 1834, and we accordingly give it from the 'Proceedings' of that society. The bats consisted of two species, the *Pipistrelle* (*Vespertilio Pipistrellus* of Geoffroy) and the *Noctule* (*Vespertilio Noctula* of Schreber). Mr. Daniell stated that in July, 1833, he received five specimens, all pregnant females, from Elvetham in Hampshire. Many more were congregated together with them in the ruins of the barn in which they were taken, but all the rest escaped. They had been kept in a tin powder canister for several days, and on being turned loose into a common packing case, with a few strips of deal nailed over it to form a cage, they exhibited much activity, progressing rapidly along the bottom of the box, ascending by the bars to the top, and then throwing themselves off as if endeavouring to fly. They ate flies when offered to them, seizing them with the greatest eagerness, and devouring them greedily, all of them congregating together at the end of the box at which they were fed, and crawling over, snapping at, and biting each other, at the same time uttering a grating kind of squeak. Cooked meat was next presented to them, and rejected; but raw beef was eaten by them with avidity, and with an evident preference for such pieces as had been moistened with water. This answered a double purpose; the weather being warm numbers of the blue-bottle flies (*musca vomitoria* of Linnæus) were attracted to the meat; and on approaching within range of the bats' wings were struck down by their action, the animal itself falling at the same moment with all its membranes expanded, and cowering over the prostrate fly, with its head thrust under in order to secure its prey. When the head was again drawn forth the membranes were immediately closed, and the fly was observed to be almost invariably taken by the head. Mastication appeared to be a laboured operation, consisting of a succession of eager bites and snaps, and the sucking process (if it may be so termed), by which the insect was drawn into the mouth, being much assisted by the looseness of the lips. Several minutes were employed in devouring a large fly. In the first instance the flies were eaten entire, but Mr. Daniell afterwards observed detached wings in the bottom of the box. These, however, he never saw rejected, and he is inclined to think that they are generally swallowed. A slice of beef attached to the side of the box was found not only to save trouble in feeding, but also by attracting the flies to afford good sport in observing the animals obtain their food. Their olfactory nerves appear to be very acutely sensible. When hanging by their posterior extremities, and attached to one of the bars in front of the cage, a small piece of beef placed at a little distance from their noses would remain unnoticed; but when a fly was placed in the same situation they would instantly begin snapping after it. The beef they would eat when hungry; but they never refused a fly. In the day-time they sometimes clustered together in a corner; but towards evening they became very lively, and gave rapid utterance to their harsh grating notes. One of them died on the fifth day after they came into Mr. Daniell's possession; two on the fourteenth; the fourth survived until the eighteenth; and the fifth until the nineteenth day. Each was found to contain a single *fœtus*.

---

[*] Shaw says that, from Mr. Jurine's anatomical observations on these animals, it appears that a very large proportion of nerves is expanded on the upper jaw, the muzzle, and the organ of hearing: and thus appeared to him, in a great degree, to account for the extraordinary faculty above described.

On the 16th May, 1834, Mr. Daniell procured from Hertfordshire five specimens of *Vespertilio noctula*, four females and one male. The latter was exceedingly restless and savage, biting the females, and breaking his teeth against the wires of the cage, in his attempts to escape from his place of confinement. He rejected food and died on the 18th. Up to this time the remaining four continued sulky; but towards evening they ate a few small pieces of raw beef, in preference to flies, beetles, or gentles, all of which were offered to them: only one of them, however, fed kindly. On the 20th one died, and on the 22nd two others, each of which was found to be pregnant with a single *fœtus*. The survivor was tried with a variety of food, and, evincing a decided preference for the hearts, livers, &c., of fowls, was fed constantly upon them for a month. In the course of this time large flies were frequently offered to her, but they were always rejected, although one or two *May chafers*, *Melolontha vulgaris*, were partially eaten. In taking the food the wings were not thrown forward as in the *Pipistrelle*, and the food was seized with an action similar to that of a dog. The water that drained from the food was lapped, but the head was not raised in drinking, as Mr. Daniell had observed it to be in the Pipistrelle. The animal took considerable pains in cleaning herself, using the posterior extremities as a comb, parting the hair on either side from head to tail, and forming a straight line along the middle of the back. The membrane of the wings was cleaned by forcing the nose through the folds and thereby expanding them. Up to the 20th June the animal fed freely, and at times voraciously, remaining during the day suspended by the posterior extremities at the top of the cage, and coming down in the evening to its food: the quantity eaten sometimes exceeded half an ounce, although the weight of the animal itself was not more than ten drachms. On the 23rd Mr. Daniell, observing her to be very restless, was induced to watch her proceedings. The uneasiness was continued for upwards of an hour, the animal remaining all this time in her usual attitude suspended by the posterior extremities; on a sudden she reversed her position, and attached herself by her anterior limbs to a cross wire of the cage, stretching her hind legs to their utmost extent, curving the tail upwards, and expanding the interfemoral membrane so as to form a perfect nest-like cavity for the reception of the young. In a few moments the snout of the young one made its appearance, and in about five minutes the whole of its head was protruded. The female then struggled considerably until the extremities of the radii had passed, after which the young one by means of a lateral motion of its fore limbs relieved itself. It was born on its back, perfectly destitute of hair, and blind; and was attached by an umbilical cord of about two inches in length. The female then licked it clean, turning it over in its nest, and afterwards resuming her usual position, and placing the young in the membrane of her wing, proceeded to gnaw off the umbilical cord and eat the *placenta*. She next cleaned herself, and wrapped up the young so closely as to prevent any observation of the process of suckling. The time occupied in the birth was seventeen minutes. At the time of its birth the young was larger than a new-born mouse, and its hind legs and claws were remarkably strong and serviceable, enabling it not only to cling to its dam, but also to the deal sides of the cage. On the 24th the animal took her food in the morning, and appeared very careful of her young, shifting it occasionally from side to side to suckle it, and folding it in the membranes of the tail and wings. On these occasions her usual position was reversed. In the evening she was found dead, but the young was still alive, and attached to the nipple, from which it was with some difficulty removed. It took milk from a sponge, was kept carefully wrapped up in flannel, and survived eight days, at the end of which period its eyes were not opened, and it had acquired very little hair. From these observations it is evident that the period of gestation in the *Noctule* exceeds thirty-eight days. We have only to add to this interesting account that the *Cheiroptera* hybernate.

SYSTEMATIC ARRANGEMENT.

Among the antients Aristotle says but little about the bat, and Pliny is considered to have placed it among the birds, none of which, he observes, with the exception of the bat, have teeth. (*Hist. Nat.* lib. xi., c. xxxvii.) Again (lib. x., c. lxi.), he notices it as the only winged animal that suckles its young, and observes on its embracing its two little ones and flying about with them*. In this arrangement he was followed by the older of the more modern naturalists; Belon, Gesner, and Aldrovandus, for instance. The former, after expressing some doubt, places it at the end of the night birds, in his *Histoire de la Nature des Oyseaux* (folio, 1555), and it occupies the same position in the small 4to (1557), with the following quatrain·

> 'La Souris Chauve est un oiseau de nuict,
> Qui point ne pond, ains ses petits enfante,
> Lesquels de laict de ses tetins sustante,
> En petit corps grande vertu reluit.'

The bat, *Attaleph* (bird of darkness), was one of the unclean animals of the Hebrews (*Deut.* xiv. 18), where it is placed among the forbidden birds.

Under the title 'Vespertilio,' the fourth and last genus of his first order, *Primates*, Linnæus arranged all the *Cheiroptera* known to him, and the number of species recorded in the twelfth edition of the *Systema Naturæ* amounts only to six. In the thirteenth edition (Gmelin's) the number of species given amounts to twenty-three. This edition was printed in 1789, and few families afford stronger evidence of the great influx of the new species within the last five and forty years than is to be found in the numbers of *Cheiroptera* which have been described within that period. Of English bats alone Jenyns enumerates sixteen species, and the general numbers have been increased more than six-fold. Cuvier made the *Cheiroptera* the first family of his third order of Mammifers, placing them next to the *Lemuridæ*, which close his second order, *Quadrumana*. Jenyns, in his 'Manual of British Vertebrate Animals,' places them under the order *Primates*, which he makes the second in his arrangement of British Mammalia, the *Feræ* being the first, and they come immediately after the shrews and the hedgehog.

---

* In the index to the Leyden edition (folio, 1548), the expression used is 'Vespertilio sola avium lacte nutrit;' but 'volucrum' is the expression in the text—both in book x., and book xi. The tenth book begins 'Sequitur natura avium,' and the bat is placed (c. lxi.), at the end of the chapters on birds; the rest of the book being occupied with general zoological observations.

D'Azara, Illiger, Geoffroy St. Hilaire, Desmarest, the Cuviers, Lesson, Bechstein, Kuhl, Leisler, Natterer, Temminck, Rüppel, and Spix, are among the most distinguished foreign writers on this family; and Pennant, Montagu, Sowerby, Gray, Horsfield, and Bell, among those of our own country. Zoologists seem generally to have agreed that the teeth should be made the great ground-work of classification in this as in other mammiferous families. Temminck, however, in his sixth *Monographie de Mammalogie*, shows that the genus *Dysopes* of Illiger is synonymous with the *Molossus* of M. Geoffroy St. Hilaire, and also with *Nyctinomus*. *Cheiromeles torquatus* of Horsfield is also regarded by Temminck as a *Dysopes*. To establish the identity of *Molossus* and *Nyctinomus* with *Dysopes*, the distinction of which rested only on the number of the incisor teeth of the jaw, Temminck shows that the character of these teeth varies according to the age of the individual, and that those of the upper jaw also vary in number, the dentary formula, with regard to the incisors, being either $\frac{2}{6}$, $\frac{2}{5}$, $\frac{2}{4}$, $\frac{2}{2}$, and even $\frac{2}{0}$. The lower incisors are displaced gradually by the development of the base of the canine teeth, and the projecting lateral points eventually perform the office of incisors, being opposed while in action on food to the incisors of the upper jaw, which are worn away by them. The author of the review on Temminck's sixth monograph*, where the latter describes the facts as they were observed by him in seven of the eleven species, thus proceeds: 'In order to show the mode of proof adopted by him, we follow him through one of the instances which he has adduced, that of the *Dysopes nasutus*, described by M. Isidore Geoffroy St. Hilaire as the *Nyctinomus Brasiliensis*. In one young individual of this species there existed in the lower jaw six incisors; in another five, three being on one side and two on the other; in a third four only; and in the upper jaw of this specimen, three incisors, with the alveolus, partly closed, of a fourth; in about thirteen other specimens, the number of incisors in the lower jaw was four; and in two full-grown individuals there were only two. The entire absence of even these has been found in *Dysopes obscurus*. Another observation will carry almost beyond the possibility of doubt the proof of the identity of *Nyctinomus* with *Molossus*. The type of the former genus, *Nyctinomus Ægyptiacus*, Geoff., possesses in its early age the four incisor teeth, which have been made to characterize the group, but loses two of them, when arrived at its full growth, and thus becomes an undisputed *Molossus*. On the importance of these remarks we need not observe. The anomalies which exist in the dentary system of the *Cheiroptera* have long been a stumbling block to zoologists, and can only be explained by a continued and extensive series of minute examinations, similar to those to which M. Temminck has subjected them. They afford an additional proof, if such were wanting, that a system founded on any one set of organs, however important, must become in some of its parts deficient and inadequate; it must degenerate into a mere artificial method, the natural one being attainable only by a well-directed study of the whole organization. Having drawn the attention of the reader to these observations, we proceed to a classification of the family, taken, in great measure, from the French authors, and adopted by Desmarest and Lesson. *Galeopithecus*, which is the type of the first tribe of *Cheiroptera*, according to Lesson, we have removed, in accordance with the opinions of other zoologists, from this family; and though the *Vespertilionidæ* may be divided into two natural sections, the insectivorous bats and the fruit-eaters, we have, in consideration of the gradual shades of form when the numerous species are brought under observation, followed M. Lesson's arrangement, with the exception above alluded to.

VESPERTILIONIDÆ.

§ 1. Istiophori, Spix.

Bats having a membrane in form of a leaf upon the nose. Molar teeth with sharp tubercles.

1. Sub-family, *Phyllostomatina*.

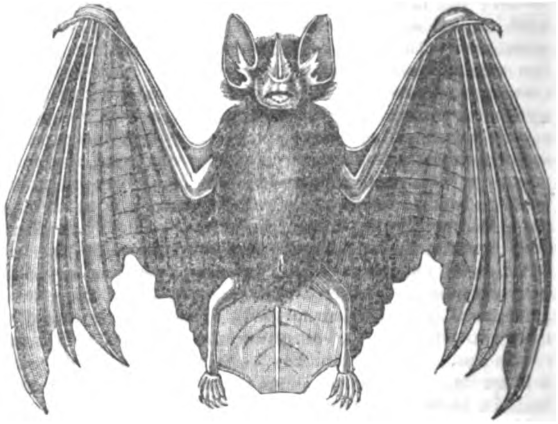
Nose-leaf simple, solitary or unequal, the forefinger composed of two joints.

Genera, Phyllostoma, Geoff.

Four incisors above and the same number below. Canine teeth very strong. Nose supporting two nasal crests, one [illegible] the other like a horseshoe. Ears large. Internal *oreillon* dentelated. Tongue bristled with papillæ. Tail variable in length, sometimes none. Dentary formula: Incisors $\frac{4}{4}$, canines $\frac{1-1}{1-1}$, molars $\frac{5-5}{5-5} = 32$.

a. Tail shorter than the interfemoral membrane.

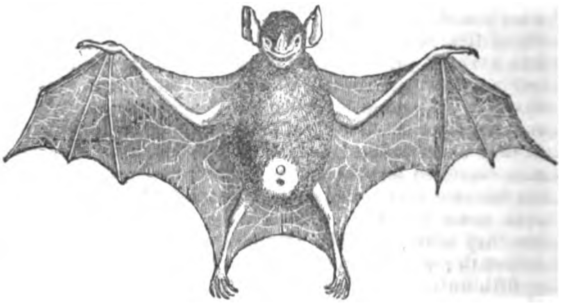
Example. *Phyllostoma crenulatum*. The borders of the nasal leaf are dentelated, the end of the tail free. Locality unknown.



[Phyllostoma crenulatum.]

b. No tail.

Example. *Phyllostoma perspicillatum*, Geoff. *Vespertilio perspicillatus*, Linn.



[Phyllostoma perspicillatum.]

Vampirus, Geoff. and F. Cuvier.

The same character as in the *Phyllostomata*, with the exception of the dental formula, which is as follows: incisors $\frac{4}{4}$, canines $\frac{1-1}{1-1}$, molars $\frac{5-5}{6-6} = 34$.

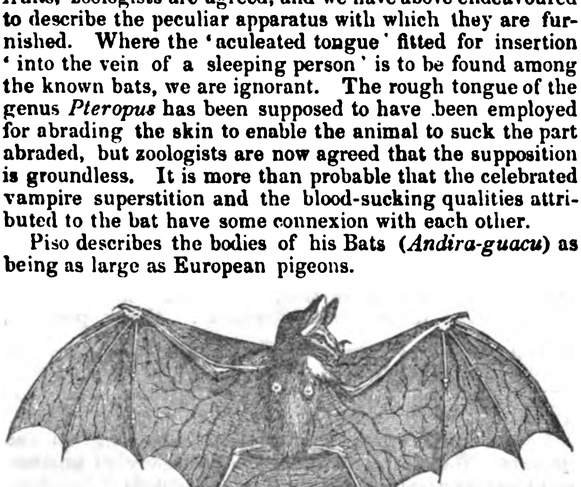
[Teeth of Vampirus Spectrum.]

Example. *Vampirus spectrum*. This is the celebrated Vampire Bat of which so many bloodthirsty stories have been told; the *Phyllostoma spectrum* of some authors, *Vampirus sanguisuga* of others, the *Andira-guacu* of Piso, and the *Vespertilio spectrum* of Linnæus. The nose-leaf is entire, higher than it is wide, although it becomes widened at the base. The following is Piso's account of its habits. 'They seek out every kind of animal and suck their blood. But in Maranhan (Maranham) there is a certain kind of bats which approach by night the naked feet of men, and wound them with their *rostrum*, for the sake of sucking human blood. The bite is so slight and subtle that the wounded do not feel it before the bed covered with blood gives token of the wound. So great a quantity of blood flows from the envenomed bite that it can only be stopped with difficulty, and the peril is imminent unless a cure by the prescribed remedies be effected. The inhabitants first wash these wounds with hot sea-water, and afterwards apply hot ashes, or even cautery, if the blood be not stopped.' Captain Stedman, who states that he was bitten, thus describes the operation: 'Knowing by instinct that the person they intend to attack is in a sound slumber, they generally alight near the feet, where, while the creature continues fanning with its enormous wings, which keeps one cool, he bites a piece out of the tip of the great toe, so very small indeed that the head of a pin could be scarcely received into the wound, which is consequently not painful; yet through this orifice he continues to suck the blood, until he is obliged to disgorge. He then begins again, and thus continues sucking and disgorging till he is scarcely able to fly; and the sufferer has often been known to sleep from time into eternity. Cattle they generally bite in the ear, but always in places where the blood flows spontaneously. Having applied tobacco ashes as the best remedy, and washed the gore from myself and my hammock, I observed several small heaps of congealed blood all round the place where I had lain, upon the ground, on examining which, the surgeon judged that I had lost at least twelve or fourteen ounces during the night.' This is sufficiently circumstantial, and the narrative is assisted by Mr. Wood, who quotes the passage in his *Zoography*, and who informs us 'that it is said to perform the operation by inserting its aculeated tongue into the vein of a sleeping person with so much dexterity as not to be felt; at the same time fanning the air with its large wings, and thus producing a sensation so delightfully cool that the sleep is rendered still more profound, and the unfortunate person reduced almost to death before he awakes.' And the same author further informs us that 'there is reason to believe that this thirst after blood is not confined to the bats of one continent, nor to one species, since at Java they seldom fail to attack those persons who lie with their feet uncovered.' The same sort of stories are to be found in most books of Natural History up to a late period. Wood's work was published in 1807, and the tales are continued in Bewick in the edition of 1820. Cuvier, in the last edition of the *Règne Animal* (1829), says, 'They have accused this species of having caused men and beasts to perish by sucking them, but it contents itself with making very small wounds which may sometimes become envenomed by the climate.' Lesson (1827), in his notice of the genus, says, 'The single American species is celebrated by the fables with which they have accompanied its history.' Dr. Horsfield, who paid particular attention to the Javanese bats, does not say a word of their blood-thirsty propensities. That some of the *Phyllostomata* suck the blood of animals as well as the juices of succulent fruits, zoologists are agreed, and we have above endeavoured to describe the peculiar apparatus with which they are furnished. Where the 'aculeated tongue' fitted for insertion 'into the vein of a sleeping person' is to be found among the known bats, we are ignorant. The rough tongue of the genus *Pteropus* has been supposed to have been employed for abrading the skin to enable the animal to suck the part abraded, but zoologists are now agreed that the supposition is groundless. It is more than probable that the celebrated vampire superstition and the blood-sucking qualities attributed to the bat have some connexion with each other.

---

* Zool. Journ., vol. iii., p. 459.

Piso describes the bodies of his Bats (*Andira-guacu*) as being as large as European pigeons.



[Vampirus Spectrum.]

Madateus, Leach.

Characterized by four incisors in each jaw; the two intermediate upper ones are longer than the lateral; they are bifid; the lower incisors are equal, simple, and pointed. Four molar teeth in the upper and five in the lower jaw on each side. Two nasal leaves. No tail. Lips furnished with soft fringed and compressed papillæ. Tongue bifid at the point.

Example. ***Madateus Lewisii.*** **Nasal leaf suddenly** pointed; ears moderate and rounded. Fur blackish. Interfemoral membrane notched. Expansion 16 inches. Locality, Jamaica.

Glossophaga.

Four incisors in each jaw; canines moderately strong. Tongue very long, extensile, and terminated by a sort of sucker. Nose surmounted by a crest in form of a pike-head. Tail none, or variable in length. Interfemoral membrane very small, hardly any. Dental formula: incisors $\frac{4}{4}$, canines $\frac{1-1}{1-1}$, molars, $\frac{3-3}{3-3} = 24$. Locality entirely American. The extensile tongue, says Lesson, enables the species to suck the blood of animals.

Example. *Glossophaga soricina* of Geoffroy, *Vespertilio soricinus* of Pallas and Gmelin. Interfemoral membrane comparatively large. No tail. Locality, Surinam and Cayenne.

Rhinopoma, Geoff.

Two incisors in the upper jaw, four in the lower. Nose long, conical, cut square as it were at the end, and surmounted with a small leaf. Nostrils straight, transversal, and operculated. Ears large, earlet (*oreillon*) external. Tail long, enveloped at its base in the interfemoral membrane, which is cut, as it were, square, and free at the extremity. Dental formula: incisors $\frac{2}{4}$, canines $\frac{1-1}{1-1}$, molars $\frac{4-4}{5-5} = 28$. There are two species only, one African, the other American.

Example. *Rhinopoma microphylla.* This is Belon's *Chauve-souris d'Egypte.* The fur is ash-coloured, and the tail very long and slender. It is the species that abounds in the long and dreary galleries of the Egyptian Pyramids.

Artibeus, Leach.

Four incisors in each jaw, of which the upper ones are bifid, and the lower ones truncated. Two canines above and the same number below; the upper ones have an internal border at their base. Four molars above and five below on each side. Two nasal leaflets, one horizontal, the other vertical. No tail.

Example. *Artibeus Jamaicensis*, the only species known. Brown above, greyish below. Flying membranes, and ears brownish. The lips are surrounded with a regular series of warts, and the mouth is provided internally with a narrow, fimbriated, cribriform membrane. Expansion about one foot, three inches. Length from the muzzle to the extremity of the interfemoral membrane, four inches, ten lines. Dr. Horsfield calls it *Phyllostoma Jamaicense*, and says that in many particulars it agrees with *Phyllostoma planirostrum* of Spix, though it is clearly distinguishable from it.

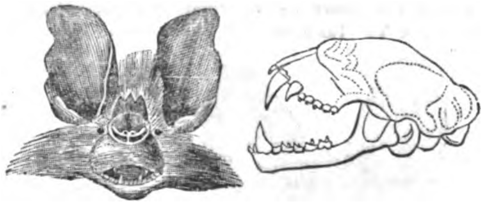
Monophyllus, Leach.

Four unequal incisors in the upper jaw, of which the two middle ones are longer than the lateral, and bifid, none in the lower jaw: Two canines in each jaw. Five molars above and six below on each side. A single straight leaf upon the nose. Tail short.

Example. *Monophyllus Redmannii.* Brown above, greyish below. Ears rounded. Nose-leaf, which is sharp, covered with small white hairs. Membranes brown. Locality, Jamaica.

2. Sub-family, *Rhinolophina.*

Nasal leaf complicated, membranous. Index with a single phalanx. Wings largely developed. Females with pectoral teats often accompanied by pubic warts simulating mamillæ.

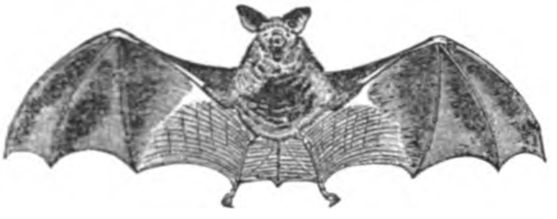


[Head and skull of Rhinolophus tridens.]

Genera, Rhinolophus, Geoff.

Nose at the bottom of a cavity bordered by a wide crest of a horseshoe shape, and surmounted by a leaf. Ears moderate, lateral, without an earlet (oreillon). Tail long, entirely enveloped by the interfemoral membrane, which is very much developed. Dental formula: incisors, $\frac{2}{4}$, canines, $\frac{1-1}{1-1}$, molars, $\frac{5-5}{6-6} = 32$. Several species.

Example. *Rhinolophus nobilis*, a rare and fine Javanese species; *Kĕblĕk* of the natives, described by Dr. Horsfield, who observes that it belongs to the second section of the genus. The nasal apparatus consists of a broad membrane stretching transversely across the nose in form of a shelf; the sides are bounded by several parallel folds, and inferiorly it constitutes a semicircular envelope, which has a short, obtusely-rounded point in the middle. Colour above, pure brown; beneath, brown variegated with grey. Fur remarkably long and silky, and supplied with a most delicate down at the base, so as to be throughout very soft to the touch. Body four inches in length. Expansion nineteen inches and a half.

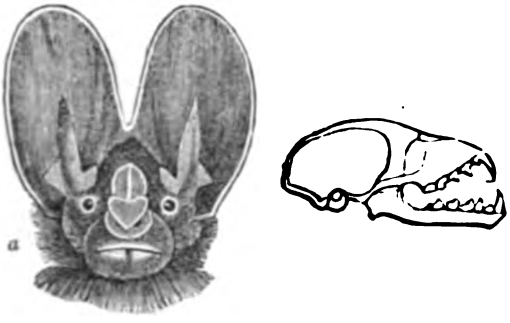


[Rhinolophus nobilis.]

Megaderma, Geoff.

Ears very much developed, and brought forward on the head. Earlet internal, wide. Three nasal crests, one vertical, one horizontal, and one inferior of a horseshoe shape. No tail. Interfemoral membrane cut square. Dental formula: incisors, $\frac{0}{4}$, canines, $\frac{1-1}{1-1}$, molars, $\frac{4-4}{5-5} = 26$.

Example. *Megaderma trifolium*. Locality, Java, where it is the *Lowo* of the natives.

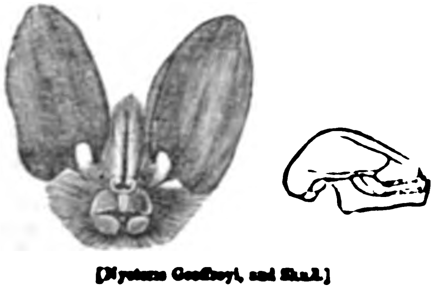


[a, Head of Megaderma Trifolium; b, Skull of Megaderma Frons.]

Nycteris, Geoff.

A very deep longitudinal *sillon* upon the *chanfrein*. Nostrils covered by a cartilaginous moveable operculum. Ears large, united at their base. Earlet external. Interfemoral membrane very large, comprehending the tail, the last vertebra of which is terminated by a bifurcated cartilage. Dental formula: incisors, $\frac{4}{6}$, canines, $\frac{1-1}{1-1}$, molars, $\frac{4-4}{5-5} = 32$.

Example. *Nycteris Geoffroyi*. Fur, grey-brown above; brighter below. Ears very large. A well-developed wart placed upon the lower lip, between two *bourrelets* having the form of a V. Locality, the Thebaïd and Senegal.

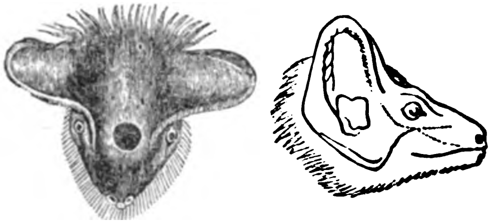


[Nycteris Geoffroyi, and Skull.]

Taphozous, Geoff.

Chanfrein with a *sillon*. Upper lip thick. Ears moderate and wide apart. Tail fine towards its point, beyond the interfemoral membrane, which is large, prolonged and angular at its external border. Dental formula: incisors, $\frac{0}{4}$, canines, $\frac{1-1}{1-1}$, molars, $\frac{5-5}{5-5} = 28$. Several species.

Example. *Taphozous Mauritianus*. Fur chestnut above, ruddy below. Earlet terminated by a sinuous border. Locality, Isle of France.



[Taphozous Mauritianus, and profile of the same.]

Mormops, Leach.

Four upper unequal incisors, of which the intermediate ones are widely notched, and four below which are equal and trifid; two canines in each jaw, the upper ones twice the length of those below, almost compressed and canaliculated before; five molars above, and six below on each side. A single nasal leaf united to the ears, which are very complicated.

Example. *Mormops Blainvillii*, the only species; and it is remarkable for the extreme elevation of its front, the excavation of its chanfrein, the lobated, crenelated form of its upper lip, and the division of the lower one into three membranous lobes, the existence on the tongue of papillæ, of which the anterior are bifid and the posterior multifid, the folding of the nasal leaf, and the division of the upper border of its ears into two lobes. Locality, Jamaica.

Nyctophilus, Leach.

Two upper, elongated, conical, pointed incisors; six lower ones equal and trifid with rounded lobes; two canines above and two below, the lower ones having a small point at the back part of their base. Four molars on each side of the jaws, with crowns furnished with pointed tubercles. Two nasal leaves, of which the posterior is the largest. Tail projecting a little beyond the interfemoral membrane.

Example. *Nyctophilus Geoffroyi*, the only species known. Fur, yellowish above. Belly, breast and throat dirty white. Ears large. Membranes brownish-black.

§ 2. Anistiophori, Spix.

Bats without any nasal appendage.

3. Sub-family, *Vespertilionina*.

Molar teeth with pointed tubercles. Wings wide and extended. A single phalanx to the forefinger (index). Head elongated. The lips simple. Tongue short. Tail long.

Genera, Vespertilio, Linn., Geoff.

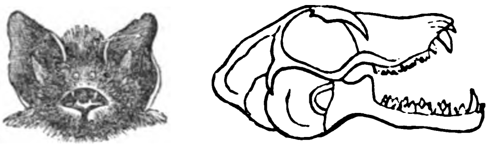
Upper incisors four, sometimes two. Lower incisors six. Muzzle very simple. Ears separated, but sometimes united at their base. Earlet internal. Tail long, entirely enveloped in the interfemoral membrane. Cheek pouches. Dental formula: incisors, $\frac{4}{6}$, canines, $\frac{1-1}{1-1}$, molars, $\frac{4-4}{5-5} = 32$.

Lesson observes that many Vespertiliones have but two incisors. The species of the genus are many in number, and their geographical distribution is very wide.

a. European species.

These are numerous. We select as an example *Vespertilio murinus* of Linnæus. This is the *Flitter-mouse*, *Flutter-mouse* and *Rear-mouse* of the English; *La Chauve-souris* of Buffon, and, according to Pennant, the *Ystlum* of the antient British; *Nattola*, *Notula*, *Sporteglione*, *Vespistrello* and *Vilpistrello* of the Italians; *Murcielago* and *Morciegalo* of the Spaniards; *Morcego* of the Portuguese; *Speckmaus* and *Fledermaus* of the Germans; *Vledermuys* of the Dutch; *Laderlap* and *Fladermus* of the Swedes; and *Flagermaus* and *Aftenbakke* of the Danes. The ears are oval, of the length of the head; the earlets falciform. The fur of the adults is ruddy-brown above, whitish-grey below; that of young individuals is grey-ash.

Locality. *Vespertilio murinus* is common in Europe. It has been supposed to exist in Asia, and even in Australia. Its haunts are caves, ruined buildings, church-towers, the roofs of houses or churches, and hollow trees, where it hybernates during the whole winter, snugly wrapped up in the wing-membranes, and suspended by the hind feet. We have given the skeleton of this species, and below will be found a head and skull of *Vespertilio pipistrellus*, another European species.



[Head and Skull of Vespertilio Pipistrellus.]

β. African species.

Example. *Vespertilio nigrita.* Adanson discovered this species at Senegal. The ears are oval, triangular, very short, one-third of the length of the head. Earlet long, and terminating in a point. Fur yellowish-brown above, and yellowish-ash below.

γ. Asiatic species.

Example. *Vespertilio pictus.* The ears are shorter than the head. oval, wider than they are high. Earlet oval-shaped. The fur is reddish, passing into bright yellow upon the back, and of a tarnished yellow on the belly. Citron-coloured rays mark the course of the fingers in the wings, which are chestnut-brown. Locality, Ceylon, where the native name is *Kirivoula.*

δ. American species.

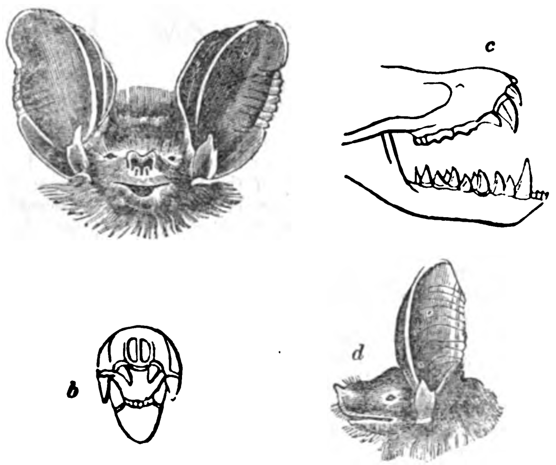
These are very numerous.

Example. *Vespertilio Naso.* This species, remarkable for the length of its nose, was first described by the Prince de Neuwied. The nasal organ is elongated in a straight line above the upper jaw, almost like a proboscis. The ears are small, and very much pointed. The fur is greyish-brown above, and yellowish-grey below. Locality, Brazil, in trees.

Plecotus, Geoff.

This genus in many of its characters agrees with *Vespertilio*, but the ears are very much developed, being larger than the head. Dental formula: incisors, $\frac{4}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{6-6} = 36$. There are several species, and the form occurs in all the four quarters of the globe.

Example. *Plecotus Timoriensis.* This species was discovered by Péron and Lesueur in the island of Timor, one of the Moluccas. The ears are ample, united at their base by a small membrane. The fur is blackish-brown above, and ash-brown below.



[Plecotus Timoriensis.]

b, front view of the teeth &c. *c*, profile of the skull; *d*, profile of the head.

The genera *Atalapha*, *Hypexodon*, and *Nycticeus* of Rafinesque, are considered doubtful by Lesson and others.

Myopteris, Geoff.

The chanfrein is united and simple. The ears are large, insulated and lateral, with an internal earlet. Tail long, half enveloped in the interfemoral membrane. Muzzle short and large. Dental formula: incisors, $\frac{2}{2}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{4-4}{5-5} = 26$.

Example. *Myopteris Daubentonii*, Geoff.; *Le Rat volant* (flying-rat) of Daubenton. The locality of this species is unknown. The upper part of the head and body is brown; beneath, the colour is dirty white, with a slight tinge of yellow.

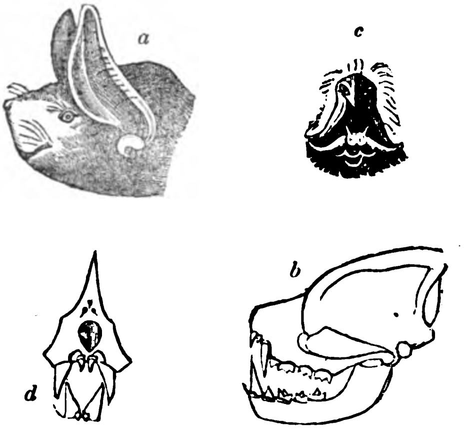
4. Sub-family, *Noctilionina.*

Molars tubercular. Wings long and straight. Two phalanges to the forefinger (index). Head short and obtuse. Lips very large. Tail recurved. The females often furnished with lateral pouches for the reception of the young in nursing.

Genera, Noctilio, Geoff.

Canines very strong. Muzzle short and swollen, and divided and studded with fleshy tubercles or warts. Nose simple, and losing itself in the lips. Ears small and lateral. Interfemoral membrane very much developed. Tail enveloped at its base. Dental formula: incisors, $\frac{4}{2}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{4-4}{5-5} = 28$.

Example. *Noctilio leporinus.* Size of a rat. Fur of a uniform reddish-yellow. This is the *Vespertilio leporinus* of Gmelin; *Noctilio unicolor* of Geoffroy. Localities, Brazil, Peru, and Paraguay.



[Noctilio Leporinus.]

a, profile of head; *b*, profile of skull; *c*, front view of muzzle; *d*, front view of teeth, &c.

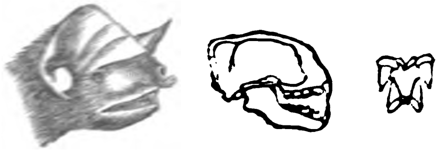
Dysopes, Illiger.

We have already noticed M. Temminck's opinion of the identity of *Molossus*, *Nyctinomus*, and *Cheiromeles* with *Dysopes*, The following is the character of the teeth, according to F. Cuvier: two incisors above and four below; two canines in each jaw; four molars on each side of the upper jaw, that is to say, two false and two normal; ten molars in the lower jaw, *viz.*, four false and six true. Type, *Dysopes Moops.* We proceed to give the definition of *Molossus*, *Cheiromeles*, and *Nyctinomus*, for the assistance of the student.

Molossus.

Head short; muzzle swollen. Ears large; earlet external. Interfemoral membrane straight, with a square termination. Tail long, enveloped at its base, and most frequently free at its extremity. Dental formula: incisors, $\frac{2}{2}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{5-5} = 28$. The geographical distribution of this form is wide: Africa, Asia, and South America possess it; but the species which are numerous occur principally in the two last-mentioned localities.

Example. *Molossus obscurus*, *Molossus fumarius* of Spix, *Dysopes obscurus* of Temminck. Size of the *Barbastelle* of Europe. Fur composed of hair of two colours, blackish-brown above, and ash-brown below. Whiskers at the corner of the lips. Length about three inches, three lines. Expansion nine inches. Localities, Brazil and Guiana.



[Head of Molossus obscurus. Skull and front teeth.]

Cheiromeles, Horsfield.

Two incisors above and two below: the upper ones large, approximate, semiconical, and acute, the lower very small and simple. Muzzle conical, sulcated, and with setiferous glandules. Ears distant, patent, with a short, semicordate, obtuse operculum. Axillary pouch ample: but the hind foot, according to Dr. Horsfield, constitutes the chief distinguishing character. The hind foot, or rather hand, 'consists of four fingers, which have the same disposition and structure as in other animals of this family, and of a distinct thumb, essentially agreeing with this member in many *Quadrumana*, and in several animals of the *Rodentia* and *Marsupialia*. It is a complete antagonist to the fingers, enables the animal to take hold of objects, and thus constitutes a perfect hand.'

Example. *Cheiromeles torquatus*, Horsfield. Researches in Java. *Molossus Cheiropus*, Auct.: *Dysopes cheiropus*, Temminck. Length, five inches and a half. Expansion nearly two feet. Localities, Siam and Western Asia.

Nyctinomus, Geoff.

Nose flat, losing itself in the lips, which are deeply slit and wrinkled. Ears large, and hanging with an external earlet. Interfemoral membrane moderate and angular. Tail long, and nearly half of it enveloped. Dental formula: incisors, $\frac{2}{4}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{5-5} = 30$. Localities: this form occurs in Africa, Asia, and South America.

Example. *Nyctinomus Ægyptiacus*, Geoff.; *Dysopes Geoffroyii*, Temminck. Reddish above and brown below. Tail slender. Interfemoral membrane enveloping only half of the tail. Locality, ruins and subterraneous places in Egypt.

Dinops, Savi.

Ears united and extended on the front. Lips pendent and plaited. Tail enveloped for half its length in the interfemoral membrane. Dental formula: incisors, $\frac{2}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{5-5} = 32$.

Example. *Dinops Cestonii*, Savi. Fur thick and soft, grey-brown, tending slightly to yellowish, but a little browner on the back. Wings black-brown. Muzzle, lips, and ears black, the latter large, rounded, and a little notched on their external border. Tail long, of a brown-black. Locality, the environs of Pisa, where Savi discovered it.

Stenoderma, Geoff.

Nose simple. Ears small, lateral, and isolated: earlet internal. Interfemoral membrane rudimentary, and bordering the legs. No tail. Dental formula: incisors, $\frac{4}{4}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{4-4}{4-4} = 28$: but it should be remembered that Cuvier only allows of two incisors in the upper jaw, instead of four, the number given by Geoffroy.

Example. *Stenoderma rufa*. Fur uniform, chestnut-red. Ears moderate, oval, and a little notched on their external border.

Celæno, Leach.

Two upper incisors pointed and simple; four lower ones contiguous and cylindrical. Two canines above and below, the upper ones largest. Four molars on each side of the jaws, the first pointed and simple, and the three last with their crowns beset with points. Third and fourth finger with three phalanges, the fifth or external with two only. Interfemoral membrane prolonged a little below the toes of the hind feet. Ears separated; earlets simple. No tail.

Example. *Celæno Brooksiana*. Back ferruginous; belly [illegible] shoulders yellowish-ferruginous. Ears pointed with the anterior border rounded and the posterior one straight. Membranes black.

Aëllo, Leach.

Two upper incisors large, compressed, bifid, and with rounded lobes. Two lower equal, trifid, with rounded lobes. Two upper canines, long, very sharp, with a small projecting point before and behind their base; the two lower smaller and less pointed. Four upper molars on each, the two first pointed and triangular, the second largest, the third bifid, and the fourth trifid externally. Third finger of the wings with four phalanges, fourth and fifth with three. Interfemoral membrane straight. Ears contiguous, short, very large; no earlet. Tail not exceeding the membrane.

Example. *Aëllo Cuvieri*. Colour ferruginous-Isabella. Wings obscure brown. Ears truncated, as it were, at the end.

Scotophilus, Leach.

Four upper incisors unequal, pointed, the intermediate ones being largest and simple, and the lateral ones bifid with equal lobes: six lower incisors indistinctly trifid. Two canines above and below, the upper ones with a small point behind their base, and the corner ones with a similar one in front. Four molars with crowns armed with points. Fourth and fifth fingers of the wings with three phalanges.

Example. *Scotophilus Kuhlii*. Fur ferruginous. Ears, nose, and wings brown.

5. Sub-family, *Pteropina*.

We now come to a numerous and widely distributed family containing some of the largest forms of the Vespertilionidæ, and subsisting principally on vegetables and fruits. It is not improbable that the fabulous harpy may have had its origin in some of these enormous bats with their well developed pectoral mammæ.

Molar teeth tuberculated and grooved longitudinally. Wings rounded. Interfemoral membrane and tail often wanting. Index with three phalanges. Head long and hairy. Females for the most part with nursing pouches.

Genera, Pteropus, Brisson. (*Roussettes* of the French.)

A small nail on the index wing-finger. Head conical. Ears short. Tail absent, or rudimentary. Interfemoral membrane very little developed.

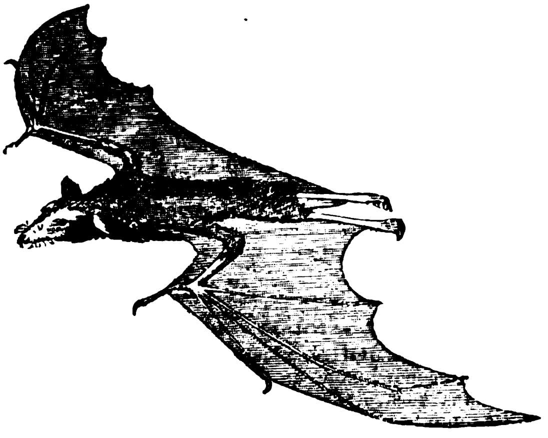
[Pteropus Dussumieri.*]

a. Tail-less.

Example. *Pteropus Javanicus*. Upper part of the neck smoky red, rest of the fur blackish, some white hairs mingled with the black ones of the back. Expansion five feet. This is the *Kalong* of the Javanese, which, according to Dr. Horsfield, is extremely abundant in the lower parts of Java, and uniformly lives in society. The more elevated districts are not visited by it. 'Numerous individuals,' continues the Doctor, 'select a large tree for their resort, and suspending themselves with the claws of their posterior extremities to the naked branches, often in companies of several hundreds, afford to a stranger a very singular spectacle. A species of Ficus, in habit resembling the Ficus religiosa of India, which is often found near the villages of the natives, affords them a very favourite retreat, and the extended branches of one of these are sometimes covered by them. They pass the greater portion of the day in sleep, hanging motionless: ranged in succession, with the head downwards, the membrane contracted about the body, and often in close contact, they have little resemblance to living beings, and by a person not accustomed to their economy are readily mistaken for a part of the tree, or for a fruit of uncommon size suspended from its branches. In general these societies preserve a perfect silence during the day: but if they are disturbed, or if a contention arises among them, they emit sharp piercing shrieks, and their awkward attempts to extricate themselves when oppressed by the light of the sun, exhibit a ludicrous spectacle. In consequence of the sharpness of their claws, their attachment is so strong, that they cannot readily leave their hold without the assistance of the expanded membrane: and if suddenly killed in the natural attitude during the day, they continue suspended after death. It is necessary therefore to oblige them to take wing by alarming them, if it be desired to obtain them during the day. Soon after sunset they gradually quit their hold, and pursue their nocturnal flight in quest of food. They direct their course, by an unerring instinct, to the forests, villages, and plantations, occasioning incalculable mischief, attacking and devouring indiscriminately every kind of fruit, from the abundant and useful cocoa-nut which surrounds the dwelling of the meanest peasantry, to the rare and most delicate productions which are cultivated with care by princes and chiefs of distinction. By the latter, as well as by the European colonists, various methods are employed to protect the orchards and gardens. Delicate fruits, such as mangos, jambus, lansas, &c., as they approach to maturity, are ingeniously secured by means of a loose net or basket, skilfully constructed of split bamboo. Without this precaution, little valuable fruit would escape the ravages of the *Kalong*. There are few situations in the lower parts of Java, in which this night wanderer is not constantly observed: as soon as the light of the sun has retired, one animal is seen to follow the other at a small but irregular distance, and this succession continues uninterrupted till darkness obstructs the view. The flight of the Kalong is slow and steady, pursued in a straight line, and capable of long continuance. The chase of the Kalong forms occasionally an amusement of the colonists and inhabitants during the moonlight nights, which in the latitude of Java are uncommonly serene. He is watched in his descent to the fruit trees, and a discharge of small shot readily brings him to the ground. By this means I frequently obtained four or five individuals in the course of an hour.'

---

* For the arrangement of teeth in Pteropus, see Carnivora.



[Pteropus Javanicus.]

β. with tails.

Example. *Pteropus stramineus*. Fur reddish yellow; tail very short. Expansion two feet. Brought from Timor by Péron and Lesueur.

γ. with wings on the back.

Cephalotes, Geoff.

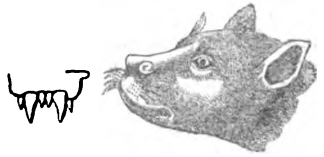
A small nail on the index in one species. Head conical; ears short; tail but little apparent. Interfemoral membrane notched. Flank-membrane springing from the mesial line of the back. Dental formula: incisors, $\frac{4}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{4-4}=32$.

Example. *Cephalotes Peronii*. Fur brown or red, and very short. No nail on the index. Wings springing from the middle of the back. Expansion two feet. Locality, Timor. N.B. Temminck thinks that the *Pteropus palliatus* of Geoffroy is the young of this species.

Harpya, Illiger.

Differing from Cephalotes in the want of lower incisors and of the last small molars in both jaws. Geoffroy thinks that the difference between the system of dentition in *Harpya* and *Cephalotes Peronii* is attributable to age only. Dental formula (Pallas): incisors, $\frac{2}{0}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{4-4}{5-5}=24$.

Example. *Harpya Pallasii*, *Cephalotes Pallasii*, Geoff. Fur consisting of scanty and soft hairs, greyish-ash above, pale white below. A nail on the index. Expansion 1 foot 11 inches. Locality, the Moluccas.



[Head of Harpya Pallasii.]

Cynopterus, F. Cuvier.

Four incisors and two rudimentary false molars in each jaw, like the Pteropi, but they entirely want the last molars. The jaws are abbreviated, and the heads much resemble those of Cephalotes.

Macroglossa, F. Cuvier.

A genus approaching very closely to *Pteropus* and formed by M. F. Cuvier for the *Lowo-assu* of the Javanese, *Pteropus minimus* of Geoffroy, *Pteropus rostratus* of Horsfield. Its character depends upon the extreme length of the head, the absence of false molars, the great development of the posterior molar and the extensile tongue. Dental formula: incisors, $\frac{4}{4}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{5-5}{6-6}=34$.

Example, *Macroglossa Horsfieldii*, *Pteropus rostratus*, Horsfield. Temminck is of opinion that *Macroglossa Kiodotes*, *Pteropus minimus*, Geoff., and *Macroglossa Horsfieldii* are identical.

δ. Wings placed extremely backwards.

On the 13th October, 1835, at a meeting of the Zoological Society, Mr. Bennett called attention to a *Pteropine Bat* which had recently been obtained from the neighbourhood of the river Gambia, and which was exhibited. He directed especial notice to two large tufts of white hairs placed upon its shoulders and forming a very conspicuous feature in its appearance. These, he remarked, might probably cover cutaneous glands destined for the preparation of a secretion fitted to defend that part of the animal in its passage through the air, or perhaps to attract the opposite sex. It could scarcely be conceived that they have any influence in increasing the buoyancy of the animal; although the backward position of the wings might seem to render necessary such a supplemental aid; their position in advance of the ordinary alar membranes gives them, in fact some resemblance to supplementary wings.

He stated that on account, chiefly, of the position of th wings so far backward as almost to seem to be placed behind the centre of gravity, he was disposed to consider the bat exhibited might be regarded as the type of a new genus, to which the name of *Epomophorus* might be given. But the genus would, he conceived, rest almost entirely on this single character, and he hesitated to propose it definitively until he had an opportunity of examining a specimen preserved in spirit, and consequently not liable to that distortion to which the individual skin exhibited might have been subjected. In one of the two other species of *Pteropi* previously obtained from the same country by Mr. Rendall, and brought under the notice of the Society on July 14th (*Pteropus Gambianus* and *Pteropus macrocephalus*), by Mr. Ogilby, the same backward position of the wings exists. In dentary characters the new species agrees with those just referred to, the only exception being in the presence of a third abnormal incisor on the left of the upper jaw.

Regarding it as a form of some interest to zoologists, Mr. Bennett stated his intention to describe it more fully in a paper which he proposed to prepare on the subject. He characterized it as the *Pteropus epomophorus*[*]. Pale brown, the colour being paler posteriorly; belly white; humeral brush (or epaulette) white and large. Total length, six inches three quarters; length of the head, two inches and a quarter. Expansion twelve inches[†].

On the 26th April, 1836, at a meeting of the Zoological Society of London, characters were read of *Vespertilionidæ* observed in the central region of Nepaul; being a communication transmitted to the Society by B. H. Hodgson, Esq., Corr. Memb. Z.S. They had already been published in the 'Journal of the Asiatic Society of Calcutta.'

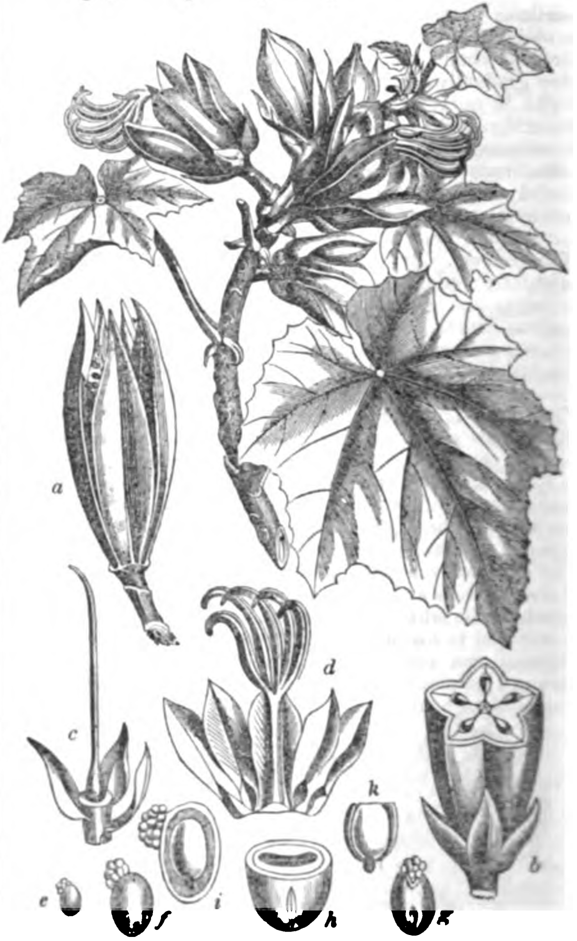
The following are the species characterized in this communication:

Rhinopholus armiger, Hodgs.
Rhin. tragatus, Ej.
Pteropus leucocephalus, Ej.
Pter. pyrivorus, Ej.
Vespertilio formosus, Ej.
Vesp. fuliginosus, Ej.
Vesp. labiatus, Ej.

Mr. Hodgson's characters of these species are accompanied by remarks on the habits of the several genera of bats in the district in which they occur.

Bones of bats of existing species were found in the cavities of the gypsum at Köstritz, mixed with the remains of other existing species, and with the bones of extinct animals.

CHEIROSTE'MON PLATANOI'DES, a most singular plant belonging to the natural order Bombaceæ, and commonly called the 'hand-tree,' in consequence of its stamens being so arranged as to present an appearance somewhat similar to that of a human hand. It is a lofty tree, with the habit of a plane, and a trunk about as thick as a man's body; its head divides into a number of close horizontal branches, which are of a brownish colour towards their extremities in consequence of the number of short fawn-coloured hairs that beset them. The leaves are heart-shaped, slightly seven-lobed, six or eight inches long, and a little toothed; they are a rich deep green on the upper side, and are covered with fawn-coloured hairs on the under side. The flowers are of a bright red, and appear at the ends of the branches; they consist of three external lanceolate brownish bracts, and a bell-shaped fleshy angular calyx, about an inch and a half deep, bright red inside, covered externally with a russet down; it is deeply divided into five lobes, and is marked on the outside at the base with five prominences, which correspond with an equal number of little pits filled with a slightly viscid whitish fluid. There is no corolla. There are five stamens combined into a central column-like tube, from the apex of which proceed five long slender sharp-pointed processes, which are all curved one way, coloured red, and look very much like what one might imagine to be the claws of a demon's hand; on their convex side these processes bear the anthers. The fruit is a large woody five-celled five-valved capsule, with from fifteen to twenty seeds in each cell. The singular form of the stamens and their large size has rendered this tree an object of curiosity and veneration in Mexico from time immemorial; the native Mexicans call it by the unpronounceable name of *Macpalxochiquauhitl*, which the Spaniards translate *Arbol de Manitas*, and the English *Hand-tree*. What made it a greater object of admiration was that in all Mexico only one tree was known, which was near the town of Toluca, about sixteen leagues west of the city of Mexico. The flowers of this plant were so constantly gathered by the Indians as objects of veneration, that the fruit never ripened, and it was not till the year 1801 that cuttings transferred to the Botanic Garden at Mexico struck root, and began to multiply this vegetable wonder. The original tree must be much more antient than the conquest of Mexico, for it has been distinctly described by the Spanish historians. The people of Toluca imagine that the tree is one and indivisible, that no other was ever created, nor any ever propagated; seeds, however, have been produced from the young plants in the Botanic Garden, Mexico, whence they may now be procured without difficulty. Plants of it were thus obtained some years since by Mr. Lambert, of Boyton House, in Wiltshire, and they are not uncommon in large collections. As many Mexican plants are hardy in this country, it has been hoped that this curious tree would prove so too; a plant of it, however, exposed to the winter against a wall in the garden of the Horticultural Society at Turnham Green, near London, perished. And perhaps it is not likely that other attempts will prove more fortunate; for, in the first place, it belongs to the natural order Bombaceæ, which consists entirely of plants impatient of cold; and, secondly, notwithstanding the belief of the Mexicans to the contrary, it is really found wild in Guatemala, where whole forests of it were observed near the city of that name by one of the pupils of Professor Cervantes. The hand-tree is said to form a very large tree, which preserves its leaves all the year round, and forms a fine shady canopy, flowering in November, December, and January. (See Hernandez, *Hist. Plant. Nov. Hisp.*, vol. ii., ed. 2, p. 531; Vetancourt, *Theatr. Mexic.*; Larreategui, *Dissert.*, June, 1795; Tilesius in *Act. Petrop.*, 5, 321, t. ix.; Humb. and Bonpl., *Pl. Æquinoct.*, i., 85.)



[Cheirostemon platanoides.]

a, fruit opened; *b*, section of young fruit, showing the disposition of the seeds; *c*, pistil and bracts; *d*, flower opened to show the tube of the stamens and the five anthers; (all these figures are about one-sixth less than the natural size; those which follow are some of the natural size, and others slightly magnified;) *e*, *f*, *g*, seeds; *h*, *i*, sections showing the situation of the embryo; *k*, the embryo, placed to show the cotyledons.

CHEKE, SIR JOHN, a learned writer of the sixteenth century, descended from an antient family in the Isle of Wight, was born at Cambridge, June 16, 1514. He was admitted into St. John's College, Cambridge, in 1531, where his early studies were chiefly directed to the Latin and Greek languages, the latter of which was then almost universally neglected. After taking his degrees in arts, he was chosen Greek lecturer of the university, and about 1540 became the first professor of that language in the university, upon King Henry VIII.'s foundation. He was highly instrumental in bringing it into repute, and directed his attention more particularly to reform and restore, what he considered, the original pronunciation of it. Cheke, while professor, was at the same time University Orator. In 15[illegible] he was incorporated M.A. at Oxford, where he also studied for a short time; and in 1544 was sent for to court, to be made joint-tutor for the Latin tongue with Sir Anthony Cooke to Prince Edward. He seems also to have had the Lady Elizabeth for some time under his care. About 1544 too he became a canon (it is believed a lay canon, for there is no proof of his having taken orders) of King Henry VIII.'s first foundation of the college in Oxford, which has been since called Christ Church; but upon the dissolution of that foundation in 1545, he was allowed a pension in the room of his canonry. When Edward VI. came to the throne he rewarded Cheke with an annuity of a hundred marks, and made him one or two favourable grants in purchase of monastic property. In 1548 he had a grant of the college of Stoke by Clare, in Suffolk, and in the year following the house and site of the priory of Spalding in Lincolnshire; but surrendered his annuity upon receiving the latter grant. The king likewise caused him, by a mandamus, to be elected provost of King's College, Cambridge. In 1550 he was made chief gentleman of the king's privy chamber, and in 1551 received the honour of knighthood. About this time he was engaged in various conferences and disputations, on the Protestant side, on the subject of the sacrament, transubstantiation, &c. In 1552 he became clerk of the council, and soon after one of the secretaries of state, and privy-councillor. This was the height of Sir John Cheke's fortunes. His zeal for the Protestant religion induced him to approve of the settlement of the crown upon Lady Jane Gray; and he acted for a very short time as secretary to her and her council after King Edward's decease. Upon Mary's accession to the throne he was committed to the Tower, and an indictment was drawn up against him: but he remained in prison, and the year following, having been stripped of his whole substance, received a pardon, and was set at liberty September 3, 1554. Foreseeing the days of persecution, he obtained a licence to travel for some time, and went to Basle, and thence to Italy At Padua he renewed his Greek studies: and afterwards, in his return from Italy, settled at Strasburg, where he was so reduced in circumstances as to be obliged to read a Greek lecture for subsistence. In the beginning of 1556 he came, by a treacherous invitation, to Brussels, though under misgivings, which were only allayed by the consultation of astrology, a pseudo-science to which Sir John Cheke was unfortunately attached, and which upon this occasion deluded him. Between Brussels and Antwerp he fell into a snare. He was seized by order of Philip II., blind-folded, thrown into a waggon, conveyed to the nearest harbour, put on board a ship under hatches, and brought again to the Tower of London. He soon found that this was on account of his religion. The desire of gaining the reconciliation of so great a man to the Church of Rome induced the queen to send not only two of her chaplains, but Dr. Feckenham, at that time dean of St. Paul's, to endeavour to convert him. The chaplains had no success with their arguments; but Feckenham's were brought into a narrower compass: he said, 'Either comply or burn.' Cheke could not withstand the dreadful alternative. On July 15, after a previous negotiation with Cardinal Pole, he wrote to the queen, and declared his readiness to obey her laws and other orders of religion. He afterwards not only made his solemn submission before the cardinal, but on the 4th of October made a public recantation before the queen, and after that before the whole court. Upon these mortifications his lands were restored to him, but upon condition of an exchange with the queen for others. The papists, by way of triumph, were not merely content with watching him: they obliged him to keep company generally with Catholics, and even to be present at the examinations and convictions of those they termed heretics. Remorse and vexation sate at last so heavy on Cheke's mind, that he pined away with shame and regret. He died September 13, 1557, at the age of forty-three, and was buried in the north chapel of the choir of the church of St. Alban, Wood Street, London. For the list of Sir John Cheke's works, we refer to the authorities whence the present notice of him has been drawn. Some of them are in very elegant Latin. One of his pieces, entitled 'The Hurt of Sedition, how grievous it is to a Commonwealth,' written on occasion of the insurrections in Devonshire and Norfolk in 1549, was reprinted by Dr. Gerard Langbaine of Queen's College, Oxford, in 1641, for the use and consideration of those who took arms against Charles I. Few of Sir John Cheke's works would suit the reading of the present day. Still he was one of the most learned men of his age, one of its greatest ornaments, and one of the revivers of polite literature in England. (Strype's *Life of Cheke*, 8vo. Lond. 1705; *Biogr. Brit.*, old edit., vol. ii. p. 1309; Bliss's edit. of Wood's *Athenæ Oxonienses*, vol. i. p. 241; Chalmers's *Biogr. Dict.*, vol. ix. p. 225.)

---

[*] Called Pteropus Whitei in the Index.

[†] Proceedings of the Zoological Society of London, 1836, part iii. p. 149.

CHELIDO'NIUM, a small Papaveraceous genus, the only species of which is a glaucous rather hairy annual, with small yellow flowers, a siliquose capsule, and orange-coloured juice, not at all uncommon in waste places in this country; it is commonly called Celandine, and possesses no useful properties worth naming.

CHE'LMON, a genus of fishes. [CHÆTODON.]

CHELMSFORD, a market-town and parish in the hundred of Chelmsford, and nearly in the centre of the county of Essex, of which it is the county town, 28 miles N.E. by E. from London, on the high road to Ipswich.

Chelmsford derives its name from its situation in the vicinity of an antient ford on the river Chelmer, near its confluence with the river Cam. In the reign of Edward the Confessor, and at the time of the Norman survey, it was in the possession of the bishops of London. But it was never a place of any importance till the reign of Henry I., when Maurice, then bishop of London, built a stone bridge over the river Cam, and diverting the road which previously passed through Writtle, made Chelmsford the great thoroughfare to Suffolk and Norfolk. From this time the town has gradually increased in importance. It consists principally of three streets, which are macadamized, and partially lighted with gas. The houses are generally well built. The inhabitants are well supplied with water from a spring, called Burge's Well, about one mile from the town. The water is conducted through pipes into a reservoir, over which is a dome supported by six Doric columns. A handsome stone bridge was erected over the Cam in the latter part of the last century, connecting the town with the hamlet of Moulsham, and replacing the old bridge built by Bishop Maurice.

The shire hall is a handsome building, fronted with Portland stone. The basement, which is rustic, supports four Ionic pillars; between the pillars are three figures in basso-rilievo, of Wisdom, Justice, and Mercy. In the upper part of the building, besides two commodious courts, are a grand-jury-room and witness-room, and an assembly-room, 86 feet by 30 feet, where public balls are held at Easter and Christmas. Over the chimney-piece of the grand-jury room is a handsome bust of Thomas Gardiner Bramston, Esq., twenty years a chairman of the quarter-sessions. The old jail, built in 1779, is now only used for debtors, and the house of correction, which adjoins it, for female convicts. A new jail has lately been erected about a mile from the town, at Springfield. It is built on the radiating principle, and is capable of accommodating 272 prisoners, although it has contained many more. During the late war two extensive barracks were erected near the town, which could accommodate 4000 men, but they have recently been pulled down. The theatre is a neat building. Races take place annually at Galley-wood Common, about two miles from the town. The market-day is Friday; and fairs are held on the 12th May and 12th November, principally for horses and cattle. The assizes for the county are held here, as well as four quarter-sessions and four petty sessions.

The population of Chelmsford in 1831 was 5435, of whom 2885 were females.

The living is a rectory in the jurisdiction of the commissary of Essex and Kent. The church is dedicated to St. Mary; the body has lately been rebuilt, and is a handsome building, in the later style of English architecture. The tower is square and embattled, and is surmounted by a lofty spire. The archdeacon holds his court in this church, and the wills and records are deposited in an office over the south porch. A new chapel is now being erected by subscription (August, 1836). There are two places of worship for Independents, one for the Society of Friends, and one for Wesleyan Methodists.

The free grammar-school was founded and endowed by Edward VI. The school, in common with those at Maldon and Brentwood, has an exhibition of 6*l.* per annum at Caius College, Cambridge. The management of the school is vested in four hereditary trustees. The school-house was rebuilt in 1782, by R. Benger, Esq., on the site of a more antient one built by Sir John Tyrrell.

Chelmsford has a charity school, for the maintenance, clothing, and education of fifty boys, founded in 1713, and one for twenty girls, founded in 1714, both supported by voluntary contributions; a Lancasterian, an infant, and a national school for children of both sexes; six alms-houses, founded by Sir Thomas Mildmay, were rebuilt in the end of the last century by William Mildmay, Esq. There are also four almshouses in Baddow-lane. (*Communication from Chelmsford.*)

CHELONA'RIUM, a genus of Coleopterous insects. [ELATERIDÆ].

CHELO'NIA (Godart), a genus of Lepidopterous insects, of the section *Nocturna* (Latreille), and family *Arctiidæ* (Leach). Before we proceed with an account of this genus, which contains two of the most conspicuous and beautiful of the British moths, it may be well briefly to state the characters of the family *Arctiidæ*, as far as the diversified habit of the species will admit. The palpi are two in number, mostly three-jointed and hairy. The antennæ have a double series of pectinations; thorax large; the apex of the body generally furnished with a tuft; wings closing so as to form an angle by their junction, or folding horizontally. The males are usually larger than the females; larvæ generally very hairy, frequently furnished with numerous tufts, those on the tail and towards the head the longer.

The genus *Chelonia* is synonymous with *Arctia* of Schrank; the latter name is generally adopted by British entomologists from its priority: the term Chelonia is open to another objection, being commonly used to designate a section of tortoises.

Arctia Caja, *the large Tiger Moth*, is very common in the South of England, but apparently less so in the North. The expanded wings measure from two and a half to three inches in width; the upper wings are of a chocolate-brown colour, with numerous irregular cream-coloured markings; the under wings are scarlet, with five or six large blue-black spots; the body is also scarlet, or pinkish above, with several transverse black bands; on the under side the ground-colour is black, with pink bands: the head and thorax are brown, separated with a red ring; the legs are red at the base, and the antennæ are white.

The caterpillar of this moth is found in great abundance near London, and is frequently seen crawling on pathways: it is covered with long black hairs, and when touched will roll itself up in a ring: it feeds upon a great variety of plants, but seems most fond of lettuce, groundsel, and chickweed. The larva is found in the spring months, and turns into a pupa about June; the pupa is enclosed in a loose web of a white colour; the moth appears in the autumn.

This species is extremely variable in its imago state; we have seen specimens in which the upper wing is nearly all white, and others in which the white is almost obliterated: the spots on the under wing vary also considerably; they sometimes run one into the other so as to form a band.

Arctia Villica, the cream-spot tiger moth, is the only other well authenticated British species; it is far less abundant than the other. The upper wings are black, with about eight large cream-coloured spots; the under wings are yellowish, spotted more or less with black, and has an irregular black fascia near the margin; the abdomen is reddish, spotted with black; the head and thorax are black; the latter has two cream-coloured spots.

The caterpillar very much resembles the one last described, but has a red head and legs of the same colour; like the last it feeds upon various plants, particularly the chickweed. The moth appears about the end of June, and is rather less than the large tiger.

CHELO'NIA (Herpetology.) [TORTOISES.]

CHELO'NIANS. [TORTOISES.]

CHELO'NOBIA. [CIRRHIPEDA.]

CHELONU'RA. [TORTOISES.]

CHELSEA, formerly a village reckoned about two miles from London, but now constituting a portion of the suburbs. It is on the north bank of the Thames, in the hundred of Ossulston, Middlesex. The parish of St. Luke, Chelsea, is stated in the returns of 1831 to contain 780 statute acres and 32,371 inhabitants.

Chelsea is on a slight eminence, about fifteen feet above the Thames. The etymology of the name has raised considerable discussion; in 'Domesday' it is written Cerechede and Chelched, and Sir Thomas More, who had a house here, wrote it Chelchith. In the 16th century it began to be written Chelsey. It was once a favourite place of resort, and many of the nobility and gentry had residences here, and there were several noted taverns and public-houses with gardens, which were much frequented in the 17th and 18th centuries.

The Royal Hospital for invalid soldiers is at Chelsea. In the reign of James I., Dr. Sutcliffe, dean of Exeter, projected a college for the study of polemical divinity, which met with the king's approbation. The foundation-stone of the building was laid on May 8th, 1609. In the charter of incorporation it is termed 'King James's College at Chelsey.' But though royally patronized, and also endowed with considerable revenues by Dr. Sutcliffe, the college never flourished. It was ultimately seized by the parliament during the civil wars, and appropriated to different purposes. Charles II. gave it to the then newly-established Royal Society; but not being adapted to their use, it was restored to the king for 1300*l.* in order that the site might be occupied by the Royal Hospital.

The architect of the Royal Hospital was Sir Christopher Wren. The foundation-stone was laid on the 16th February, 1682, by the king, who was attended by a great concourse of nobility and gentry. The building was completed in 1690, at an expense, it is stated, of 150,000*l.* It is of brick, ornamented with stone quoins, cornices, pediments, and columns. The building consists of three courts, two of which are spacious quadrangles; the third, the central one, is open on the south side next the Thames. It consists of three sides of a square, ornamented with porticos and piazzas, and has a pleasing appearance. The north front is simple in its style, and consists of a centre and wings, in a straight line, with no other ornament than a plain portico. In the centre of the hospital are the chapel and the great dining-hall.

The business of the Royal Hospital at Chelsea is managed by commissioners appointed under the great seal. The establishment consists of a governor and lieutenant-governor, with various subordinate officers. There are usually upwards of 500 invalids in the hospital, who are divided into classes, and regulated by military discipline. In addition to their provision and clothing, they receive a weekly pay, varying, according to rank and service, from 8*d.* to 3*s.* 6*d.* The out-pensioners of Chelsea hospital amounted lately to upwards of 85,000, who receive from 5*d.* to 3*s.* 6*d.* per day.

There is also in Chelsea the Royal Military Asylum. The building is on an extensive plan; the foundation-stone was laid by the Duke of York in 1801, and it was completed in 1805. It is appropriated to the support and education of children (especially orphans) of soldiers and non-commissioned officers.

The Apothecaries' Company of London have a botanical garden at Chelsea. In the centre of it is a statue, by Rysbrack, of Sir Hans Sloane, from whom the company received the freehold of the ground, the consideration paid being an annual presentation of plants to the Royal Society.

The old parish church of Chelsea not being adapted to the wants of the rapidly-increasing population, a new church was erected, which was consecrated in 1824. It is a spacious and magnificent building, in the pointed style of architecture. The old church is now the parish chapel. The parish is in the diocese of London. The average gross annual income of the rector of St. Luke's, Chelsea, is 1003*l.*; he appoints the minister of the parish chapel, whose income is 300*l.*

In the educational returns of 1835, it was stated that there were forty daily schools (exclusive of the Royal Military Asylum) in Chelsea, in several of which there were endowments for educating children gratuitously, and thirty other schools, besides several not enumerated in the return. (Lysons's *Environs of London*; Faulkner's *Chelsea*.)

CHELTENHAM, a town and parish in the hundred of Cheltenham, eastern division of Gloucestershire, 88 miles W. by N. from London, 8 miles N.E. from Gloucester, and 39½ miles N. by E. from Bath. The area of the parish is 3740 acres. The town lies in the east quarter of the parish; it is rapidly increasing, particularly N.W. and S., in which directions the limits of the parish afford ample space for its extension. Cheltenham was created a parliamentary borough under the Reform Act; the borough is co-extensive with the parish, and returns one member. The town is a polling place for the eastern division of the county.

The town of Cheltenham owes its existence to its mineral springs and its pleasant situation. The Cotswold hills form an immense amphitheatre on the N.E.; and the valley in which it lies being open on the S. and W. renders its temperature equable and agreeable. A saline spring was discovered here about the year 1716; some years afterwards it was inclosed, and invalids began to visit the place in summer; but it was not till near the end of the eighteenth century that the few houses constituting Cheltenham assumed the appearance of a town. The discovery of a number of additional springs favoured its increase. In 1811 the population of the parish, more than one-half of which was concentrated in the town, was 8325; in 1821 it was 13,396; and by 1831 it was 22,942, showing an increase of 9546 in ten years. The number of houses in 1821 was 2,550; in 1831, 4349, of which latter number 2067 were taxed at 10*l.* and upwards. The amount of assessed taxes paid by the entire parish (which includes the town) was, in 1830, 21,184*l.*

Cheltenham is entirely dependent on its visitors, who are generally either persons who have no occupation or invalids of the more affluent classes. This circumstance, and the additional one, that the town is of recent creation, will sufficiently account for the fact that as to the construction of the buildings and the general arrangement of the place, Cheltenham is a very agreeable residence. The town consists of one spacious street, about a mile in length, with several branching from it at right angles. The different places of public amusement, the pump-rooms, hotels, and lodging-houses, are rather superior to what are usually found in places of similar resort. There is a large gravelled promenade, called the Well Walk, about 600 feet in length, and 20 in breadth.

In addition to the parish church, which is a fine old building, there are four episcopal chapels. Two of these, in 1835, were held by the parish incumbent, whose gross average annual income is returned at 1170*l.*; the ministers of the other two chapels have 250*l.* each. The parish is in the diocese of Gloucester. In 1835 the number of schools, daily and Sunday, in Cheltenham was 52, of which two were charity schools. There is an hospital and some minor charities. There is a railroad from Cheltenham to Gloucester. A small rivulet called the Chilt, which has given name to the parish and hundred of Cheltenham, runs past the town, and falls into the Severn. There are a variety of detached houses, some of them very handsome, in the vicinity of Cheltenham, which add to the beauty of the surrounding country.

CHELTENHAM, WATERS OF. In all the springs which emerge from the sandy vale of Cheltenham, the sulphate of soda or chloride of sodium predominates; so that they belong to the class of saline waters. It is worthy of notice that most of the saline springs of Great Britain take their rise in the new red sandstone formation. Mr. Gairdner remarks however that those of Cheltenham rise in a stratum of blue clay abounding in iron pyrites, which reposes on the inferior oolite limestone; a circumstance which, according to him, furnishes an explanation of the well-known fact, that these mineral waters are strongest when first opened, and gradually decrease in strength until it becomes necessary to sink new wells in order to obtain water of the requisite strength. The specific gravity of the water of four of the springs belonging to Thompson's Spa was observed to be diminished, and two to be increased, between 1817 and 1820, to such a degree as to excite the surprise of chemists. The number of springs at present is fourteen, each of which presents some slight difference in the amount of the saline ingredients and their concomitants. The most important differences are owing to the presence of iron in some, occasionally accompanied with carbonic acid and sulphuretted hydrogen. Iodine in the proportion of about one grain to a gallon of the water exists in most of them, except the Pittville spring, in which however bromine is found in the proportion of one grain to six gallons of the water. Those in which no iron exists partake much of the nature of sea-water, and resemble it in effects when used internally; while those in which it is present are of a chalybeate nature, and, especially when the quantity of carbonic acid is considerable, can be borne by persons who cannot tolerate the simple saline waters, and can likewise be used for a much longer time without inducing debility. It is sometimes advisable to change from one kind to another, according to the state or progress of the patient; all which points will be regulated by physicians on the spot.

The persons most benefited by the Cheltenham waters are those who, after a long residence in hot climates, are affected with diseased liver; and also those who by indulgence in good living have weakened the stomach and intestines. The mucous accumulations which occur in the bowels of children subject to worms are best removed by a course of the pure saline waters, followed by the aërated chalybeate or the sulphureous chalybeate. Children subject to glandular enlargements derive much benefit from those which contain iodine along with iron.

CHEMISTRY, from χημεία (*chemeia*). According to Suidas (in voc. χημεία) it was 'the making of silver and gold,' or what is now more generally known by the name of alchemy. [ALCHEMY.] Suidas adds that Diocletian burnt all the antient books of the Egyptians on chemistry (as above explained), in order that the Egyptians might no longer be able to acquire wealth by the practice of this art, and thus be encouraged to resist the Romans. We may probably infer from this that chemèia is an Egyptian word; and if so, its resemblance to Cham or Chem, the genuine name of the country, is a confirmation of this supposition as to its origin. But whatever may have been the original meaning of the word, it no longer includes the imaginary process above-mentioned. Various definitions of its present meaning have been given, which do not materially differ; there is a collection of these definitions in the 'Supplement to the Encyclopædia Britannica,' vol. iii. p. 1. From these we shall select Dr. Black's, which is as follows: 'Chemistry is the study of the effects of heat and mixture, with a view of discovering their general and subordinate laws, and of improving the useful arts.' According to Dr. Thomson, 'the object of chemistry is to determine the constituents of bodies, and the laws which regulate the combinations and separations of the elementary particles of matter.' —*Inorganic Chemistry*, vol. i. p. 1.

It would be useless to attempt an early history of chemistry: indeed it has been asserted, and perhaps truly, that it sprang from delusion and superstition, and was at its commencement on a level with magic and astrology. The knowledge possessed of this science before the time of Constantine has been thus summed up by Bergman: 'Some general idea may be formed of the state of chemistry in those days, from the consideration of the several subjects of the art with which they seem to have had no acquaintance. Except the acetous, no trace can be discovered of any other acid. The mineral alkali (carbonate of soda) was known to them by the name of nitre; but of the vegetable alkali (potash) they knew little; of the volatile (ammonia) they were altogether ignorant. Of neutral salts they had the marine (common salt), and the ammoniac (muriate of ammonia). Of earthy salts, they had native alum only; and of the metallic salts, copperas and native green vitriol.'

Of earths, they seem to have distinguished the calcareous and argillaceous; and of stones, a very considerable number.

Of inflammable simple substances, they were acquainted with sulphur, expressed oils, and oils distilled *per descensum*. But they knew no other method of extracting the essential oils than by the means of the unctuous. We find no account whatever of spirit of wine or æther.

Of the seven perfect metals hitherto known, they were acquainted with all but platinum; but they were ignorant of the imperfect. Some authors, indeed, make a distinction between tin and white lead, which was perhaps zinc, bismuth, or regulus of antimony. But it is impossible to draw any certain conclusion with respect to this; when even Pliny distinguishes between hydrargyrum and argentum vivum.

Expressions, digestions, and decoctions, were almost the only operations in their chemistry. Perhaps indeed they used some varieties of elixation, evaporation, and inspissation; as likewise of crystallization, sublimation, calcination, distillation *per descensum*, fusion, eliquation, vitrification, and fermentation. From the authorities, therefore, already cited, continues Bergman, 'it may be naturally inferred, that at the period under consideration the dawn only of chemistry had made its appearance; and that it was rather a collection of unconnected and ill-founded axioms, the result of observation and remarks, than a science established upon the broad basis of an infinite variety of experiments. At this time they were in want also of the proper instruments, and unacquainted with the necessary steps by which the principles of natural bodies can be exactly separated, collected, and properly defined. They were, therefore, without those means so necessary to the evolution of truth, and the construction of a genuine system.'—*Physical and Chemical Essays*, vol. iii. p. 91.

From the seventh to the seventeenth century, or what Bergman terms the middle age, many important facts were discovered, and several products were added to the meagre list which has been given. We shall now notice the various new preparations, which include some most important instruments of analysis. It has been mentioned that up to the present period, the acetic acid was the only one known; but several new acids were now added. Basil Valentine described the process for making what he calls oleum vitrioli, a name by which it is commonly yet known, though more correctly called sulphuric acid, from green vitriol, or sulphate of iron; and Dornæus describes another process for preparing the same acid, which, on account of the form of the vessel used in making it, was called oleum sulphuris per campanam. Nitric acid was obtained by Raymond Lully from nitre; his process was much improved by Glauber, who employed, as at the present time, sulphuric acid to decompose the nitre; by this he produced the acidum nitri fumans, or Glauber's spirit of nitre; from common salt the same chemist procured by means of sulphuric acid the spiritus salis Glauberi, since called marine, muriatic, or hydrochloric acid. Aqua regia was prepared by Hollandus, by distilling a mixture of nitre and brine; this fluid was so named on account of its power of dissolving gold, the king of metals.

Several salts and some alkaline bodies were also discovered, or more perfectly known, during this period. Geber describes the process of rendering the alkali of tartar (carbonate of potash) caustic by means of lime; he takes some notice also of the carbonate of soda, and he mentions borax. Glauber described the salt which yet bears his name, the sal mirabile Glauberi, or sulphate of soda; he described also what he terms sal secretus, which is sulphate of ammonia. Raymond Lully added some important observations: he mentions the deliquescent property of potash, and the production of the volatile alkali, or ammonia, by putrefaction; and Basil Valentine notices its evolution from sal ammoniac by the fixed alkalis.

To Crollius chemistry is indebted for the preparation, or at any rate for the description, of several saline substances: thus he terms the salt obtained by saturating vitriolic acid with the alkali of tartar tartarus vitriolatus, a name not yet quite extinct; but he does not appear to have been aware that this salt, when obtained by other processes, was similar in its nature. Crollius also mentions the salt or acid of amber; and Bartholetus, sugar of milk. The digestive salt of Sylvius was also discovered by the chemist whose name it bears: it has since been named muriate of potash: its present appellation is chloride of potassium.

Of the earths in general but little was known, and even that little, Bergman remarks, was unsupported by the principles of chemistry; clay was distinguished from sand, but not by its genuine chemical characters. Except alum, few earthy salts were known. Hollandus describes chloride of calcium under the name of sal ammonia fixus.

Among the metals, antimony was described by Basil Valentine in 1490; bismuth by Agricola in 1530; and zinc by Paracelsus also in the sixteenth century. Bergman says that Schroeder describes the process of reducing arsenic in his Pharmacopœia of 1649; but Brandt first examined it with considerable accuracy in 1733. Many metallic salts were known and examined in this period. Nitrate of silver was called magisterium argenti, vel chrystalli Dianæ; when fused it was, as now, used as a caustic, and was called by Angelo Sala lapis infernalis. Crollius gave the appellation of luna cornua to chloride of silver; he mentions also mercurius dulcis, or calomel. The binoxide of mercury prepared by nitric acid, he calls Arcanum Corallinum Paracelsi; acetate of tin, sal Jovis; and deutoxide of antimony, antimonum diaphoreticum.

Basil Valentine gives an account of acetate of lead, under the name of saccharum Saturni, and mentions the butter of antimony, or chloride; and the white precipitate obtained from it by water is called mercurium vitæ by Paracelsus, and pulvis angelicus by Algarotti. That important medicine, the tartrate of potash and antimony, was first used by Mynsicht, and called tartarum emeticum. Basil Valentine and Paracelsus observed, that muriate of ammonia combined and sublimed with some metallic oxides, producing in the case of iron a compound originally called flores martiales. It has been already noticed, that the sulphates of iron and copper were known by the names of green and blue vitriol, and their nature was understood; in this period the white vitriol, or sulphate of zinc, was made, though its composition was imperfectly elucidated.

That sulphur was known before the age we are now treating of has been already mentioned; but in this period Basil Valentine describes a solution of it in the fixed alkali, potash. Beguinus mentions it as dissolved in the volatile alkali, or ammonia, and Vigenerus suspected that it was composed of phlogiston and vitriolic acid. Basil Valentine mentions the sulphuric and nitric æthers, but very slightly; but Crollius has described distinctly the art of preparing the former. Thaddeus, Villanovanus, and Raymond Lully describe spirit of wine, and the last calls the strongest spirit alcohol, a name which it yet retains; he mentions the separation of the water by means of carbonate of potash, while Basil Valentine prefers lime for the same purpose. Raymond Lully described the aërated volatile alkali, or carbonate of ammonia. Aëriform bodies began to excite attention at this period. Van Helmont noticed some of the properties of what he calls gas sylvestre, or carbonic acid gas: he observes that it is invisible, but that it was fixed in bodies, and he attributes the phenomena of the Grotto del Cane to its presence.

From the middle till towards the end of the seventeenth century several learned societies were formed. The Academy del Cimento was founded at Florence in 1651, the Royal Society at London in 1660, and the Academy of Sciences at Paris in 1666: these societies greatly promoted and advanced physics and experimental chemistry. In 1700 the Prussian Academy also took its rise, on the model of that of France. Before, however, these societies existed, a curious work was published in 1630 by Jean Rey, a physician of Perigord; it is entitled *Sur la Recherche de la cause par laquelle Estain et le Plomb augmentent de poids quand on les calcine.* In this work, which excited little or no attention among his contemporaries, the author, without apparently making any experiments, but relying upon those of others, shows that the weight which metals acquire during calcination is derived from the union of air with the metal; he supposes that air is miscible with other bodies besides metals, and states that it may be expelled from water. Rey is generally considered as the person who first showed that air is fixed in bodies during calcination; but in support of this opinion he quotes Libavius, Cardan, and others, as having ascertained the increase of weight in lead by its conversion into a calx.

Newton himself contributed some new and general ideas on chemical phenomena to the Royal Society; he observes that sugar dissolves in water, alkalis unite with acids, metals dissolve in acids, and he inquires whether these effects are not occasioned by an attraction between their particles. Copper dissolved in aquafortis is thrown down by iron. Is not this, he inquires, because the particles of the iron have a stronger attraction for the particles of the acid than those of copper; and do not different bodies attract each other with different degrees of force?

The principal and early chemical investigators of the Royal Society were Boyle, Hooke, and Slare. The first of these was the greatest chemist and one of the most active experimenters of his age; to him the science is indebted for the introduction of tests, or re-agents, for detecting the presence of other bodies; he overturned the idea which was then commonly entertained, that the results of the operation of fire were the real elements of things. Respecting inflammable bodies, acids, alkalis, and combination, he ascertained several important facts. The air pump, which had been invented by Otto von Guericke of Magdeburg, was improved by Boyle and Hooke, and rendered an important instrument in chemical investigations respecting air they concluded, also, that air was absolutely necessary to respiration and combustion, and that a portion only of the atmosphere was employed in these processes. Hooke, indeed, arrived at the sagacious conclusion, that the part of the air necessary to the above-named processes is the same as that contained in nitre, and that during the chemical process of combustion this matter combines with the burning body.

In 1674, Mayow of Oxford published his tracts on various philosophical subjects. He seems to have been struck with the analogy subsisting between the phenomena of respiration and combustion; many of his conclusions were correct, though some of them were erroneous. He burned a candle under a bell glass, and found the residual air so deteriorated as to be incapable of continuing combustion; he then caused a mouse to breathe a similar quantity of air, and the necessity of its renewal was soon apparent; after this, he put a mouse and a candle together under the same glass vessel, and he found that it lived only half as long as it had existed when alone under the glass. He then reversed the order of experimenting, and endeavoured to fire combustible matter in air which had been spoiled by breathing, and finding no combustion took place, he concluded that 'the nitro-aërial particles are absorbed both by the candle and the animal.' Mayow's work contains a chapter relating to the 'mutual action of salts of a contrary kind,' or to chemical combination and decomposition. A great number of new and curious facts are described in this dissertation.

Although a certain degree of similarity is observable in the views of Boyle, Hooke, and Mayow, respecting the operations of combustion and respiration, yet hitherto no theory had been attempted on a broad basis to account for chemical phenomena. But about this period, Germany, which still continued the great school of practical chemistry, gained additional credit by the labours of Beccher, who was born at Spires in 1645; he studied metallurgy and mineralogy with great assiduity, and although he did not greatly add to the collection of chemical experiments, he improved the instruments of research, and rendered manipulation more simple. His opinions were, that the elements of bodies are air, water, and three earths, one of which is inflammable, another mercurial, and another fusible; these three earths, combined with water, he supposed to constitute a universal acid which is the basis of all other acids. He entertained several other notions which are now known to be utterly at variance with the results of experiment; his greatest merit was the contrivance of a theory by which all known facts were connected, and deduced from one general principle. This theory was adopted and considerably modified by Stahl, and was by him promulgated in so imposing a form as to be received by the chemical world almost universally for nearly a century. We shall therefore now give a brief account both of this author and his opinions, long known as the Stahlian theory.

George Ernest Stahl was born in the year 1660, at Anspach. The most important of his works is his 'Fundamenta Chymiæ Dogmaticæ et Experimentalis,' which is divided into a theoretical and practical part. The idea that the metals were earthy substances impregnated with an inflammable principle had been advanced by Albertus Magnus. Beccher maintained the existence of this principle, not only as the cause of metallization, but likewise of combustibility; and Stahl much improved this view of the subject, and supported it by many ingenious and elaborate experiments. To the peculiar principle he gave the name of phlogiston; the doctrine was called the Stahlian theory. It raised the reputation of the author to the highest degree, and placed him in the first rank of chemical philosophers.

In explaining the phlogistic or Stahlian theory, it is to be understood that Beccher and Stahl considered all combustible bodies as compounds; during combustion one of the principles is supposed to be dissipated, while the other remains. Thus when charcoal is burnt, it is entirely dissipated. Stahl therefore supposed that it was phlogiston, or the inflammable principle, nearly pure; by heating charcoal with metals which had been reduced to calces, or what were termed metallic earths, they resumed their metallic appearance and properties; therefore the metals are compounds of metallic earths and phlogiston. Again, by heating Glauber's salt, which is a compound of sulphuric acid and soda, or the fossil alkali, with charcoal, a compound of sulphur and alkali is obtained. Sulphur, therefore, was supposed to be a compound of sulphuric acid and phlogiston. Now though it had been shown by Boyle that sulphur would not burn without air, and though he had stated that sulphur was contained in the acid, and not the acid in the sulphur, yet Stahl entirely neglected, in forming his theory, the influence of air in producing the phenomena on which it was founded. The first promulgation of the theory overlooked the simple fact which had been before stated, that metals, instead of becoming lighter by being burnt, as ought to have happened, had they lost anything, actually become heavier by the operation. Those who afterwards refined upon the theory, endowed phlogiston with a principle of levity, and thus the difficulty was for a time removed, but only to be revived with redoubled force, and this difficulty, when it came to be duly appreciated, proved fatal to the theory of phlogiston.

The merits of Stahl are thus briefly stated by Sir H. Davy:—'Though misled in his general notions, few men have done more than Stahl for the progress of chemical science. His processes were, many of them, of the most beautiful and satisfactory kind: he discovered a number of properties of the caustic alkalis and metallic calces, and the nature of sulphurous acid; he reasons upon all the operations of chemistry in which the gaseous bodies are not concerned with admirable precision. He gave an axiomatic form to the science, banishing from it vague details, circumlocutions, and enigmatic descriptions, in which even Beccher had too much indulged; he laboured in the spirit of the Baconian school, multiplying instances and cautiously making inductions, and appealing in all cases to experiments, which, though not of the most refined kind, were more perfect than any which preceded them.'

Several chemists of the phlogistic school followed, who contributed to the advancement of chemical science. Caspar Neumann was born at Züllichau, in Germany, in 1682. In 1724 he was appointed professor of chemistry in the Royal College of Physic at Berlin. Dr. Lewis, in the year 1759, published a translation of his works, entitled 'The Chemical Works of Caspar Neumann, M.D.,' &c. It would perhaps be difficult to mention any very important discovery contained in this work; but there are several facts, which, as facts are always valuable, must still give it a place in the library of a chemist.

John Henry Pott was born at Halberstadt, in the year 1692, and died in 1777. On the death of Neumann, in 1737, he succeeded to the chair of practical chemistry. He was a chemist of great learning and industry. The greater part of his works were collected and translated into French in 1759. In his dissertation on bismuth and zinc, he has collected the statements of all former writers, and described their properties with minute accuracy.

In the year 1709, Andrew Sigismund Margraaf was born at Berlin: he died in 1782. He made some valuable experiments on phosphorus, and on the method of extracting it from urine; he first determined the properties of alumina, demonstrated the nature of soda, and gave an easy process for preparing pure silver from its chloride. His chemical papers, down to the year 1762, were published in Paris, 1762, in two small volumes: but they do not contain all his memoirs.

In 1630 John Kunckel was born in the duchy of Schleswig; he died in 1702. In 1678 he published a treatise on phosphorus which had been originally discovered in 1669 by Brandt, an alchemist of Hamburg; all that Kunckel knew of its properties was that it was procured from urine, &c., and from this, after some years' application, he succeeded in obtaining it. The remainder of his works, excepting a treatise on glass-making, are not of great importance.

Nicholas Lemery was born at Rouen in 1645, and died in 1715. He was not the author of any very prominent discovery, but his 'System of Chemistry' contained nearly all that was known respecting the science, and the language in which it was written was more simple than that of those who preceded him. He attempted to explain the cause of earthquakes by an experiment which showed the vivid action that occurs when large quantities of iron filings and sulphur are mixed and allowed to act upon each other.

Homberg was born in 1652, in the island of Java. His papers on chemical subjects were numerous; there are however but few of them which are likely to excite much attention in the present state of the science, nor did they greatly contribute to enlarge its boundaries. The pyrophorus known by his name was prepared by mixing human fæces and alum, and heating the mixture to redness till it became a carbonaceous powder. It has been since found that carbonaceous matter in preferable forms may be used with the alum, as honey, flour, or gum. The nature of the combustion of this pyrophorus was first explained by Davy.

Henry Louis Duhamel was born at Paris in 1700, and died in 1781. He published many papers on chemical subjects. His chief contribution to the science was that of pointing out the difference between potash and soda, which had been formerly confounded.

Peter Joseph Macquer was born at Paris in 1718, and died in 1784. He first pointed out the existence of arsenic acid and the nature of several of the salts which it forms with bases; he afterwards published some important experiments on Prussian blue, and such as tended to the discovery of the nature of its colouring ingredient. He made several experiments on platinum, though without any very beneficial results to chemistry. He was the author of a Chemical Dictionary, which has been translated into many languages.

We have mentioned most of the chemists who contributed valuable additions to the science before the introduction of pneumatic chemistry. To speak of them all would require a volume. We now therefore approach, or rather commence a most important æra in the history of chemical research and discovery. Hitherto, except what had been done by Rey, Mayow, and Boyle, the effects produced by aëriform bodies, and their relation to the phenomena of chemistry, had almost entirely escaped observation; or at any rate they had been but very slightly and imperfectly considered, as shown with respect to the increase of weight which occurs during the calcination of metals, and which was rather attributed to a principle of levity in the phlogiston lost by them, than the acquisition of weight from the air.

Dr. Hales was born 1677, and died in 1761. About 1724 he recommenced the examination of aëriform bodies which had previously engaged the above-named philosophers; he attempted to ascertain the chemical relations subsisting between air and other bodies, and to determine the circumstances under which air is absorbed or extricated by natural processes. The results which he obtained were curious and important; but, owing to a fundamental error in his ideas, he drew but few inferences which contributed to elucidate the intricate and hitherto imperfectly explored paths of the science. The idea which he entertained of one elementary principle as constituting elastic matter modified by the effluvia of fluid or solid bodies, greatly aided the formation of those more just views which later and more refined experiments have since contributed to unfold. He subjected a vast number of bodies to the action of heat, and obtained gaseous products from them; thus he found that the air which he obtained from wood was fatal to animals; from nitre he procured nearly 200 times its volume of air, and from coal one third of its weight. He found that oil of vitriol, when poured on iron filings, produced very little air, but that the addition of water occasioned its evolution in large quantity. In no case, however, were the gaseous products thus procured examined with the attention which might have been expected from the novelty of the results. He also found that when phosphorus was burnt in air, the quantity of air was diminished, and white fumes were produced; but he neither examined the residual air, nor did he inquire into the nature of the white fumes resulting from the combustion of the phosphorus.

The experiments contained in his Statical Essays, published in 1727, were made to prove the transpiration of trees, and also the force with which they imbibe moisture. These experiments are not however immediately connected with our present subject.

In 1718 Geoffroy published tables of affinity; and although the affinity has since been discovered to be modified by a variety of circumstances, yet these tables have certainly been of use.

Dr. Black, Professor of Chemistry in Edinburgh, published, in 1756, his researches on calcareous, magnesian, and alkaline substances. He showed that there existed in these substances an aëriform body, possessing chemical and physical properties, perfectly distinct from the air of the atmosphere; he proved that marble and chalk contained this body capable of an aëriform existence, and that its presence constituted the difference between them and quicklime; he showed also, that it was capable of being expelled from earthy and alkaline substances by the action of an acid, and when the air thus set free was collected and examined, he found it to possess the properties of a weak acid.

Great opposition was offered to the new and important conclusions which were promulgated by Dr. Black: thus, among others, Meyer, a German chemist, attempted to prove that limestone became caustic by combining in the fire with a peculiar substance, and not, as Dr. Black had proved, by losing aëriform matter. The loss of weight which the limestone suffered was however almost a sufficient proof of the accuracy of Dr. Black's views; and, in a few years from the date of their promulgation, the opinions of Black were universally admitted to be correct.

The existence of an elastic fluid different from that of the atmosphere, greatly excited the attention of experimentalists, and they were soon led to inquire whether others might not also exist. The various gases obtained by Hales were now regarded with different views; and, before many more years had elapsed, numerous and peculiar aëriform bodies were discovered by various processes. Dr. Black's experiments on what he termed latent heat are remarkable for their simplicity, and the precision of the inferences drawn from them.

Mr. Watt derived great advantage from these in his celebrated improvements on the steam-engine.

About the year 1765, Mr. Cavendish (who was born in 1731, and died in 1810) discovered and described the properties of inflammable air, since called hydrogen gas; and he invented an apparatus for collecting and examining elastic fluids, which, although extremely simple, has been completely set aside by the more convenient methods proposed by Dr. Priestley. He ascertained the relative densities of fixed air, inflammable air, and common air.

Having stated the general properties of hydrogen gas, he shows that different metals, when dissolved in similar portions of the same acid, afford different quantities of this gas: that zinc yielded more than iron, and iron more than tin, facts which are perfectly consistent with and explained by the doctrine of equivalents; he ascertained the exact proportions of the constituent gases of the atmosphere. His most celebrated discoveries were however those of the composition of water and nitric acid; and he first determined the freezing point of mercury.

His character, as a philosopher, is thus sketched by Sir H. Davy:—'Cavendish was possessed of a minute knowledge of most of the departments of natural philosophy: he carried into his chemical researches a delicacy and precision which have never been exceeded: possessing depth and extent of mathematical knowledge, he reasoned with the caution of a geometer upon the results of his experiments and it may be said of him, what perhaps can scarcely be said of any other person, that whatever he accomplished was perfect at the moment of its production. His processes were all of a finished nature; executed by the hand of a master, they required no correction; the accuracy and beauty of his early labours even, have remained unimpaired amidst the progress of discovery, and their merits have been illustrated by discussion, and exalted by time.'

The important discoveries of Dr. Joseph Priestley next claim attention. He was born in 1733, and died in 1804. No person ever commenced a career of discovery under circumstances less likely to insure success than Dr. Priestley. He was but imperfectly acquainted with chemical science, he had but little leisure, his apparatus was very deficient, he had frequently to invent new modes of operating, and with means which were extremely scanty. All these difficulties he surmounted with indefatigable industry and ingenuity, and to him we owe the most important discoveries which have ever been made.

Pneumatic chemistry had, to a certain extent, been studied, as already shown, by Boyle, Mayow, Hales, and especially by Black and Cavendish, when Dr. Priestley began his experiments. His first memoir was published in 1772, and was on the method of impregnating water with carbonic acid gas. This paper was the result of his accidentally living near a brew-house, in which he had made experiments on the carbonic acid evolved during fermentation. Among the gaseous products which Dr. Hales obtained was that now called nitric oxide, but he did not inquire into its properties. It was again discovered, and minutely examined by Dr. Priestley, who applied it to the purposes of eudiometry, a branch of the science which may almost be said to have originated with him, and in consequence of this discovery.

Azotic gas had undoubtedly been obtained, but was not examined by Hauksbee when he passed atmospheric air over ignited metals; Dr. Rutherford also noticed it about 1772, and to him the priority of the discovery is generally assigned. It appears however that Dr. Priestley had obtained it, and noticed its properties at least as early, and perhaps sooner, for he gives an account of it in the *Philosophical Transactions* for that year.

His greatest discovery was that of what he called dephlogisticated air, now called oxygen gas. This important accession to chemical science was made on the 1st of August, 1774. He procured it by strongly heating red oxide of mercury, formed by the action of heat and air upon the metal, and collecting the gas which was evolved from it. The consequences of this discovery would require a volume for description; it has served as the basis for all that is known respecting the nature of the atmosphere, water, acids, and alkalis; and the nature of combustion has been greatly illustrated by it.

Sulphurous acid, fluosilicic acid, muriatic acid, and ammonia were first made known in the gaseous state by Dr. Priestley; he discovered nitrous oxide gas, and first obtained carbonic oxide gas, the nature of which however he mistook. He did not discover hydrogen gas, but his experiments upon it are interesting; he pointed out the existence of carburetted hydrogen gas, though he did not make many experiments upon it.

The action of electricity on various compound gases was examined by him, and he showed that an acid is formed when sparks are passed through a confined portion of atmospheric air; this fact served as the basis of Cavendish's discovery of the composition of nitric acid. In the same way the increase of bulk which he found to take place by the action of the same agent on ammoniacal gas led Berthollet to determine the nature of it. His experiments on the amelioration of atmospheric air by the process of vegetation are highly curious, and have been repeated and confirmed by subsequent investigations. His work entitled 'Experiments and Observations on different kinds of Air' contains a vast number of experiments, from which various inferences might be drawn, which he seems, in his rapid career of discovery, himself to have overlooked: such are those just mentioned; and the composition of atmospheric air and water might be added to the list.

His additions to the means previously known for experimenting on gaseous bodies have afforded the greatest facilities to those who have followed him: such are the invention of the pneumatic trough, and the substitution of mercury for water in those gases which are soluble in the latter fluid. To conclude with the observations of Sir H. Davy: 'Chemistry owes to him some of her most important instruments of research, and many of her most useful combinations; and no single person ever discovered so many new and curious substances.'

The works of Torbern Bergman (born in 1735, died in 1784) have been collected and translated into English. The first paper which he published was in 1774, 'On the Aërial Acid,' now called carbonic acid gas. If the contents of this paper be compared with the previous one of Cavendish on the same subject, it will be seen that the latter had anticipated Bergman on many of the more important facts. No notice however is taken of Cavendish's experiments in it.

He afterwards published papers on the 'Analyses of Mineral Waters,' and though the methods which he adopted are by no means accurate, they were preferable to any which had been previously used.

He published a paper on oxalic acid, of which however the discovery is said to be due to Scheele. It will be scarcely possible to enumerate even the various papers of Bergman, and much less to give an analysis of their contents. His 'Essay on Electric Attractions' is however a work of importance, and requires a more detailed notice. The intention of the author was to point out the nature of chemical affinity, and to account for the anomalies which that complicated subject appears to present. He adopts it as a principle that chemical combination is the result of an absolute force. Berthollet attempted to show that this conclusion is erroneous, and though it must be admitted that there are various circumstances which modify the action of this power, we are not so nearly without a guide to just conclusions as the experiments and opinions of Berthollet would lead us to admit.

Bergman published tables in fifty-nine columns, in which he showed the relative attraction of bodies, or what he terms elective affinity. As the order of decomposition often varies, according as it is made in the dry way or the moist, each of the fifty-nine columns was divided into two; the first exhibiting the order of decompositions in the moist, and the second in the dry way: he also stated various cases of double decomposition. These tables are constructed upon the now well-known principle, that any substance, whether acid, alkali, or metallic oxide, being placed at the head of a column, and others under it, such substance has the greatest affinity for that next to it, and for the rest, according to the nearness of their place.

It has been already observed that Bergman's processes for analyzing mineral waters were more correct than any which had been previously adopted, and although his experiments on the analysis of precious stones are far removed from perfection, yet they possess the rudiments of the methods which are now adopted. He first proposed the analysing of minerals by combining them with the fixed alkalis, by which they were rendered partially soluble in water, and totally so either in that fluid or in an acid.

He found fulminating gold to contain ammonia, and he explains the detonation to arise from the sudden decomposition of that gaseous body.

The discoveries which next claim attention are those of Charles William Scheele, who was born at Stralsund in 1742, and died in 1786. Like Priestley, Scheele began his experiments under very unfavourable circumstances with respect to apparatus and the means of procuring it.

Scheele, observing that air was requisite to combustion, subjected it to analysis. He found that certain substances, especially what was then termed liver of sulphur, and now sulphuret of potassium, when exposed to a given bulk of air, diminished it to about four-fifths of the original quantity; he found also that the flame of burning sulphur and of hydrogen gas produced the same effect. Without any acquaintance with what Priestley had previously done, he obtained, by various processes, oxygen gas, which he termed empyreal air; and he showed that this air was absorbed by liver of sulphur; and that upon adding fresh empyreal air to that left unacted upon by it atmospheric air was reproduced.

His experiments on the nature of air were followed by some on heat and light, and he gave the name of radiant heat to that portion of it which emanates from hot bodies, and, as he found, in right lines. He observed the blackening effect which is produced by the sun's rays on chloride of silver, and that the violet rays produce this effect most speedily. He made experiments on Homberg's pyrophorus, and showed that ammonia alum is incapable of forming it. In his dissertation on manganese he made the discovery of chlorine gas, or, as he called it, dephlogisticated marine acid. His essays on fluor spar contained several valuable facts, but he committed the error of supposing that the silica which he obtained in his operations, from the retort, was formed by the combination of water and fluoric acid. He pointed out the difference between plumbago and sulphuret of molybden, and he first described the molybdic and arsenic acids, and formed a compound of the latter with oxide of copper, or arsenite of copper, which has since been extensively used as a pigment, under the name of Scheele's or mineral green. He made experiments on milk, and sugar of milk; and the acid of the sugar of milk, now called lactic acid, was noticed by him. He gave a method of obtaining citric, tartaric, gallic, and some other vegetable acids; and published essays on tungsten, æther, calomel, benzoic acid, and urinary calculi, all of which contain valuable information.

He particularly examined the colouring matter of Prussian blue, which was nearly his last contribution to chemical science. The subject was one of great difficulty, considering that it involves the agency of azote, which had not long been discovered. He treats the subject however with his usual sagacity, and having obtained what is now called prussic or hydrocyanic acid, he has stated several of its properties. Besides the discoveries which have been enumerated, it is to Scheele that we are indebted for the first knowledge of barytes and of the characters of manganese.

Antoine Laurent Lavoisier was born in Paris in 1743, and died a victim to the revolution in 1794. Although the original discoveries of Lavoisier have less merit than those of Priestley and Scheele, yet his contributions to the science are numerous and important, especially as to what regards its theory. His 'Elémens de Chimie' were published in 1789. In this work he considers heat as a subtile fluid or a material substance, which he calls caloric. He argues that the different forms of matter depend in general upon the quantity of caloric which they contain. His analysis of atmospheric air, though conducted perhaps on more philosophical principles, does not offer so great precision of results as those deducible from the very simple experiment of Priestley; but it must be admitted that they had the merit of settling the question as to the nature of the atmosphere.

Van Helmont, and after him Macquer, had employed the term gas to denote all elastic fluids which differ from atmospheric air. This word Lavoisier also adopted; and as he found that the portion of the atmosphere which supported animal life also entered into the composition of acids, he called it oxygen gas; the other constituent of the air he called, from its fatal effects upon animal life, azotic gas; by this name it is yet designated by many chemists, while others prefer that of nitrogen, derived from its forming a part of nitric acid.

Lavoisier and his coadjutors effected various improvements in chemical nomenclature, most of which remain in use at present, but some alterations and additions have been rendered necessary by the highly-cultivated state of the science. The nature of the diamond had excited the attention of the Florentine Academy as early as 1690; the subject was resumed by Lavoisier, who proved, that when air was excluded it underwent no change; on the other hand he showed, that by burning it in oxygen gas carbonic acid was formed, and hence he argued, what is indeed now generally admitted, that the diamond, in its chemical nature, is similar to common charcoal.

In adverting to the solution of metals in acids, he notices the necessity of their oxidizement previously to it, and hence he argues the probability that the alkaline earths are metallic oxides, the oxygen serving as a bond of union between them and the acids: this sagacious remark has been verified by the discoveries of Davy. In his additional observations on the combinations of oxygen, he mentions the conditions necessary for its union with different bodies; the compounds arising from the union of various combustible bodies are also treated of, and those of the acids and some other compound substances. Sir H. Davy remarks, that 'Lavoisier must be regarded as *one of* the most sagacious of the chemical philosophers of the last century; indeed, except Cavendish, there is no other inquirer who can be compared to him for precision of logic, extent of view, and sagacity of induction. His discoveries were few, but he reasoned with extraordinary correctness upon the labours of others. He introduced weight and measure, and strict accuracy of manipulation into all chemical processes. His mind was unbiassed by prejudices; his combinations were of the most philosophical nature; and in his investigations upon ponderable substances he has entered the true path of experiment with cautious steps, following just analogies, and measuring hypotheses by their simple relation to facts.'

It is, however, matter of history, and ought not to be suppressed, that Lavoisier was not content merely to employ the discoveries of others, even without acknowledgment, but that he made a distinct claim to the discovery of oxygen, which Dr. Priestley has most satisfactorily refuted, by asserting, what might have been contradicted, but which was not, that he had mentioned this gas and the mode of procuring it at the table of M. Lavoisier himself. He makes scarcely any, if any, acknowledgment of the labours of his predecessors, and his friends have claimed for him the discovery of azotic gas, previously described by Priestley and Rutherford.

Claude Louis Berthollet (born in 1748, died in 1822) was the author of more than eighty memoirs on chemical subjects. His earlier papers on sulphurous acid, ammonia, and the decomposition of nitre, were published while he was yet a believer in the phlogistic theory, which he zealously defended, but afterwards renounced. One of his most important contributions to chemistry was that of demonstrating, in 1785, the nature and properties of the elements of ammonia. About the same time he made his experiments on the dephlogisticated marine acid of Scheele, which, from experiments well calculated to give rise to the opinion, he supposed to be a compound of muriatic acid and oxygen, and it was called oxygenized muriatic acid. These views, in consequence chiefly of the experiments of Davy, have been shown to be erroneous, and this gas is now called chlorine, and is admitted to have hitherto resisted all attempts at decomposition. It was stated by Scheele, in his experiments on this gaseous body, that among other properties which it possessed, was that of destroying vegetable colouring matter. In consequence of this remark Berthollet applied it to the purpose of bleaching, in which it is now most extensively and almost universally used.

The experiments which Berthollet made on prussic acid and its compounds advanced but did not complete our knowledge respecting those bodies. In examining the properties of sulphuretted hydrogen, he observed that it possessed acid properties; it was not however by the French chemists admitted to the class of acids, because it was inconsistent with theory just adopted, that all acids must contain oxygen. hollet also discovered fulminating silver, and first employed alcohol as a solvent for obtaining potash and soda in a pure state.

In 1803 Berthollet published a work entitled 'Chemical Statics,' the object of which was to controvert the opinions of Bergman on chemical affinity; but although he pointed out some difficulties attendant upon them, they were by no means refuted. In this work Berthollet also maintained the opinion that quantity may be made to overcome the force of the chemical affinity existing between bodies. There were however several points of the argument which he neglected, or with which he was unacquainted; indeed, at the period at which he wrote, the doctrine of definite proportions had not been promulgated,—a doctrine which will explain many of the apparent anomalies that occurred to Berthollet. Indeed, in a discussion with Proust, in which the latter had decidedly the advantage, Berthollet asserted that bodies were capable of uniting with each other in all proportions. But whatever may have been the erroneous views of Berthollet in some particular cases, chemistry is greatly indebted to him for many valuable discoveries and minor details; and the application of the bleaching power of chlorine is a practical scientific improvement which has, for its extent and usefulness, scarcely been equalled, except in the construction of the steam-engine.

Louis Bernard Guyton de Morveau was born at Dijon in 1737, and died in 1816. Although the publications of this chemist were very numerous, and contributed much to the extension of the science, yet he was not the author of any very prominent discovery. His papers are scattered through the 'Dijon Mémoires,' 'Journal de Physique,' and 'Annales de Chimie.' There are however some circumstances connected with the history of chemistry, in which his participation must not be overlooked. In 1787, in conjunction with Lavoisier, Berthollet, and Fourcroy, he published a work in one volume, 8vo., entitled 'Méthode de Nomenclature Chimique,' in which the important improvements projected and subsequently adopted, are detailed. In 1801 he published a tract, 'Des Moyens de désinfecter l'Air.' For this purpose he used various acids, and especially muriatic acid; but he afterwards adopted chlorine, which is now so generally used for the same purpose. The application of these disinfectants was made in 1782, although the history of it was not given to the public till the year abovementioned He was the author of a considerable portion of the chemical articles in the 'Encyclopédie Méthodique;' and that on 'Acid' has been justly commended for its accuracy, both as to experimental and historical details.

Antoine François de Fourcroy was born at Paris in 1755, and died in 1809. This chemist was more celebrated as one of the first authors, if not the earliest, of a treatise on chemistry and as a lecturer, than as a promulgator of any very great discovery. His chemical work went through several editions, and is in general written with perspicuity and attention to the history of the science: his 'Philosophy of Chemistry' is also a work of considerable merit. As a discoverer, he is to be mentioned as having first shown that the salts of ammonia and magnesia have a tendency to form double salts; and he particularly pointed out the ammoniaco-magnesian phosphate. He ascertained that biliary calculi resemble spermaceti in their nature, and that muscular flesh is convertible into a fatty substance which he has named adipocire. He published several papers in conjunction with Vauquelin, but what belongs to each it is impossible to tell. It has been supposed that the facts were principally ascertained by Vauquelin, and the account of them written by Fourcroy: among other papers, they published one giving a method of obtaining barytes from the nitrate by heat; they discovered also the existence of phosphate of magnesia in bones, and of phosphorus in the brain and in the melts of fishes.

It has been mentioned that the analysis of precious stones had, though imperfectly, been attempted by Bergman: this department of chemistry received vast accessions from the labours of Martin Henry Klaproth, who was born at Wernigerode in 1743, and died in 1817. This chemist introduced into the art of analysis more improvements than we can even allow room to detail. The vast progress which he made in the science will be fully estimated, when it is known that at the time at which he commenced his labours the correct analysis of scarcely any minerals was known, and that he analyzed nearly two hundred with so much accuracy that his results have been generally confirmed, and the simplicity of his method of operation is greatly to be commended

In 1789 he discovered a new metal in a mineral called pechblende, to which he gave the name of uranium; and in the same year in analyzing the zircon he found a new earth, which he called zirconia, and which has since been shown by Berzelius to be a metallic oxide. In 1795 he found the same substance in the hyacinth; in this year he also found in the red schorl the same metallic oxide which Gregor had previously met with and called menachine; Klaproth named it titanium, and this appellation is now generally employed. Apparently ignorant of the fact that strontia had been previously described as a peculiar earth, he in 1793 showed the difference between it and barytes, they having been confounded in Germany up to that time. In 1798 he gave an account of tellurium as a new metal, but it had been before noticed by Müller. In 1804 he described a new substance, which he called ochroita. Berzelius and Hisinger considered it a metallic oxide, and called the metal cerium. Besides these more important contributions to science, he made many discoveries of minor importance, which may be found in his 'Analyses,' of which two volumes have been published and translated into English. Besides minerals, there will be found analyses of some mineral waters, an account of the effects produced by intense heat upon various minerals, and the details of the methods of analysis, which are extremely valuable and instructive, both as to the nature and method of employing various chemical re-agents.

M. Vauquelin was one of the most distinguished analysts of the present century. He was born in Normandy, in what year we know not: but he died in 1829. His analyses were not confined to any particular class of bodies, and he published more and perhaps included a greater variety in his operations than any other chemist; his researches included the three kingdoms of nature, but his greatest discoveries were in the mineral. In the emerald and beryl he found a new earth, to which, on account of the sweetness of the salts which it formed with acids, he gave the name of glucina; but his discovery of chromium, in the state of chromic acid, in the red lead of Siberia, was an æra in chemical history. Originally met with in a scarce and valuable mineral, it has since been found in various parts of the earth combined with iron, and in immense quantity; it is largely employed for various uses; in the state of oxide for giving a green to porcelain; in that of acid, combined with oxide of lead, it forms both a fine yellow and orange chromate, which is used in painting and calico printing. It would be in vain to attempt an analysis of Vauquelin's various papers; they are chiefly to be found in the 'Annales de Chimie,' and will amply repay perusal. He was also author of a work entitled, 'Manuel de l'Essayeur,' which he was particularly competent to write, not merely on account of his great skill, but also as being assay-master of the mint.

Mr. Smithson Tennant was born in Yorkshire in 1761, and died in 1814. In 1791 he made an experiment, which confirmed the previous statement of Lavoisier as to the composition of carbonic acid. He effected this by passing phosphorus through red-hot carbonate of lime, and he found that the phosphorus was acidified at the expense of the oxygen of the carbonic acid, and that while phosphoric acid was formed charcoal was developed. In 1796 he heated the diamond with nitrate of potash in a gold tube, and he found that the diamond, by combining with the oxygen of the nitric acid, was converted into carbonic acid, and this combined with the potash of the decomposed nitrate to form carbonate of potash. He observed in 1799 that certain limestones, on account of the carbonate of magnesia which they contain, are hurtful to vegetation; he examined the substance known by the name of emery in 1802, and showed that it is a variety of corundum; and in 1804 he discovered two new metals, viz., osmium and iridium, in the grains of native platinum.

John Gottlieb Gahn (born in 1745 in South Helsingland, died in 1818) was the pupil of Bergman. He was particularly skilled in the use of the blow-pipe; and he ascertained that bone is a compound of phosphoric acid and lime. He proved the metallic nature of manganese, and stated the properties of the metal.

The Rev. William Gregor was born in 1762, and died in 1817. In the year 1791 he discovered a peculiar substance in a black sand, found in the parish of Menaccan in Cornwall. This substance was afterwards detected by Klaproth, and by him proved to be a metallic oxide, to the metal contained in which he gave the name of titanium. In 1805 Mr. Gregor described a hydrate of alumina found in Cornwall; he analyzed the uranite, and also the arseniate of lead.

Dr. William Hyde Wollaston was born about 1767, and died in 1828. His knowledge was not confined to chemistry: he made acoustics and more particularly optics also his study. His first chemical paper on urinary calculi contained much new information on this subject; he showed that the mulberry calculus is oxalate of lime mixed with animal matter; he pointed out a new calculus, which he named cystic oxide, the nature of the triple phosphate, and of the chalk stones formed on the joints of gouty persons. He discovered two new metals in the grains of native platinum, viz., palladium and rhodium; he showed that oxalic acid and potash combine in three different proportions, forming the oxalate, binoxalate, and quadroxalate of that alkali. He pointed out the nature of some small copper-coloured crystals found in the slag of an iron furnace, proving by a series of experiments, in a paper which is a perfect model of conciseness and accuracy, that they were metallic titanium. He perfected the method of rendering platinum available for the purposes of chemistry and the chemical arts, and his 'Scale of Chemical Equivalents' more effectually elucidated and extended the doctrine of definite proportions than all that had been previously done both by theory and practice. He first showed that the evolution of voltaic electricity is dependent upon chemical action, a fact which has been since amply and ably illustrated by Faraday. His 'Reflective Goniometer' has given to crystallography all the minute accuracy which it previously stood in need of; for it showed that three substances, viz., the carbonate of iron, lime, and magnesia, which were previously supposed to crystallize in rhomboids measuring the same angles, had all different angles. His paper on the finite extent of the atmosphere is replete with curious and acute observations; and he invented some optical instruments, which we need not here particularly describe.

Humphry Davy was born at Penzance, in Cornwall, in 1778, and died in 1829. To the researches and discoveries of this justly celebrated chemist it will be impossible to do justice in the space to which we are confined. His first contributions to chemical science were published in 1799, in a work edited by Dr. Beddoes, entitled 'Contributions to Physical and Medical Knowledge.' The first paper is 'An Essay on Heat, Light, and the Combinations of Light,' and the second 'On the Generation of Phos-oxygen (oxygen gas), and on the Causes of the Colours of Organic Beings;' these, although stamped with the mark of genius, are more remarkable for the speculative than experimental nature of their contents. In 1800 he published a work, entitled 'Researches, Chemical and Philosophical; chiefly concerning Nitrous Oxide, or Dephlogisticated Nitrous Air, and its Respiration.' In this, which is a work of high merit, he details the effects produced by the respiration of nitrous oxide both on himself and others. The very high reputation which he had acquired by this work was greatly increased by his paper in the 'Philosophical Transactions' for 1807, entitled, 'On some Chemical Agencies of Electricity.' In this paper he showed that the acid and alkali which had before been observed to be developed by galvanic agency were derived from the decomposition of some previously existing salt, and were not formed by the electric action. He arrived at the conclusion, from the numerous experiments described in this paper, that all bodies possessing chemical affinity for each other are in different electrical states, and that the degree of the affinity is proportional to their intensity. By the agency of voltaic electricity he decomposed the alkalis, potash and soda, and obtained from them metallic bases, to which he gave the names of potassium and sodium; he succeeded also in separating metallic bases from lime, barytes, strontia, and lithia; he was not however equally successful in decomposing those earths which have no alkaline properties, as alumina, glucina, yttria, and zirconia, though these have since yielded to other modes of decomposition. In 1807 he also discovered boron, the base of boracic acid.

In 1811 Davy read a paper to the Royal Society, in which he showed that what was called oxymuriatic acid by Berthollet, instead of being, as he supposed, a compound of oxygen and muriatic acid, was, in fact, an undecomposed substance, and therefore must be regarded as an element, and he gave to it the name of chlorine from its green colour. These views, though at first strongly opposed by Berthollet and Dr. Murray, are now universally adopted. In the following years he contributed various important papers to the

Royal Society, and among them on the following subjects:—on a compound of chlorine and oxygen; on chloride of azote; on iodine; the combustion of the diamond; on the salts called hyperoxymuriatic; on fire-damp, and the means of preventing accidents in mines; and his invention of the safety lamp. In succeeding years he published various papers on electricity, electro-magnetism, and on a method of preventing the corrosion of copper sheathing; this plan, though based on perfectly scientific principles, failed in its object from the very unexpected cause of its being rendered foul. His last paper was in 1819, on the electricity of the torpedo.

In 1812 Davy published the first part of the 'Elements of Chemical Philosophy,' a work which was never completed. It embodied the results of his discoveries, and an account of certain views of the author up to the time in which it appeared. This work bears occasional marks of haste, yet it contains evidence of its emanating from a genius of the highest order.

In concluding this brief sketch, it is hardly necessary to remark that the discoveries alluded to in it placed their author at the head of the science which he illustrated, not merely in England but in Europe; and his fame will rest on the durable base of experimental discovery and unrivalled talent for generalization.

In giving a history of chemistry, it is impossible not to notice the doctrine of definite proportions, or the atomic theory; under which head we have entered pretty fully into the history of its discovery, and mentioned the contributors to its development, whether deceased or living. In that article the discoveries and labours of Wenzel, Dr. Higgins, Mr. Higgins, Richter, Proust, Dalton, Wollaston, Berzelius, Gay-Lussac, Dr. Prout, and Faraday, are detailed so amply as to require no further notice here.

There are still some other subjects which it is necessary to mention, though we cannot allude to all the discoveries which their respective authors have made. In 1803, Sertuerner, a German apothecary, discovered in opium the first of a new class of bodies, or the vegetable alkalis; but this discovery excited little notice, till the author published a second paper in 1816; this alkali is morphia. Since this time numerous others have been found; they are all of them very active substances, and frequently poisonous. Thus the different kinds of cinchona have yielded two alkalis, quina and cinchonia, to which their virtues are owing: these were discovered by Pelletier and Caventou, in 1820. It has been found that many of the most active vegetable substances, such as hellebore, ipecacuanha, colchicum, and many others, contain an alkali. That those alkalis should not have been sooner discovered is readily accounted for by their existing combined with acids, so as not to exhibit any alkaline properties.

In 1812, iodine, a peculiar elementary substance, was discovered by M. Courtois, of Paris. The nature of this body was made the subject of numerous experiments both by Davy and Gay-Lussac. Its discovery served the purpose of illustrating and confirming the new views of Davy as to the simple nature of chlorine.

In 1818 Berzelius discovered a peculiar inflammable elementary body, to which he gave the name of selenium. In 1824 he obtained the metallic bases of silica and zirconia; and in 1829 he found a new metal, to which he gave the name of thorium. In 1818 Stromeyer discovered cadmium, a new metal; and in the same year lithium was discovered by Arfwedson; Bussy obtained magnesium from its oxide in 1829, and in 1830 Sefstrom discovered the metal vanadium.

In 1823 Mr. Faraday showed that various gases, which had previously resisted condensation, might be rendered fluid; we particularly mention this important acquisition to chemical science, because unjustifiable attempts have been made to transfer the honour of it to Sir H. Davy. Eight compound gases were rendered fluid, but chlorine is the only elementary one which yielded to the same treatment. If our space allowed, we should be happy to give a more extended view of the important discoveries of Mr. Faraday in electro-chemical and electro-magnetical science, as well as to notice his other important contributions to chemical philosophy.

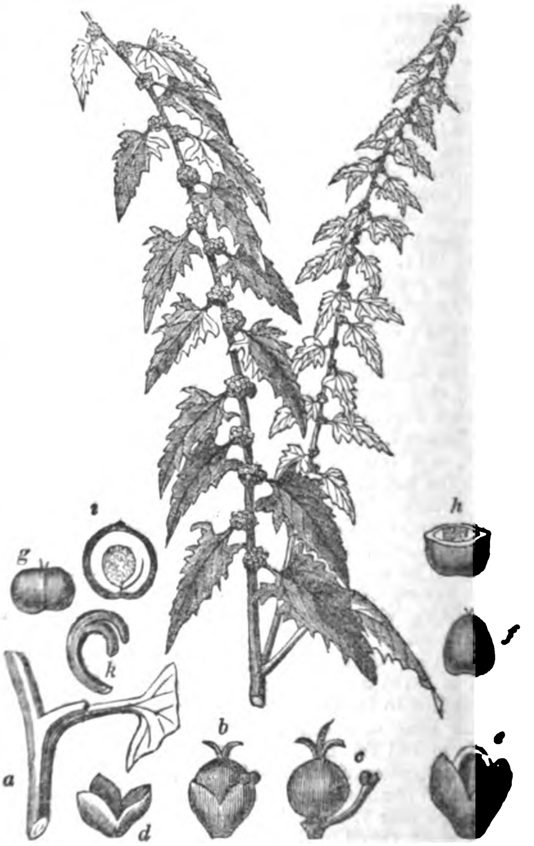
In 1826 Balard made known the new elementary body bromine, which is remarkable as being the only elementary fluid except mercury.

[illegible] cannot better conclude this slight sketch of the progress of chemistry than by adopting the words of Sir H. Davy on a similar occasion:—'To dwell more minutely upon the particular merits of the chemical philosophers of the present age will be a grateful labour for some future historian of chemistry; but for a contemporary writer it would be indelicate to assume the right of arbitrator, even where praise only can be bestowed.'

CHEMNITZ, a town in Saxony, the capital of the Erzgebirg circle, is situated at the foot of the Erzgebürge, in a plain which extends about ten miles in every direction. It is in 50° 50′ N. lat., and 17° 55′ E. long., and about 976 feet above the level of the Baltic. Chemnitz is one of the most industrious towns in Germany. In no place indeed have all the English improvements been introduced with such care and skill as in Chemnitz. The number of persons employed in weaving exceeds 2000. There are twelve manufactories for printing cotton goods, and some in which the yarn is dyed red like Turkish yarn. The woollen manufactures, which were formerly very considerable, have much decreased in the last fifty years; but in the town as well as in its neighbourhood there are many stocking manufactures. Chemnitz carries on a considerable trade, being situated where the road between Prag in Bohemia and Leipzig and that which unites Bavaria with Dresden cross one another. The town contains about 16,000 inhabitants, and is well built; the streets are spacious and mostly straight, and many of its houses look more like palaces than dwelling-houses. It is remarkable for the great cleanliness of its streets, and is lighted with lamps. The public edifices are in a good style, but none of them particularly distinguished.

CHE'NNIUM, a genus of Coleopterous insects. [PSELAPHUS.]

CHENOPODIA'CEÆ, a natural order of exogens, consisting of numerous species, used either for culinary purposes or for the manufacture of soda. They are apetalous plants, with minute green herbaceous flowers, a small number of stamens, which are opposite the segments of the calyx, and a one-celled membranous fruit, containing one single erect seed or a very small number. The leaves are soft and



[Blitum virgatum.]

a, angle of the petiole, showing the peduncle; b, flower; c, flower deprived of its calyx, showing the ovary, surmounted by three pistils; d, calyx; e, fruit imbedded in the succulent calyx; f, g, fruit separated from the calyx; h, horizontal section of fruit; i, vertical do.; k, embryo. All these figures, excepting a, magnified in various degrees.

rather succulent, without any trace of stipules. Most of them are found in the cold and temperate parts of the world. They differ from Polygonaceæ and Urticaceæ in the want of stipules, and from Amarantaceæ in their flowers not being coloured and enveloped in membranous bracts. Spinach, beet, orach, and other spinaceous plants, belong to this order, in which no deleterious species has been discovered.

CHENOPO'DIUM, the genus after which the last-mentioned order has been named, consists of weedy plants, common on dunghills and in waste places, and known by the strange names of Fat-hen (*Ch. album*), Good King Henry (*Chenopodium Bonus Henricus*), &c. They are generally insipid plants, whose leaves and young shoots may be eaten as spinach, but which have no particular merit. In this genus is however found the celebrated Quinoa of Peru (*Chenopodium Quinoa*). This plant, whose seeds are said to be of as much importance to the Peruvians as the maize, potato, and wheat, is an annual weedy species, with an appearance similar to that of garden orach, to the size of which it grows. Its flowers appear in close clusters about the ends of the branches, and are succeeded by a profusion of little black or white seeds (according to the variety) about the size of grains of millet. Its leaves are employed as spinach, and the seeds in soup or broth as rice, and in some parts of South America they are in as much use as rice in India. They are said to yield a pleasant beer when fermented. It is chiefly upon the highest land of Southern Peru, where neither barley nor rye will ripen, as, for instance, at the height of nearly 13,000 feet on the table-land of Chiquitòs, that quinoa forms the great article of agriculture; it there forms fields, the limits of which the eye can hardly reach, of a monotonous and unpleasant aspect, scarcely mixed with a single other species, and very unlike the rich and waving greenness of our standing corn. It is also extremely common about the great lake of Titicaca. The seeds are ripened in England, and may now be purchased at any of the seed-shops; but the plant can hardly be considered worth the attempt at cultivating it where any thing else will grow. (*Gardener's Magazine*, vol. x., 587; and Meyen, *Die Pflanzen Geographie*, 361.)

CHEPSTOW, a port and market-town, on the Wye (about 2½ miles from where it falls into the æstuary of the Severn), in the hundred of Caldicot, Monmouthshire, 110 miles nearly due W. from London. The parish of Chepstow contains 1020 acres; it is in the diocese of Llandaff. The population in 1831 was 3524; the average gross annual income of the incumbent of the parish was returned in 1835 at 214*l*. The parish then contained 21 daily and Sunday schools; one of which, containing 18 children, is endowed with 7*l*. per annum arising from land, and the interest of 100*l*.

The advantageous situation of Chepstow near the mouth of the Wye is supposed to have rendered it a desirable position both in Roman and Saxon times. It was formerly strongly fortified. The town is built on a hill gradually ascending from the river, and has a cheerful and lively appearance. From different points near the town the views are exceedingly beautiful—the scenery not being surpassed perhaps by any thing similar in Britain. The ruins of Chepstow Castle occupy an extensive area; the walls on one side are almost perpendicular with the cliff which overhangs the Wye; the erection of the edifice is attributed to the Normans in the eleventh century, but the architecture bears marks of a later date. In this castle Henry Marten, one of the judges of Charles I., was confined for upwards of twenty years after the Restoration, but his imprisonment does not appear to have been rigorous, though it only ended with his death. His family was permitted to live with him.

The Wye is navigable for large vessels only to Chepstow bridge, which is a massive structure of iron, erected in 1816; but barges from eighteen to thirty tons burthen can go as high as Hereford. The spring tides at Chepstow frequently rise above 50 feet.

There are no manufactories in the town or neighbourhood of Chepstow, but the town has a considerable export and import trade. It is lighted with gas, the expenses of which are defrayed by a donation from a private individual; it is also well paved, and kept clean. The gross receipt of customs' duty at Chepstow, in 1834, was 902*l*.

CHER, a river of France, from which the department which it traverses receives its name. The source of its principal branch is in the eastern extremity of the department of Creuse, a little to the south of the town of Auzance. Two other branches, which rise in the same department, form a junction with it, as it enters in its northward course the department of Allier. It continues in the same direction through the western extremity of this department, passes by Montluçon, and enters the south-east boundary of the department of Cher. Near Saint Amand it takes a N.N.W. course to Châteauneuf, and to Vierzon, where it unites with the Auron. Turning due west, it receives the Aron, passes the town of Selles, a little below which it is joined by the Sauldre and the Fouzon, and continuing its western course past St. Aignan, Montrichard, and Bléré, it falls into the Loire, a short distance below the city of Tours. This river is subject to great inundations. It has 29 locks to facilitate navigation; but from its source to St. Aignan, a distance of 48 leagues, it is serviceable only for the floating of timber. The remaining portion of 19 leagues, from St. Aignan to the Loire, is navigable for boats, which convey wood, corn, charcoal, and fodder for cattle. The whole of its course is nearly 200 miles. It supplies several kinds of edible fish. The canal du Duc de Berri runs along the Cher from Chambon, on one of its upper branches, nearly as far as Ainay. A smaller river of the same name rises in the duchy of Bar, and falls into the Meuse. (*Encyc. Méthod. Géog. Phys.*, tom. iii.; Cassini's *Map of France*; Expilly.)

CHER, a department nearly in the centre of France, comprehends that part of the antient province of Berri called Haut Berri, and a portion of Bourbonnais. Its northern boundary is formed by the department of Loiret; on the south it has the department of Allier; on the west that of Loir et Cher, and of Indre, and on the east the department of Nièvre and the river Loire. It is included between 46° 25′ and 47° 40′ N. lat., and 1° 50′ and 3° 5′ E. long. The figure formed by its boundary line is very irregular. Measured north and south its greatest length is 86 British miles, and its greatest width, east and west, 56 miles. The whole area contains 1,450,134 acres (*Diction. Universel*, by Prudhomme), or 2265 square miles. Bourges, its capital city, has a population of 18,000, and is due south of Paris, from which it is distant 125 miles in a straight line. The population of this department, in 1826, was 249,000 (Balbi, *Abrégé Géog.*), that is, between 109 and 110 to a square mile. The surface of the country is generally level, and the whole department is extremely well wooded. There are six forests that of Allogny, of Aubigny, of Bornacq, of Haute Brune, of Vierzon, and of Yvoy. They cover 150,000 hectares*, or 371,040 English acres, and furnish excellent timber for house and ship-building. Besides the Cher, there are several other considerable streams, namely, the Auron, Aron, and Sauldre, all of which belong to the basin of the Cher. In the southern and south-western parts the soil is only of a medium quality, and rushy ponds are numerous; in the northern and north-western portions are marshes, surrounded with tracts either entirely barren and sandy, or covered with furze and thistles.

In the central parts, as well as on the banks of the Auron and Cher, the land is remarkably rich, and especially on the eastern side, along the border of the Loire, where it possesses the highest productive qualities. About two-thirds of the whole surface of this department are more or less sterile and useless, and the rest exhibits the greatest fertility. Pasturage for sheep and horned cattle is abundant, and consequently great numbers are reared. The wool produced in this district is considered the best in France: the mutton also is said to be very good. Horses are generally diminutive in size. Game, poultry, and fish are abundant. All the various sorts of grain yield plentiful crops. Still, there is no perceptible improvement in agriculture; nor indeed in any other of the industrious arts. It is remarked by Malte Brun (*Géog. Univers.*, tom. iii. p. 492, 1832) that the inflexible perseverance with which the inhabitants adhere to the clumsy routine of their ancestors prevents any development of the great natural resources of this department, and accounts for the fact, that, while they have at hand a large supply of the finest wool, only a very few manufactories of inferior woollen cloths exist among them, that while they grow abundance of hemp and flax, they manufacture no linen fabric; that, with a very large home production of wax, the making of wax candles appears never to have been attempted, &c. One fact alleged as a cause of the want of improvement in agriculture, is, that the land is generally the property of great proprietors, who let the farms on short leases, and consequently destroy every incentive to exertion. Fruits of various kinds are produced in profusion, as well as the finest esculent vegetables. The vine is cultivated with considerable success, and produces the white wine which is sold in Paris under the name of Chablis. There are also small manufactures of paper, potass, porcelain, delf-ware, nut-oil, and saltpetre. The mineral productions of this department are important. Silver mines once existed; but they have ceased to be worked. Ochre is said to be obtained of a quality preferable to that of England. There are quarries of granite and marble Mention is also made of manganese, potter's clay, and gypsum; but by far the most valuable object of mining operations in this department is iron, which is found in great abundance and of very superior quality. It does not lie at a great depth, but is procured a few feet below the surface, where it appears in a granulated form, rather roundish and of a reddish colour. Numerous and extensive iron-works are established for the manufacture of iron and steel implements, nails, &c. The vigour with which this species of industry is prosecuted presents an exception to the general supineness which we have mentioned. The iron trade forms indeed, with the sale of wool, cattle, and timber, the chief source of wealth to the inhabitants. The great deficiency of means of conveyance has been partially supplied by the opening of the canal of Berri. [Cher. River.]

---

* A hectare is equal to 2·4736 English acres.

This department is divided into three arrondissements, which are subdivided into 29 cantons and 307 communes. The seat of the prefecture is at Bourges. The other considerable places are Sancerre, which stands on the highest hill in the department, and is engaged in the wine trade; population about 3000. St. Amand, on a branch of the river Cher, in a pleasant valley; population about 5000; and Vierzon, on the Auron. At Yvoy le Pré there is a glass manufactory. Henrichemont was built by Sully in honour of Hen. IV.: it has a large tannery. This department sends four members to the Chamber of Deputies: it is comprised in the 15th military division; and is within the jurisdiction of the Cour Royale of Bourges.

The department of Indre and the department of Cher form the metropolitan diocese of Bourges. (*Encyc. Méthodique, Géog. Phys.*, tom. iii.; Malte Brun; *Dict, Geog. Universelle*, 1825; Balbi, *Abrégé de Géog.*, 1833.)

CHERBOURG, a fortified city and sea-port of France, on the northern coast of the department of Manche, and one of the principal stations of the French navy. It is situated at the southern extremity of the bay and roadstead of La Manche, in lat. 49° 38′ N., and long. 1° 40′ W., opposite the Isle of Wight, 190 miles W.N.W. from Paris. Cherbourg is of great antiquity. By Froissard it is said to have been founded by Cæsar, when he invaded Britain, but by others it is denied that Cæsar ever visited this portion of Gaul. In 1418 the city was besieged by the English, to whom, after three months' resistance, it surrendered; but in 1450 it was re-taken by Charles VII., who finally expelled the English from the coasts of Normandy. Its castle, in 1680, was demolished by Louis XIV. For a detailed historical account, see the work of Expilly. It contains several capacious arsenals for marine and military stores; but that which is most remarkable at Cherbourg is the great *digue*, or breakwater, and the excavated dock for the navy. The latter, which was made by Napoleon, was opened in 1813, and is scooped out of the earth and solid rock, a little to the west of the city. It is 1000 feet in length, 770 in width, 50 in depth, and occupies about 18 acres. At low water it has a depth of 25 feet, and is capable of receiving 60 ships of the line: there is also a commodious commercial dock, distinct from that for the navy. The cost of both was about 5,000,000*l*., as it is stated in several recent English works, but it must mean francs, which would be about 200,000*l*. The breakwater is to the north of the port, and extends from east to west 4095 yards, so as to leave a passage at each end. It was commenced under Louis XVI., and although continued at great expense by Napoleon, it is still not completed. The work was begun by the submersion of enormous conical frames of oak, having at the base a diameter of 140 feet, and 60 feet at the summit. These, and the intermediate spaces, were afterwards filled by dropping in large unhewn blocks of granite and sandstone, of which the whole mass is much overrated by some authorities. (Malte Brun.) The rade or road, thus formed on the southern side of this rampart, is sufficiently spacious for the anchorage of 100 vessels. A full description is given in Arthur Young's 'Voyage en France,' tom. i., p. 234, et seq. Cherbourg contains a population of about 15,000: it has a school for navigation, a college, a royal academy, a board of trade, a theatre, public baths, and a promenade.

The houses are of stone, and roofed with slate, of which there are several quarries in the neighbourhood. The church was founded in 960. The streets are narrow, gloomy, irregular, and very uncleanly, though water is abundantly supplied from several public fountains. There is some trade in corn, cattle, cheese, butter, and bacon, the produce of the neighbouring districts, and a small manufactory of coarse cloths and druggets. The environs furnish an ample supply of esculent vegetables and flax. In the adjoining forest of Tour la Ville there is a very extensive manufactory of glass, which employs about 200 workmen. The temperature of Cherbourg is very mild with respect to its latitude; the thermometer being constantly five degrees higher than at Paris. (Malte Brun.) The views of Napoleon respecting Cherbourg, as given in the Journal of Las Cases, are very interesting. (*Dic. Universel de Géog.*, 1825; Expilly; *Encyc. Méthodique;* Reichard's *Road Book of France.*)

CHERIMOYER, the fruit of a Peruvian downy-leaved species of Anona, the A. Cherimolia: it is described as the fruit most esteemed by the people of the western parts of South America, and is very like the Custard Apple of the West Indies. [Anona.] It is a tree about twelve feet high; the leaves are oval, pointed at both ends; the flowers solitary, very fragrant, of a greenish-white colour, and the fruit somewhat heart-shaped, with a scaly appearance on the outside; when ripe it is greyish-brown, or black. The flesh is white and sweet, mixed with several seeds of the colour of coffee. The Creoles think this fruit the best of the country; Baron Humboldt speaks of it in terms of high praise, and his account is completely confirmed by the testimony of many officers who have been in the South American service; but Feuillée says, one European pear or plum is worth all the cherimoyers of Peru. The latter author has figured it in his *Journal des Observations, &c.*, 3, t. 17.

CHEROKEES, the name of one of the native tribes, inhabiting the southern states of the North American Union. A century ago they formed a numerous and powerful nation, which was in possession of the southern portion of the Appallachian Mountains and the countries on both sides of the range, so that their hunting-ground extended over a part of the States of Tennessee, North and South Carolina, and Alabama, and over nearly half the State of Georgia. After a British colony had been settled in Georgia (in 1732), the native tribes began to lose ground. The Cherokees however maintained their footing for a long time, even after these countries had obtained their independence. Since 1790, they have sold different portions of their territories to the government of the United States. In 1809 they consisted of 12,359 individuals. In 1816 they ceded the country still possessed by them within the State of South Carolina, and some districts in Georgia and Alabama, receiving in consideration of this cession, besides presents and annuities, a tract of country of equal extent west of the Mississippi, to which some families emigrated. At the census of 1830 the Cherokees remained only in Georgia, where they amounted to about 5000 individuals; and in Alabama, where they were about half that number. In 1834 the State of Georgia resolved to expel them from that extensive tract of Georgia which lies to the west of the river Chatahoochee; and the better to effect this, they ordered the Moravian Brethren, who had settled among them for the purpose of instructing them in the Christian religion, to leave the country. No sooner had the intention of the government of Georgia become evident, than the Indians applied to Congress for protection, and Congress declared that the decree of the legislature of Georgia was illegal. But the State of Georgia decreed that Congress had exceeded its powers, and they enforced their own law by sending soldiers into the territory of the Cherokees in 1835 and expelling the Indians. Alabama at present is the only place east of the Mississippi where Cherokees are found: they occupy in this State the country about the upper branches of the river Coosa, and may consist of between 2000 and 3000 souls. [Alabama.] The remainder of this once powerful tribe is wandering about west of the Mississippi, on the banks of the Arkansas and White River.

The Cherokees are considered the most civilized of the American Indians. They have made considerable progress in agriculture and domestic manufactures, and in the raising of cattle. They chiefly cultivate cotton and Indian corn. They have a written language; the alphabet, which was invented by a native Cherokee, consists of 85 characters. Their language is derived from the same source as that of the Creeks, Chickasaws, Choctaws, Pasiagoulas, and some other tribes; and as all these tribes lived in the neighbourhood of Florida, these languages have obtained the name of the Floridian languages. (Franklin's *First Journey to the Polar Sea;* Darby.)

CHERRIS, an intoxicating drug, prepared from the common hemp.

CHERRY. [Cerasus.]

CHERRY, a valuable fruit, of which great numbers of varieties are known in our gardens; they are all the produce of *Cerasus avium*, or *C. vulgaris* [Cerasus], or of plants obtained by the intermixture of those two original species. Independently of their value as an article of luxury, and as yielding by distillation such liqueurs as Maraschino (so called because the Dalmatian *Maraschi* cherry is employed in its manufacture) and Kirschenwasser, cherries contribute essentially to the support of the poorer classes in some countries, not only in puddings and tarts, but as a principal ingredient in a kind of soup, and as a dried provision for winter. Their timber moreover is valuable for the more common kinds of cabinet-maker's work, and as in favourable soils they grow fast, they often afford to the planter a quick and good return for the outlay of his money. It is however only upon light sharp well-drained soil that the cherry thrives; when planted in stiff and wet soils it grows slowly, gums very much, and falls into a state of incurable bad health. Its varieties are multiplied by budding or grafting: the former is best performed upon the common wild cherry, the stones of which are collected by the nurserymen for that purpose. Like all other fruit trees that have been objects of cultivation, the cherry has given rise to a multitude of varieties, from among which it is difficult for any but professed gardeners to know how to make a selection. We should say that for all useful purposes the following are sufficient. The earliest are the Black Tartarian, and the Early Purple Guigne; the Early May, which ripens close about the same time, is not worth cultivation; these are succeeded by the May Duke, the Bigarreau, the Elton, and the Black Eagle; the Late Duke is the latest of the sweet cherries. For puddings there is the Kentish; for preserving in brandy, the Morello; for drying, the Belle de Choisy, the Flemish, and the Kentish. These are amply sufficient for a small garden, and are all good bearers: the Morello only actually requires a wall. If more variety is wished for, the Black Heart and the Downton may be added: and these are all out of the two hundred and nineteen varieties mentioned in the Horticultural Society's valuable Fruit Catalogue which are at all worth cultivating.

CHERSON (pronounced Kherson), a town in Southern Russia, 46° 40′ N. lat., and 32° 40′ E. long., was founded in 1778, on the right bank of the Limán, or æstuary of the Dnieper, which is here nearly four miles wide, when its numerous shoals are covered with water. It was designed to be the principal station for the Russian navy in the Black Sea, but it has not answered this purpose. It is only during the spring-flood that vessels of considerable size can pass from the town to the fortress of Kinburn, at the mouth of the Limán, and then only by means of camels. Still it contains docks for vessels of war, and merchant ships. It continues to be the principal depôt for all the stores which are required for the equipment of the fleet on the Black Sea, principally on account of the ease with which they may be conveyed to this port from the interior of Russia down the Dnieper. The town, which is regularly and well built, consists of four parts—the fortress, the admiralty, the Greek suburb, and the suburb of the marine soldiers. Its commerce is not considerable, and is carried on by the Greeks who inhabit the Greek suburb. The country about the town is very barren. In one of the villages, called Dauphigny, is a monument erected in honour of John Howard, who died here in 1796. Population 14,000.

CHERSONE'SUS (χερσόνησος), a Greek word signifying 'peninsula.' The term was applied more particularly to the small peninsula between the Hellespont and the Gulf of Melas, then called the Thracian Chersonesus; and to the peninsula now called the Crimea, which was called by the Greeks the Taurica Chersonesus.

CHERTSEY. [Surrey.]

CHERUSCI, a people of antient Germany, who bordered on the Catti and the Chauci, living inland or south of the latter, and near the banks of the Visurgis or Weser. The Cherusci being excited by Arminius, joined the Catti and others in the attack and defeat of Varus and his legions. They were afterwards defeated by Germanicus. After Germanicus left Germany and the Romans had drawn their legions back to the banks of the Rhine, the Cherusci quarrelled with the Suevi and afterwards with the Catti. Under Claudius the Cherusci sent messengers to Rome, to ask, as a king, for one Italicus, of the race of Arminius, who was born at Rome, of German parents. Italicus, however, on his arrival in Germany, was looked upon by many of his countrymen as an alien, and a degenerate descendant of Arminius. He was expelled from his kingdom, but afterwards recovered it with the assistance of the Langobardi. (Tacitus, *Annot.* xi. 16, 17.) In the time of Tacitus the Cherusci had declined from their former importance, having been overpowered by the Catti and other neighbouring tribes, and were considered as having degenerated. (*German.* 36.)

CHERVIL, a culinary vegetable, the Scandix cerefolium of botanists; it is an annual, and a native of the south of Europe; its leaves have a slight aromatic taste, and are used in soups and salads: it is little cultivated.

CHESAPEAKE BAY is the deepest indentation on the eastern shore of North America, between Florida Reef and the Bay of Fundy. The entrance, which is about 12 miles wide, lies between Cape Henry and Cape Charles, both in the State of Virginia, and is cut by the parallel of 37° N. lat. From the entrance the bay runs N., with a slight bend to the W. to 39° 33′ N. lat. or about 170 miles. Its breadth varies considerably. From its entrance to the mouth of the river Potomac, or for about 70 miles, its average width is 25 miles; but farther N. up to the river Susquehannah it does not exceed 10 miles. This would give a surface of about 2750 square miles. But in this calculation the smaller bays and channels are not included which are formed by the embouchures of the James River, York, Rappahannock, Potomac, and others, which may cover a surface of about 750 square miles, so that the area of the whole bay probably does not fall short of 3500 square miles.

A great number of considerable rivers fall into this bay which bring down all the waters from the eastern declivity of the Appalachian mountains, and from their numerous ranges between 37° and 43° N. lat. This circumstance might induce us to consider the bay as only a vast æstuary, especially as its shores are mostly low or very little elevated. But on the other hand we find that its depth is so considerable, that it may be navigated by large vessels in all parts, which does not answer the character of an æstuary Its shores also, even where there are no large rivers, are much indented, and form numerous harbours for vessels of different sizes. The bay and the rivers which flow into it are navigated by numerous steam-boats which keep up a ready communication between all the countries lying on the bay.

The great rivers which flow into the west side of the Chesapeake bay, taken from N. to S., are the Susquehannah, Potomac, and James river, all of which rise within the Appalachian range, where they flow in longitudinal valleys Besides these there are numerous smaller rivers, such as the Patapsco, Patuxent, Rappahannock and York river, all of which descend from the east slope of the Blue Ridge, and have no part of their course within the Appalachian range. Ships of war can ascend the Potomac to Washington, which is 120 miles from the mouth of that river, measured along its course, and near 200 from the entrance of the Chesapeake.

CHESELDEN, WILLIAM, a distinguished surgeon and anatomist of the last century, was born in Leicestershire, in 1688. His general education appears to have been limited, at least in point of time. At fifteen he commenced his medical studies in London, under the best instructors; and began himself to give lectures in anatomy in 1711, which he continued for twenty years with a reputation not far inferior to that of his master, Cowper. Becoming soon favourably known, he was elected a fellow of the Royal Society in 1712 at the age of twenty-three, and repaid this early distinction by a variety of interesting papers in the

Philosophical Transactions.' The most remarkable of them, communicated in 1728, is an account of the sensations of a youth of fourteen, blind from infancy, on recovering his sight by the formation of an artificial pupil. The memoir has been much quoted by metaphysical writers the operation, now common, was then perfectly new; and has added considerably and justly to Cheselden's fame.

In 1713 he published a work on anatomy which was long the text-book of that science in England, and was frequently republished both before and after his death. The eleventh edition was printed in 1778.

On the retirement of his tutor, Mr. Ferne, Cheselden succeeded him as surgeon to St. Thomas's, and was afterwards appointed consulting surgeon to St. George's and the Westminster hospitals. He turned these opportunities to good account in maturing his own skill and advancing the science of surgery, which is largely indebted to him. He was probably never surpassed in dexterity and success as an operator; his coolness never deserted him; and he is said to have been as much distinguished for the tenderness as for the judgment that directed his hand. We are told that out of forty-two patients whom he cut for the stone in four years, he lost but one; the present average being at least six in that number An eye-witness of many of his operations, the author of his éloge in the Memoirs of the French Academy of Surgery, of which he was the first foreign associate, assures us that he once extracted the stone in fifty-four seconds. Too much weight, however, may be attached to these surprising instances of success; even if truly recorded, they must have been in part the result of good fortune, or of a very judicious selection of cases for operation.

It is in lithotomy that Cheselden has most repute as an innovator as well as an operator. In 1723 he published a volume on this subject, recommending an improved method of performing what is called the *high* operation; but after more experience and investigation, he laid it aside for the *lateral* method, of which, as at present practised, he may almost be considered the inventor. His splendid work on the bones was published by subscription in 1733, with a dedication to Queen Caroline, to whom he held the appointment of surgeon. It consists of a series of plates of the natural size, with short descriptions; and is unequalled in execution, and, except in a few particulars, unsurpassed in accuracy. It was not successful as a speculation, and was attacked with bitterness, as had been his treatise on the high operation, by a lithotomist of the name of Douglas, who seems to have considered Cheselden an intruder.

In 1737, after a brilliant professional career, and, it is said, partly in disgust at the asperity to which his success had exposed him, Cheselden retired from practice at the age of forty-nine, and undertook the honorary duties of surgeon to Chelsea Hospital, which he retained for the rest of his life. His last contribution to science, made subsequently to his retirement, consisted of a series of plates with original remarks appended to Gataker's translation of Le Dran's Surgery.

In 1751 he suffered an attack of apoplexy from which he entirely recovered; but a return of the complaint caused his sudden death at Bath, on the 10th of April, 1752, in his sixty-fourth year. He was married, and left one daughter, the wife of Dr. Cotes, M.P. for Tamworth, who died without issue.

His reputation as a surgeon was solid, and will be lasting. As a man, much that is good is recorded of him, and nothing unfavourable, unless it be his fondness for pugilistic exhibitions, which might have their interest for him as an anatomist. He befriended Thomas Chubb, probably out of simple benevolence, as he is not said to have shared in his opinions. He associated with Pope and other wits of his time; but as his classical merit was certainly not considerable, their intimacy may be ascribed to his professional eminence and strong natural talents, rather than to the taste for literature and art, upon which he seems to have prided himself with no great reason.

CHESHAM. [BUCKINGHAMSHIRE.]

CHESHIRE, a county palatine on the west side of England. The name is formed from the antient city of Chester, and is an abbreviation of Chestershire, formerly written, in Saxon, Cestre scyre. The boundary line is very irregular. On the N.W. a tract of a peninsular form is included between the æstuaries of the Mersey and the Dee; and on the N.E. a long narrow tract, containing part of Featherbed Moss and Holme Moss, which belong to the central high lands of England, is included between the Thame and the Etherow, which by their junction form the Mersey. The county is said by some writers to be 'like the wing of an eagle stretched forth at length.' (King's *Vale Royal of Cheshire.*) The whole county received the name of Vale Royal of England, from the magnificent abbey so called, which was founded by Edward I. on the Weaver. Cheshire lies between 53° and 53° 34′ N. lat., and 1° 47′ and 3° 11′ W. long. Its northern boundary is chiefly formed by Lancashire, and partially by Yorkshire and the Irish Sea. The Mersey forms the boundary between Cheshire and Lancashire. On the east, the county has Derbyshire and Staffordshire; on the south, Shropshire and a small portion of Flintshire; and on the west, Denbighshire, Flintshire, and the Irish Sea. The greatest length of the county from N.E. to S.W., in a straight line, is about 58 miles; the greatest width from N. to S. about 32 miles: the whole circuit is nearly 200 miles. On the N.W. extremity, a line of sea-coast extends for about 8 miles from E.N.E. to W.S.W., besides about 20 miles on the æstuary of the Mersey, and about 14 on the great æstuary of the Dee. The area of the county is 665,600 acres, or 1040 square miles; to which may be added 10,000 acres as the sands of the Dee. (Ormerod's *Cheshire*, vol. i. p. xliv.) According to Mr. Holland (*Agricul. Survey*) there are 676,000 acres, of which [illegible]0,000 are in cultivation, including parks and pleasure grounds; 28,000 in waste lands, commons, and woods; 18,000 in peat bogs and mosses, and 10,000 in sea-lands on the æstuaries of the Dee and Mersey The total population of the county, in 1827, was 270,098; in 1831, 334,410. (*Boundary Report.*) Chester, the county town, is 183 miles N.W. from London.

Surface, Hydrography, and Communications.—The surface of Cheshire is in general a nearly uniform level, but there are a few inequalities. There are several elevated tracts stretching in a general north direction. One is between the Goyt and the Bollin; and a second between the Bollin and the Weaver. A tract of high land extends also from N. to S. across Delamere Forest, terminating to the N. near Frodsham in a high promontory which overlooks the Mersey, and to the S. in the rock on which Beeston Castle stands; the height of this rock is 366 feet above the sea. Alderley Edge, a few miles N.W. of Macclesfield, is an isolated hill which rises abruptly out of a level country, and presents one of the richest and most extensive prospects in the county; but Cheshire, from its general flatness, is not in general remarkable for picturesque beauty. In the eastern part of the hundred of Macclesfield are several extensive tracts of black moor, or bogs of peat-moss; and in the vicinity of Macclesfield are the high lands already referred to between the Bollin and the Goyt, which spread eastward into Derbyshire, and form on the Cheshire side a kind of mountain-wall. These high lands appear also near Congleton, and stretch southward to Talk, in Staffordshire. In former times there were numerous forests in Cheshire; one is mentioned in the Domesday Survey of Alticross as being ten miles in length and three in breadth. At present there are only a few large woods. Some at Dunham Massey contain many noble old oaks. Around Delamere Forest, in the hundred of Eddisbury, there are several extensive plantations, chiefly of Scotch firs and larches. This forest, so called, is a large sterile tract of whitish sand, partially covered with heath and peat-moss. It occupies 10,000 acres; of which a considerable part has been enclosed and brought into cultivation. The most extensive plantation in the county is that of Francis Jodrell, Esq., which covers 1000 acres. The timber supplied by the great profusion of hedge-row trees makes ample amends for the loss of the antient forests. It is principally oak, and furnishes abundance of tanner's bark. A large quantity of fine timber is also produced on the numerous estates of the nobility and gentry; especially on those of Earl Grosvenor, of the Earl of Stamford and Warrington, and of the Marquis of Cholmondeley. In many parts land left to itself becomes spontaneously covered with oak and alder.

Cheshire abounds not only with rivers and brooks, but with broad sheets of water called meres, which generally contain fish. The principal are Oak mere, Pick mere, Budworth mere, Rosthern mere, Mere mere, Tatton mere, Chapel mere, Moss mere, Broad mere, Bah mere, and Comber mere, which is three-quarters of a mile in length.

The chief navigable rivers are the Dee, Mersey, and Weaver. The navigation of these rivers is superintended, and has been greatly improved, by companies incorporated by acts of parliament. The source of the Dee is in Merionethshire, where, in conjunction with another rapid stream descending from the heights between Dolgelly and Dinasmowddy, it forms the lake Tegid, or Pimble mere, otherwise called Bala lake, the largest in Wales. Passing Bala and Corwen, it runs E. through Denbighshire, by Llangollen, nearly to Overton, in Flintshire, where it turns northward to Bangor. Continuing in the same direction, it becomes the boundary of Cheshire nearly from Worthenbury to Aldford. It then intersects the northern part of the hundred of Broxton to Chester, which it half encircles. From Chester it flows in a straight artificial cut into the broad æstuary of the Dee. A surface of about 2500 acres has been reclaimed from the S.E. extremity of this æstuary. From Bangor bridge the Dee is navigable for barges. At Chester bridge it is 100 yards wide, and vessels of considerable tonnage can pass by the new channel to Chester. The whole length of the course of the Dee is about 55 miles. It supplies salmon, trout, and other kinds of common fish. This river, called, in Latin, Deva, in British, Pifir dwy, was antiently held in great veneration, and its waters were considered sacred for religious ablution. As such it is celebrated by Drayton, Browne, Spenser, and Milton. (Dr. Warton's note on Milton's *Lycidas*, Todd's ed., vol. v.)

The Mersey in its whole course divides Cheshire and Lancashire. It is formed, and first receives its name, by the confluence (near Stockport) of the Thame and Goyt: the Etherow (which joins the Goyt a little above Stockport) and the Thame rise in the central highlands, N. and N.E. of Stockport; the Goyt rises near Buxton on the east side of the highlands between Macclesfield and Buxton. Leaving Stockport the Mersey runs a general west course to Northenden and Ashton. After passing by Carrington, it receives on the right bank the Irwell from Manchester, and on the left, a little below Warburton, the Bollin. It continues with a very winding course through a low, flat country past Warrington, and expands at its junction with the Weaver into a wide æstuary which forms the Liverpool channel; and though much obstructed by banks of sand, is rendered safe by the excellent system of pilotage. The Mersey is navigable from its confluence with the Irwell. At Warrington it is 40 yards in width; opposite Liverpool the width is a mile and a quarter, with a considerable depth at low water. The greatest width of the æstuary above Liverpool is between Eastham and Frodsham, where it is above three miles wide. Its whole course from Stockport to the outlet of the æstuary is about 55 miles. A large marsh at the confluence of the Weaver, extending to Helsby and Frodsham, is subject to occasional inundations. The river and æstuary contain congers, plaice, flounders, and shrimps; with annual shoals of smelts, called sparlings, remarkable for size and flavour. Some remarks are made in Ormerod's *Cheshire* (vol. ii.) on the antient communication of the S.E. extremities of the æstuaries of the Mersey and the Dee; by which the present peninsula of Wirrall was made an island.

The Weaver traverses the central parts of Cheshire from S. to N. It rises in the north of Shropshire, near the village of Stych, and after receiving several considerable brooks and rivulets, runs by Nantwich, Minshull, and Winsford, to Northwich, where it forms a confluence on the right bank with the Dane, which rises in the same swamp as the Goyt, and, a little farther north, with the Peover. It then winds W.N.W. and falls into the Mersey below Frodsham. From Winsford to Frodsham it has been rendered navigable by ten locks; the total fall being 50 feet. About 120 vessels, from 20 to 100 tons, convey rock-salt down the river, and return with coal. The whole course of the Weaver is about 40 miles. Among the less important rivers is the Dane, which is joined by the Wheelock above Northwich. The source of the Bollin is in Macclesfield forest, near that of the Dane. It passes Macclesfield and Wilmslow, is crossed by the Bridgewater Canal, and enters the Mersey near Warburton, after a course of about 23 miles. The Peover rises S. of Macclesfield, near Gawsworth, and flows W.N.W. to its junction with the Weaver near Northwich.

Several canals intersect the county. The Bridgewater Canal enters Cheshire by crossing the Mersey near Ashton. Its length within the county of Cheshire is about 24 miles. [BRIDGEWATER, DUKE OF.] The Grand Trunk, or Trent and Mersey Canal, which was commenced in 1766, runs south-east from Preston Brook, by Northwich, Middlewich, and Sandbach, and leaves Cheshire at Church Lawton, on the borders of Staffordshire. Between Preston on the Hill and Dutton, not far from its commencement at Preston Brook, it passes through a tunnel 1241 yards in length; at Barnton, through another of 572 yards; at Saltersfield, through one of 350 yards; and finally, at Hermitage, through another of 130 yards. The whole of its line in Cheshire is about 20 miles.

The Chester and Nantwich Canal, which connects these two towns, was completed in 1778. At Chester it forms a junction with the Dee, and with the Dee and Mersey Canal, which runs across the peninsula of Wirrall to the Mersey, at Ellesmere Port. Four miles north of Nantwich, a branch from the Chester and Nantwich Canal runs to Middlewich, and is called the Middlewich branch. From the point where the Chester and Nantwich Canal and the Middlewich branch unite, the canal which thence runs south to Nantwich, and past Audlem into Shropshire, is called the Birmingham and Liverpool Junction Canal. The Ellesmere Canal branches off from a point between Nantwich and the point where the Chester and Nantwich Canal is joined by the Middlewich branch, and runs to the neighbourhood of Whitchurch. From Church Lawton the Macclesfield canal runs past Congleton, Macclesfield, and so on northwards to the Peak Forest Canal, which it joins a few miles north of Disley.

The Peak Forest Canal enters Cheshire at Ashton-under-Lyne, where it crosses the Thame, and passing near Disley, quits the county at Whaley Bridge. It crosses the Goyt below the junction of the Goyt and Etherow, by an aqueduct 100 feet in height, which has three arches, each 60 feet span and 78 feet high.

Several important roads traverse this county. The road from London to Manchester by Derby enters the county near Bosley, and passes through Macclesfield and Stockport. Another branch of the same line enters at Whaley Bridge, and leaves the county at Stockport. The road from London to Manchester by Lichfield runs through this county by Church Lawton, Congleton, Wilmslow, and Cheadle. The road from London to Liverpool also enters at Lawton, and runs to Warrington by two branches, one through Knutsford, the other through Middlewich and Northwich. The Birmingham and Liverpool Railway, as projected, enters the county near Belley on the south, and runs a little to the west of Middlewich and Northwich to the Mersey, which it crosses near Warrington.

Geological character.—The general character of the Cheshire soils is a clayey or sandy loam; tracts of peat-moss cover a large extent of the eastern portion of the hundred of Macclesfield. Some mosses of smaller extent are at Warmincham and Coppenhall. The latter, which is almost cleared of peat, contained numerous trunks and branches of trees, chiefly of oak, beech, and fir, apparently broken off at different heights, and partially exhibiting the marks of fire. An antient road of gravel passed through the moss of Coppenhall.

The range of high land to the east of Macclesfield is a sandstone rock, which contains beds of coal: this sandstone range is bounded on the east by the limestone of Derbyshire. The high land, which includes Delamere forest, is also sandstone.

The most important mineral productions of Cheshire are fossil or rock-salt, and coal. The rock-salt is obtained near the banks of the Weaver and its tributary streams. It was first discovered near Northwich, in 1670, in searching for coal; it has since been found very abundantly in the townships of Witton, Wincham, Winnington, and Marston, near Northwich. There are salt-works also at Nantwich, Middlewich, and Winsford. It is of two kinds, the one white and transparent, the other of a reddish-brown. The former has been found by analysis to be an almost pure muriate of soda: the latter contains a small portion of oxide of iron, from which its colour is derived.

The principal salt-works are in the neighbourhood of Northwich, where alone there are mines, in addition to brine-springs. The rock-salt is found from 28 to 48 yards beneath the surface of the earth. The first stratum is from 15 to 25 yards in thickness, extremely solid and hard, and resembling brown sugar-candy. Many tons at a time are loosened by blasting with gunpowder. The second stratum is of hard stone, from 25 to 35 yards in thickness. The salt lies beneath this stratum, in a bed above forty yards thick, generally perfectly white and clear as crystal. The ex ternal surface above these strata is of whitish clay and gypsum. About 60,000 tons of salt are annually taken from the pits in the neighbourhood of Northwich. Besides this quantity of fossil salt, not less than 45,000 tons are annually manufactured at the same place from brine-springs, which are from 20 to 40 yards in depth.

Coal of a good quality is found abundantly in the north-east part of the county, especially in the townships of Worth and Poynton, where there are very extensive collieries, which supply the manufactories of Stockport. At Denwall, in the hundred of Wirrall, there is also coal. Copper and lead are found at Alderley Edge and the Peckforton Hills; the former place supplies a considerable quantity of cobalt. There are several quarries of excellent freestone in this county, of which those at Runcorn, Manley, and Great Bebington, are the most important. Limestone is found only at Newbold Astbury. Mowcop Hill, or Molecop, which is partly in Staffordshire, has long been famous for its mill-stones. Marl is found in almost every part of the county, and is generally used for manure. Dr. Woodward (*Cat. Brit. Fossils*) speaks of a fibrous stalky substance, a kind of asbestos, as found in great abundance in beds of marl about High Legh. At Bug Lawton is a sulphur-spring, which is serviceable in scorbutic affections; and at Shaw Heath, near Stockport, a chalybeate of considerable strength.

Agriculture.—The soil and climate of Cheshire are peculiarly well adapted for the growth of grass. The soil is mostly composed of loams of various degrees of tenacity, and the climate is moister than the more eastern parts of England. Situated in an extensive plain between the Derbyshire and Welsh mountains, Cheshire is seldom exposed to long droughts. The low meadows along the banks of the rivers are very subject to be flooded, which is one reason for keeping them in grass. Two-thirds at least of the county possesses a soil above mediocrity, of which the greater part is in permanent pasture, and produces the excellent cheese known as Cheshire cheese. The arable land is generally that which is thought too sandy for pasture, or of which the grass has deteriorated by neglect. Hence the arable part of a farm in Cheshire is seldom cultivated with that attention which is paid to similar land in those counties where good grass land is scarce. There are very few farms which consist chiefly of arable land. There is every where a predilection for the dairy. It may be safely asserted that, with the exception of gentlemen who hold farms in their own hands, of whom there are many of considerable wealth in the county, there are few farmers who deviate from the old routine, or seem inclined to adopt improved systems of cultivation. At the same time, there are perhaps few counties in England so susceptible of material improvement as Cheshire. It possesses great advantages; an easy communication by canals and rivers with the most populous manufacturing districts, and consequently a certain market for its agricultural products. According to the report to the Board of Agriculture, the county is divided as follows:

	Acres.
Arable and meadow land, including parks and pleasure grounds	620,000
Waste lands, commons, woods (a considerable part of which has been inclosed since)	28,000
Peat bogs and mosses	18,000
Sea lands in the æstuaries of the Dee and Mersey	10,000
	676,000

There are many large proprietors resident in Cheshire, but the class of yeomen is much diminished, and is replaced by small proprietors, chiefly retired tradesmen and artificers, or small farmers little raised above the common labourer.

Dairy farms require considerable buildings, and some have been erected by wealthy proprietors in the best and most substantial manner. The habitations for the family are quite sufficient for their comfort: many of the cow-houses are constructed on the Dutch plan. The heads of the cows are turned towards each other, with a passage in the middle for a small cart, by which the fodder is brought directly before the cows. It is thus given to them with greater cleanliness and economy than in any other way. Where many cows are kept, this will be found by far the most convenient arrangement of a cow-house. There is a description of one of these cow-houses in the 'Agricultural Report of Cheshire' [illegible], erected at Ollerton, near Knutsford, which combines simplicity with great convenience. Large farms are not common in Cheshire. The average size may be considered as from 50 to 150 acres, that quantity being sufficient for the full employment of a family, and for a dairy of twelve to twenty cows. The rent of land is higher than that of the same quality in other parts of England, which is owing to the smaller outlay with which a dairy farm is managed. The implements of husbandry are in general such as have been in use for ages; a heavy ill-constructed plough, drawn by four or five horses in a line, with which they plough three-fourths of an acre of the heavy loams in a day. Harrows and rollers, the latter occasionally armed with spikes, are used to break the heavy lumps which the plough turns up, when the sun has baked them. Improved instruments are in use amongst the gentlemen farmers; but their example is seldom followed by the common renters of land. The effect of the dairy husbandry may be observed all through the county. Land is ploughed in order to have winter fodder for cattle, and to improve pastures overrun with weeds. Where the land is fit for turnips, which is not often the case, they are raised for the cows. Cabbages have been cultivated with some success in several farms, but there is no improvement in the mode of cultivating corn crops. It is not uncommon to see two or three crops of oats taken in succession from newly broken up land, and the last laid down with grass seeds. In this exhausted state it produces no good grass for many years, but plenty of weeds. The introduction of a good system of convertible husbandry would double the present produce of Cheshire. But we will not venture to affirm that the dairy produce would be improved at the same time. When land is brought to a high state of cultivation, and the artificial grasses give a great bulk of fodder, the quality of the cheese is often deteriorated; or to speak more correctly, the process must be varied. It is much easier to make cheese that will keep from poor pastures than from rich.

There is a simple instrument in use in Cheshire which deserves notice. It is a small strong scythe, called a hodding scythe, used to cut up rushes in pastures. It has a short handle, and the blade, which is about twenty inches long, is bent like a portion of a hoop. By a dexterous use of this instrument in spring, a man cuts up a tuft of rushes with a great portion of the roots, and as a hollow is left the water enters into the cut part of the remaining roots and rots them. The hollows should then be filled up with earth, and grass seeds sown over them. The rushes and roots cut off are put in a heap to rot, which is readily effected by the addition of quick lime, and thus an excellent compost is formed.

The cultivation of potatoes has been much encouraged in Cheshire, by the demand in Liverpool and the manufacturing districts. In that part of the county which lies along the æstuary of the Mersey, great quantities of very good potatoes are raised. The sandy and turfy soils, which are unfit for permanent pasture, are peculiarly fitted for the growth of potatoes. The neighbourhood of Frodsham has been long noted for the great quantity of potatoes it produces. The produce on good land is upwards of 10 tons per acre, but they require at least 25 tons of manure. The best potatoes grow on land broken up from grass, which had been laid down in a rich state; in this case no manure is required. When potatoes are very plentiful, and the price low, they are given to cattle, either boiled or raw, and in this way they are worth more than any other root, and produce much excellent manure. Early sorts are raised for the Liverpool market by a slight forcing. They are laid in a dry chamber and protected from the frost; they shoot early, and in that state, one shoot only being left, they are put into the ground in February, and occasionally protected by mats or straw. A slope of the beds towards the south-west is reckoned the most favourable exposure. They come in a month earlier than those planted at the usual time, and the land is cleared by the beginning or middle of June: a second crop is then put in, to be dug up in November. A warm sandy soil suits the early potatoes best. Near Warrington early potatoes are set in wide rows, and cabbages are planted between them: when the potatoes are taken up, the cabbages have the mould drawn round their stems, and attain a good size in spring. This is a cultivation which deserves to be more generally introduced on good strong loams.

Grass land is considered so much more valuable than arable, that most leases contain a clause, 'that not more than one-fourth of the farm shall be ploughed.' Many farms have little or no arable land attached to them. A soil which is rather stiff is considered the best for grass, especially if there be a substratum of marl, which is the case in many parts of the county. The marl, when spread over the surface, materially improves the herbage. A very rich loam is not considered so good for pastures where cheese is made, as one less fertile, as it is apt to make the cheese heave. In Nantwich, and the western part of Northwich hundred, the substratum is chiefly marl, and the soil a stiff clay.

The natural grasses found in the good pastures are chiefly of those kinds which have been most approved of for sowing, when arable land is laid down to grass; viz., Poa pratensis, Poa trivialis, Festuca pratensis, or, on sandy loams, Anthoxanthum odoratum. In the Report it is stated that Rhinanthus Crista galli, commonly called yellow rattles, is very common in the pastures, and is said to be readily eaten by the cattle. It is in most places considered a sign of poor land, and lessens the value of the hay. The Cheshire farmers often defer mowing the grass for hay in a dry summer, in the hope of having a greater crop by waiting for showers; but this is a mistake, since it is much more profitable to cut the grass, however light the crop may be, as soon as the principal grasses are in flower, when the stalk contains the most nutritive juices.

Although much of the soil in Cheshire is well suited for fruit-trees, orchards are not common: the marly substratum is not well adapted for the roots of trees; deep, alluvial, and loose soils, are the best. The hedge-rows are in general well filled with trees, which gives the country, when seen from an elevation, the appearance of a continued forest. The forest of Delamere, as it is called, although, like many other antient forests, a great part of it is a mere waste without any woods, formerly contained 10,000 acres. It is now much reduced by enclosures, but a great portion is still waste.

Draining has been introduced extensively, and with the best effect, in order to carry off the superfluous surface water, which is common in many parts of the county. The shoulder drain is common in stiff soils. Paring and burning are not much practised, and this mode of preparing land for crops is in general reprobated by landlords as destructive of the soil; but when old worn-out pastures are overrun with bad grasses and weeds, there is no improvement more effectual.

The abundance of marl found in Cheshire is one of the chief means of improving the poor soils; 130 solid yards, or tumbril loads, of marl are put on an acre in the summer months, and left on the surface all the winter. In spring it is ploughed in, and makes the manure put on afterwards go much farther. Marling is a permanent improvement. Lime, and also sand, are put upon strong heavy lands to ameliorate the texture; the first does so, when put on in any proportions; the latter must be put in considerable quantities, and not ploughed in deep. It is a great improver of cold wet pastures, especially after they have been drained.

In the neighbourhood of the salt mines, refuse salt has been used for manure, and with success; but whether it owes its virtue to the salt, or to the earthy ingredients mixed with it, is still doubtful.

The number of rivulets in Cheshire might naturally suggest the applying of them to the purpose of irrigation; but this has been done in a few instances only.

In some places, where a rivulet could be turned, so as to flow through a farm-yard, and afterwards irrigate meadows situated lower down, advantage has been taken of this, as an easy mode of conveying the manure over the grass; in this they have imitated the common practice in most farms in Switzerland.

From the great number of dairy-farms in Cheshire, one would naturally expect to see considerable attention paid to the breed of cows; but, till lately, this was not the case; there were cows of all breeds, and crossed in every possible way. The great superiority of the improved short-horn breed has however made them more generally sought after. Some of the dairies have very fine herds, or packs, as they are called there, of short-horned cows, and some of Ayrshire cows; but this is by no means yet general; purity of blood is not much thought of. When a cow is a good milker, her cow-calves are weaned; and those heifers which are raised on the farm are thought to produce the most thriving cows. A cow is considered in her prime at four or five years old, and continues so till she is ten or twelve, after which she falls off, and should be fatted for the butcher. 'A good milker has a capacious and thin udder, without much flesh on it, teats standing well apart, and not too large; a deep belly, with very prominent milk veins; a light fore-quarter, wide loins, thin thigh, white horn, thin head, clean about the chaps and throat, and a full lively eye.' (*Agricultural Report.*) A cow that gives much milk is never fat, and her hip-bones project: her ribs appear distinctly under the skin. It is estimated that there are about 100,000 cows in the county, each of which gives on an average 2½ cwt. of cheese in the year; that is, altogether, 250,000 cwt., or 1250 tons. Each cow gives on an average about eight quarts of milk per day; some few give much more, and even as much as 24 quarts per day; but this is extraordinary, and only for a short time. Four quarts of milk make one pound of cheese; it takes from 12 to 15 quarts to make a pound of butter. A cow is in full milk for six months after calving, then three months in half milk, and three months dry. A plentiful supply of good fresh food, such as clover or tares, cut and carried to the stall, will often double the average of milk; but this is seldom practised in dairy counties. The cows are generally housed in November, or kept in yards, which is better. During the winter they are let out for a few hours each day into a paddock, or small meadow, near the homestead; they find nothing to eat there, but it gives them an appetite for their dry food when they come in again. Stall-feeding cows has been attempted, and with success; but this occasions too much trouble for the dairy-farmer, although the produce may be much increased, and the manure will amply repay the expense of the daily cutting and carrying of the fodder. Cow-calves which drop in February and March are usually reared: they are left three weeks to suck the cow, after this they have warm whey given them to drink, or oatmeal-gruel mixed with whey. Flax-seed, steeped in water until a jelly is formed, is also given them by some. For the first winter they have hay, in the next only straw. The heifers take the bull at two years old.

The making of Cheshire cheese is described minutely in the Agricultural Report for the county, to which we refer, as well as to the Article [Cheese.]

Butter is made from the cream or from the whole milk allowed to coagulate and become sour. Good butter may be obtained in either way; but that made from fresh cream is always the best. An inferior butter is made from the cream which rises on the whey. [Butter.]

A considerable part of the profit of a well-managed dairy arises from the feeding and selling of pigs; but fewer pigs are kept in Cheshire than the dairies would warrant. The fatting of calves for the butcher is probably not so profitable, from the want of demand for veal in the country, as it would be nearer the metropolis.

The wages of agricultural labourers are good on the whole, and they are in general laborious and provident. The neighbourhood of manufactures tends to raise the wages.

The sheep husbandry, which is so profitable to the farmer in other counties, is scarcely known in Cheshire. Sheep do not go well with cows, as they pick out the finest herbage before it is long enough for the cow to graze. Some few are kept to consume the grasses which the cows refuse; they are seldom kept over the year, and are sold as soon as any profit is realized.

On the whole Cheshire is inferior to many other counties in agriculture, but it contains more means of improved husbandry than most. It wants only the application of capital, and the superintendence of men of true practical science, to become one of the finest agricultural counties in England.

Fairs.—Altringham, April 29, August 5, November 22; Budworth, February 13, April 5, October 2; Congleton, May 12, July 5, November 22; Chester, February 25, April 27, July 5, October 2, November 24; Frodsham, May 15, August 21, December 13; Knutsford, Whit-Tuesday, July 10, November 8; Macclesfield, May 6, June 22, July 11, October 4, November 11; Malpas, April 5, July 25, December 8; Middlewich, Holy Thursday, August 6; Nantwich, February 4, March 15, September 4, December 11; Northwich, April 10, August 2, December 6; Over, May 16, September 25; Sandbach, Easter Tuesday, Tuesday after September 10; Stockport, March 4—25, May 1, October 23; Tarporley, May 1, last Monday in August, December 11; Winsford, May 8, November 25.

Divisions, Towns, &c.—When the Domesday survey was taken, this county, exclusively of the lands between the

Ribble and the Mersey, now a part of Lancashire, though then considered a part of Cheshire, was divided into twelve hundreds. Except a few townships, the two antient hundreds of Atiscros and Exertan have also been taken from Cheshire, and added to the counties of Flint and Denbigh. The present division of the hundreds is supposed to have been made in the reign of Edward III.; and Lysons gives the proportion or relative size of old and new hundreds under the following table:—

New Hundreds.	Old Hundreds.
Wirrall,	Wilaveston.
Broxton,	Dudestan and Castra.
Eddisbury,	Riseton and Roelan.
Northwich,	Mildestric.
Nantwich,	Warmondestron.
Macclesfield	Hamestan.
Bucklow,	Bochelau and Tunendune.

It is to be observed that several of the townships which were in Dudestan are now in Eddisbury, and other variations have taken place; but the general arrangement of the hundreds of Cheshire is exhibited by the table.

Lysons states the number of market-towns to be twelve, excluding Chester:—namely, Altringham, Congleton, Frodsham, Knutsford, Macclesfield, Malpas, Middlewich, Nantwich, Northwich, Sandbach, Stockport, and Tarporley. Of the less important of these places we subjoin some account; those which are large enough to receive distinct notices are described elsewhere. [ALTRINGHAM, CONGLETON, MACCLESFIELD, NANTWICH, and STOCKPORT.]

Tarporley, in the hundred of Eddisbury and deanery of Chester, is a small market-town, near Beeston Castle, on the great road from London to Chester, from which it is distant ten miles east-south-east. It was antiently governed by a mayor, but at present by a constable. In 1642 a battle was fought at this place between Sir Wm. Brereton's forces and the Royalists from Chester, who, on this occasion, were victorious. Tarporley is pleasantly situated, cleanly, and neatly built, and is chiefly known as the scene of an annual fox-hunt in November, which is numerously attended by the county gentry, the neighbouring heaths being very favourable for this amusement. The church is an antient structure of the red sandstone, which abounds in this county: its interior contains several monuments, with inscriptions interesting to the antiquary, and some armorial bearings in windows of coloured glass. The living is a rectory, of which the net annual income is 644*l*. The inhabitants are chiefly employed in the manufacture of stockings and leather breeches. The market is on Thursday. There is an alms-house and Wesleyan chapel. Population, 1000.

Sandbach, a market-town in the hundred of Nantwich and deanery of Middlewich, was formerly celebrated for its ale. It occupies a pleasant eminence near the river Wheelock, and commands several extensive and picturesque views of the Vale Royal, the Staffordshire and Derbyshire hills, and the distant mountains of Wales. The worsted trade and manufacture of shoes, which formerly prevailed, have been succeeded by the silk manufacture, by which the town has risen to greater importance. It has some brine springs in the vicinity. In the market-place are two antient crosses, with sculptured images of the crucifixion. The living is a vicarage, of which the net annual income is 213*l*. Market on Thursday. Population, 6516.

Frodsham is 191 miles north-west from London; the population is 1746. This township is pleasantly situated on a rising ground at the foot of the hills which border on Delamere Forest, near the junction of the Weaver and the Mersey. Salt works and cotton manufactures are the chief employments of the inhabitants. The town is formed chiefly by two streets which intersect each other, and there is a graving-dock and yard for building and repairing vessels. The living is a vicarage, in the archdeaconry and diocese of Chester; the patron is Christ Church, Oxford: it is of the annual value of 590*l*. The church is a fine antient structure. Beacon Hill has some pleasant walks and fine views. On a site now occupied by a handsome modern mansion, stood formerly at the west end of the town a castle which Edward I. gave to David Llewelyn, the last sovereign prince of Wales, which was afterwards held by the earls of Rivers, and was consumed by fire in 1642. The parish of Frodsham is about thirty miles in circumference, and it contains eight townships. It abounds in springs, and produces large quantities of potatoes, which are used chiefly by the manufacturers of Lancashire. The Wesleyan Methodists have a meeting-house in Frodsham. There is a free-school, the salary of which is 100*l*., and the teacher has besides a good house in Overton. There is also a charity for the relief of the orphans and widows of the clergy.

Knutsford, situated on the great road from London to Liverpool, is 172 miles north-west by north from London; the population is 3040. The market-day is Saturday. The name is said to be derived from Canute, the Dane, who passed with his army over the small branch of the Bollin, which runs past the town. The town is in the hundred of Bucklow, and is divided into Higher and Lower Knutsford by a branch of the river Bollin, which rises about half a mile to the south, and passing the turnpike road falls into Tatton mere. In Lower or Nether Knutsford there are a spacious county prison, a handsome town-hall, and the market-place. Knutsford was formerly part of the parish of Rostherne, but was made a distinct parish in 1741. The living is a vicarage, in the archdeaconry and diocese of Chester, of the annual value of 225*l*. The church is built of brick and stone, with a square tower. The Dissenters have three meeting-houses and two charity schools. Thread, worsted, and leather are the principal manufactures. Races are held every July near the town.

Malpas, situated on an elevation near the river Dee, in the hundred of Broxton, is 168 miles north-west from London: the population of the parish 5565, of the town 1004. The parish contains two rectories, one with the curacy of St. Chad, and the other with the curacy of Whitwell. The church was formerly the chapel of a religious house for monks of the Cluniac order; it is built of unhewn stone, and consists of a nave and chancel, without either aisle or steeple: it is highly ornamented, and some of its decorations have been supposed to be of Saxon origin. Courts leet are held here for the recovery of debts under 40*s*. Besides several meeting-houses, there are here two chapels of ease, an endowed grammar school for 12 boys and 12 girls, and also many charitable institutions. Malpas is the birth place of Matthew Henry, the commentator on the Bible.

Middlewich, situated near the confluence of the rivers Dane and Croke, is 167 miles north-west of London: the population of the parish is 4785, of the town 1325. Market-day is Tuesday. This town derives its name from its position between the wiches or the salt towns. Great quantities of salt are manufactured from the salt-springs here; cotton fabrics are also made. The Grand Trunk Canal runs through the town on its course to the Mersey. The living is a distinct vicarage, in the archdeaconry and diocese of Chester, of the net annual value of 128*l*. The church is large, and on the south side of it are a college and an oratory; the latter founded by the Leigh family of Lyme; the former by Thomas Savage, archbishop of York. The Dissenters have three meeting-houses; and there is a free-school. The petty sessions are held at Middlewich for the hundred of Eddisbury. The Rev. Theophilus Lindsay, a Unitarian divine of some note, was born here.

Northwich, in the parochial chapelry of Witton, is 1[illegible] miles east-north-east of Chester, and 173 north-west of London: the population, 1490. Camden states that it was called by the Britons Hellath, or Hellah Du, that is, the Black Salt Town. It is in the line of the northern Watling Street. The town was fortified and garrisoned by the parliament party in 1643, and was taken by the royalists and retaken by their enemies. The principal manufacture is salt. The Weaver runs through the town. Vessels of small burden are built here in the ship-yards. The market-day is Friday. Courts-leet and baron are held, though the general quarter-sessions were removed to Knutsford in 1784. The Independents and Wesleyan Methodists have meeting-houses in Northwich, and there has been a charity school for 12 poor children, with a small endowment, since 1735. The living is a curacy, in the archdeaconry and diocese of Chester. The church, which is spacious, has a semicircular choir, and the roof of the nave is decorated with numerous figures of wicker baskets, such as are used in salt-making.

Over, a small town, about four miles west of Middlewich, is governed by a mayor; but the commissioners appointed to make the recent inquiry into Municipal Corporations say that it does not appear under what warrant or authority the borough of Over is governed by a mayor who is also a justice of the peace within the limits of the borough and lordship. The population in 1831 was 2601.

Ecclesiastical and Legal Jurisdiction.—This county, in antient times, was subject to the ecclesiastical jurisdiction of the bishops of Mercia, who had their seat at Chester. In the time of William the Conqueror, and during three successive centuries, this diocese was styled the bishopric of Chester. (For further historical accounts, see Lysons and Ormerod.) Of these 86 parishes 46 are rectories, 23 vicarages, and 18 donatives, or perpetual curacies; many are of great extent. The parish of Prestbury comprises 32 townships and 14 chapelries. The county is in the diocese of Chester, and province of York: it forms an archdeaconry, and comprises the seven deaneries of Chester, Frodsham, Macclesfield, Nantwich, Malpas, Middlewich, and Wirrall. Cheshire is in the South Wales circuit.

Cheshire, before the Reform Act, sent four members to parliament: it is now formed into a north and a south division, each of which sends two members to parliament. The north division contains the hundreds of Macclesfield and Bucklow, and the south division contains the remaining hundreds.

The boroughs of Cheshire, Macclesfield, and Stockport, each return two members to parliament. The places of election for the north and south divisions respectively are Knutsford and Chester.

Manufactures.—The cotton and silk manufacture is extensively carried on in and around Stockport, Macclesfield, Marple, Congleton, and Sandbach. At Knutsford there is a large manufactory of thread. At Nantwich, and the places just named, are manufactories of hats for exportation, and of shoes at Sandbach. Some woollen cloths are also made in the same district. Tanning is very extensively carried on throughout the county. There is also a large manufacture of gloves, ribbons, and buttons. The copper, lead, and iron, of the Alderley Edge and Peckforton Hills, are manufactured in the county, and constitute a small item in the export trade. But cheese is the principal product, which is not only well known and highly esteemed in every part of England where the consumption is immense, but also in most parts of Europe. The whole annual produce of this article in Cheshire is about 11,500 tons, of which 4000 tons are exported. (Holland's *Agricul. Survey.*) The prime cheese is made chiefly in the districts where the salt abounds; that is, along the banks of the Weaver. Potatoes are raised in very large quantities, especially in the western portion of the county, including the peninsula of Wirrall. In the parish of Frodsham alone about 100,000 bushels are annually produced. Besides a prodigious home consumption, they are exported in great quantity by the Mersey to Liverpool and Manchester.

Civil History and Antiquities.—At the time of the Roman invasion this county formed part of the territory occupied by the Cornavii or Carnabii, a name which Whitaker conjectures the inhabitants of this district derived from the peculiar form of the peninsula between the æstuaries of the Dee and the Mersey. In the first division of Britain by the Romans it was included in Britannia Superior; and in their subsequent subdivision, it became part of Flavia Cæsariensis. The towns possessed by the Cornavii were Deva or Chester, Condate or Kinderton, Banchorium, Banchor, or Bangor, Etocetum or Wall, and Uriconium or Wroxeter; the last of which seems to have been their metropolis. Bangor, Etocetum, and Uriconium are not within the limits of Cheshire. Ormerod mentions a recent discovery of brass tablets, recording a grant of the freedom of the city of Rome to certain troops serving in Britain in the reign of Trajan, A.D. 98—117, some of whom at least may have been stationed near Bickly, where the tablets were found. From inscriptions which have been found, the twentieth legion appears to have continued at Chester as late as the third century, but to have withdrawn long before the final abandonment of the island in the fifth.

On the departure of the Romans, the Britons continued to hold Cheshire until about the year 607, when it was wrested from Brochmael, king of Powys, by the successful arms of Ethelfrid, the Saxon king of Bernicia. Prior to the battle, the Saxon troops are said to have massacred the monks of Bangor, against whom St. Augustine had denounced divine vengeance for their errors, and who aided the Britons with their prayers. Several of the British princes, however, having collected an army and marched to Chester, Ethelfrid was defeated in turn, and this district was not again subjected to the Anglo-Saxon power until about the year 828, when it was taken by King Egbert, and made a part of the kingdom of Mercia. According to Peter Langtoft, Athelwolf held his parliament at Chester after the death of Egbert, and there received the homage of his tributary kings 'from Berwick unto Kent.' About the close of 894, an army of Danes advancing from Northumberland took possession of Chester, and seized the fortress: the Saxons under Alfred, however, having arrived in the vicinity, by destroying the cattle and corn, and intercepting the provisions of the Danes, drove them to such extremities of famine, that they quitted the city and retreated to North Wales. Upon the division of England into three districts by Alfred, Cheshire was included in the Mercian jurisdiction. Cheshire acquired the privileges of a county palatine in the reign of William the Conqueror, who granted it to his nephew, Hugh d'Avranches, commonly called Hugh Lupus, to hold it as freely by the sword as he himself held the kingdom of England by the crown. Lupus created eight barons as soon as he felt himself established in his new dignity, who were bound to attend on him at his court and to furnish him with horses in war. In return for these services, they were invested with the right of holding courts on all pleas, suits, and plaints, and with the power of life and death. The last instance of the exertion of this last privilege occurred in 1597, when the baron of Kinderton's court tried and executed Hugh Stringer for murder. Until the final subjugation of the Welsh, the city of Chester was the usual place of rendezvous for the English army, and the county was exposed to all the evils of a border warfare. In 1237, on the death of John Scot, the seventh earl of Chester of the Norman line, without male issue, Henry III. gave the daughters of the late earl other lands in lieu of the earldom, being unwilling, as he said, to 'parcel out' so great an inheritance 'among distaffs:' the county he bestowed on his son Edward, who did not assume the title, but conferred it on his son Edward of Caernarvon, since which time the eldest sons of the kings of England have always held the title of earls of Chester. The inhabitants of Cheshire took a part in the rebellion of the Percies, and the greater part of the knights and esquires of the whole county, to the number of 200, with many of their retainers, fell in the battle of Shrewsbury, on the 22nd of July, 1403, from which date to the reign of Charles I., Cheshire was not the scene of any important military transactions. From the time of Henry III. to the reign of Henry VIII., the palatinate was governed as independently as it had been by the Norman earls. Henry VIII. however made it subordinate to the crown of England; 'yet,' says Gough, in his 'Additions to Camden,' 'all pleas of lands and tenements and all contracts within the county are to be heard and determined within it; and all determination out of it is deemed void, *et coram non judice*, except in cases of error, foreign plea, and foreign voucher; and for no crime but treason can an inhabitant of this county be tried out of it.' The county being solely under a distinct jurisdiction, and to a certain extent like a separate kingdom, never sent representatives to the English parliament, either for city or shire, until the reign of Edward VI., when, in the year 1549, on the petition of the inhabitants, two members were summoned from each. On the outbreaking of the civil war, as this county was nearly equally divided between the king and the people, the principal persons attempted to preserve its internal peace by a treaty of pacification, which was entered into at Bunbury under the sanction of the commissioners of array, but was rendered nugatory by an ordinance of parliament which required the inhabitants to assist the common cause. The parliament sent Sir William Brereton with a troop of horse, who took possession of Nantwich, which he fortified and made his head-quarters; while Sir Nicholas Byron, on the other side, being appointed colonel-general of Shropshire and Cheshire, and governor of Chester by the king, made it the head-quarters of the royalists. Lord Byron, the nephew of the governor, after successfully reducing several of the parliamentarian garrisons with his Irish regiments, defeated the whole parliamentary forces under Sir William Brereton at Middlewich, in the month of December, 1643. Nantwich, being now the only garrison in Cheshire in the possession of the parliament, was besieged during the greater part of January, 1644, until it was relieved by the united forces of Sir Thomas Fairfax and Sir William Brereton, who defeated Lord Byron and compelled him to retreat with the remains of his forces to Chester on the 25th. Prince

Rupert took Stockport without resistance on the 25th of May; but the royalists were defeated after a severe battle at Castle-heath, near Malpas, on the 25th of August. Next year, on the advance of the king to Chester with a large force, the parliament abandoned all their garrisons, except Tarvin and Nantwich, and, on the 27th of September, the battle of Rowton and Hooleheath was fought near Chester, in which the royalists were defeated; an event which led to the surrender of the garrison of Chester, in February, 1646, and the subjugation of the whole county to the parliament.

In August, 1659, Sir George Booth, having a secret commission from Charles II., appointing him commander-in-chief of all his forces in Cheshire, Lancashire, and North Wales, and being accompanied by several noblemen and gentlemen, appeared in Cheshire at the head of an army of upwards of 3000 men. They mustered on Rowton Heath, and published a declaration that they took up arms to deliver the nation from slavery and obtain a free parliament. The army of the parliament, under General Lambert, met them at Winnington Bridge, near Northwich, on the 16th of August, and soon defeated them. Booth himself, after making his escape from the field in disguise, was taken at Newport Pagnell and sent to the Tower; and Chester, which had been held by Colonel Croxton, surrendered immediately on the approach of the victorious army. The son of Sir George Booth, Lord Delamere, on the eve of the revolution, no sooner heard of the landing of the prince of Orange than he raised a considerable force in Cheshire and Lancashire, declared in his favour, and marched to join him; the Lords Molineux and Aston, with equal promptness, seized Chester for the king; but these warlike preparations were fortunately rendered useless by the abdication.

The Roman roads in the county are found in detached parts: one road, called the Watling-street, was probably more antient than the Roman times. This road enters Cheshire from the north by the ford over the Mersey at Stratford; the marks of the elevated crest, peculiar to the military roads of the Romans, are still visible. A little south-west of Bucklow Hill the roads seem to have divided, the Roman continuing towards Kinderton, and the British pursuing its old direction by Northwich over Delamere Forest, and by Chester to the coast of Caernarvonshire. The Roman road from Manchester to Kinderton crosses the ford of the Mersey, and proceeds to the village of Cross-street. It is seen in the enclosures about Oldfield Hall, and in a field beyond it is still raised several yards. In crossing the adjoining moss it is known by the name of Upcast, whence it runs by Dunham Park to a field called the Harbour-field, in the parish of Kinderton, which is the supposed station of *Condate*. Part of the Via Devana crossed the county from the S.E. to Chester. Besides these, antiquarian conjecture has pointed out several other Roman roads, but the evidence is not so satisfactory in their favour as in the cases of the roads we have traced. That there was a Roman station at Chester is universally admitted —the sites of the others are uncertain.

Besides the castle at Chester, which was built by William the Conqueror, and is now converted into the county-hall, jail, and barracks, there are several others. Beeston Castle, built in 1220, by Randle Blundeville, Earl of Chester, is upon the slope and summit of a sandstone rock, which forms on one side an almost perpendicular precipice of great height. The outer court is irregular in form, inclosing an area of about five acres. The walls are prodigiously thick, and have several round towers. A deep ditch, sunk in the solid rock, surrounds the keep; which was entered by a drawbridge, opposite two circular watch towers, still remaining. The approach within the great gateway between these towers is by rugged steps cut in the natural rock. Camden speaks of a draw-well, bored to the base of the rock, a depth of 90 yards, and communicating with a brook in the vale below. This castle has been in ruins since the civil war of Charles I., when it was dismantled. The others are Halton Castle, of which very few traces now remain; Aldford Castle, of which the foundations are still traced; Shocklach Castle, of which only some earth-works and a high mount are now to be seen; and Shotwick, which appears from the sketch of it in the British Museum to have had a pentagonal wall, with several circular towers inclosing a lofty square one. There are numerous antient mansion-houses. Smith, in his Treatise on Cheshire, calls this county 'the mother and the nurse of the gentility of England.' Another writer (*Harl. MSS.*, No. 1989) speaks of it as 'the seed-plot of gentry.'

Little Moreton Hall, in the parish of Astbury, is the most remarkable antient mansion in the county. The materials of the house are timber and plaster. The singular ornamental style of this very antient edifice, and the curious glazing of its large bay windows, are well exhibited in the plates of Lysons's *Magna Brit.*; Ormerod's *Cheshire*, vol. iii.; and Britton's *Architec. Antiq.*'

Bramhall Hall, the antient seat of the Davenports, about two miles S.W. of Stockport, resembles that of Little Moreton. Ormerod's work contains a beautiful view of this mansion, vol. iii., p. 400.

Saighton Grange, near Chester, was one of the castellated residences of the Abbot of St. Werburg. (Ormerod, vol. ii., p. 240.)

Doddington Hall, the antient seat of the Delves family, is near the road from Nantwich to London. The modern, large, and sumptuous fabric was erected in 1780 by Samuel Wyat. It stands in a spacious park, and overlooks a fine sheet of water. Poole Hall, in the parish of Eastham, was built in the middle of the sixteenth century, and is one of the most venerable specimens of domestic architecture in this county. The style of the architecture is similar to that of all the antient Cheshire mansions, rising into pointed gables, with numerous large bay windows, and having the approach through a line of stables and cow-houses. Brereton Hall, which is in the style of Esher Place in Surrey, was built by Sir William Brereton, and the foundation stone is said to have been laid by Queen Elizabeth herself. The site is on a rising ground near the river Croke. Among the rich decorations of the interior is a curious painting of Queen Elizabeth in full costume, with chains of jewels hanging down to her waist, and with hair extremely red. Another object of great interest is the painted window, which has since been removed from this mansion to Ashton Hall in Warwickshire. Ormerod (vol. iii., p. 50) has given a large coloured drawing of this window, which contains nine full-length figures; the Saxon earls of Mercia, Leofwine and Leofric, and the seven Norman earls of Chester. They are all represented with hair and beards of a deep yellow. Dutton Hall stands on the ridge of a steep declivity overlooking the Weaver. It is surrounded by a broad and deep moat. The great hall is 40 feet by 20, and the whole edifice is a very sumptuous specimen of the domestic architecture of the sixteenth century. Crewe Hall, the seat of Lord Crewe, is an equally fine specimen of the seventeenth century, having been completed in 1636. It is a quadrangular building of red brick, with battlements and large projecting bay windows. An engraving is given in Ormerod, vol. iii., p. 168, and in Lysons's *Magna Brit.* The sculptured oak ornaments of the interior are curious, as well as the painted-glass window of the chapel. There are many portraits by Lely and others of that time. Britton, in his 'Architectural Antiquities,' has a fine drawing of a staircase in this mansion, remarkable for its form and decorations. The seat of Lord Combermere was an antient Cistercian abbey: it is beautifully situated on the margin of the large mere so called. The original edifice has been almost wholly renewed in the pointed Gothic style. Ormerod, vol. iii., p. 210.

Dunham Massey, the seat of the Earl of Stamford and Warrington, was rebuilt in 1730. It is a very spacious quadrangular building of brick, surrounded with a fine park of lofty old oaks, and is interesting for a curious gallery of paintings by Holbein, Lely, Vandyke, and other old masters. Cholmondeley Castle, the seat of the Marquis of Cholmondeley, is in the township of Cholmondeley, in Broxton hundred. The present magnificent modern edifice was built in 1804, on the site of the antient castle. The style of the architecture is the pointed Gothic; and, in approaching the eminence on which it stands, it has the appearance of an antient Norman fortress. The apartments are adorned with some rare and beautiful paintings. Eaton Hall, the seat of Earl Grosvenor, possesses great architectural grandeur, and resembles Cholmondeley Castle, in the pointed Gothic style. The surrounding park and pleasure grounds are laid out with great picturesque effect. Antient crosses occur at the boundary of Lyme Park, at Sandbach, at Oulton, and at Lymm. The crosses at Sandbach are referred by Lysons to a period not long subsequent to the introduction of Christianity among our Saxon ancestors. The sword of Hugh Lupus, the first Norman Earl of Chester, is preserved in the British Museum.

Statistics.—Population. Cheshire is both an agricultural and manufacturing county; in the first respect it ranked higher in 1811 than in 1831, being at the former date the 31st on the list of agricultural counties, and at the latter date, the 34th. Of 78,940 males, twenty years of age and upwards, inhabitants of Cheshire (in 1831), 23,527 were engaged in agricultural pursuits, and 13,305 in manufactures, or in making manufacturing machinery. Macclesfield Hundred is the principal manufacturing district of the county; in 1831 more than 6000 men were employed in manufacturing cotton and calico; nearly 1000 in the manufacture of silk, and about 5500 in manufacturing cotton and silk promiscuously. In Eddisbury and Northwich Hundreds, about 300 were employed in making salt.

The following summary of the population taken at the last census (1831) shows the number of inhabitants and their occupations in each hundred of the county.

HUNDREDS &c.	HOUSES.				OCCUPATIONS.			PERSONS.			Males, twenty years of age.
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	
Broxton	2,953	3,123	10	88	2,012	604	507	8,201	8,214	16,415	4,087
Bucklow	7,849	8,271	36	280	2,944	3,264	2,063	21,631	21,311	42,942	10,718
Eddisbury	4,917	5,202	13	104	2,623	1,383	1,196	13,622	13,269	26,891	6,492
Macclesfield	21,792	23,454	201	1022	3,048	16,472	3,934	60,033	63,316	123,349	28,272
Nantwich	4,237	4,520	9	134	2,194	1,406	920	11,447	11,625	23,072	5,510
Northwich	7,065	7,473	26	254	1,638	3,757	2,078	19,022	19,127	38,149	9,044
Wirrall	3,296	3,544	66	253	1,458	1,080	1,006	9,537	9,563	19,100	4,570
Chester (city)	4,096	4,628	43	388	355	2,665	1,608	9,635	11,709	21,344	4,797
Macclesfield (town)	4,543	4,740	2	295	125	4,366	249	11,005	12,124	23,129	5,450
Totals	60,748	64,955	406	2818	16,397	34,997	13,561	164,133	170,258	334,391	78,940

The population of Cheshire at each of the four enumerations was:—

	Males.	Females.	Total.	Inc. per Cent.
1801	92,759	98,992	191,751	
1811	110,841	116,190	227,031	18·39
1821	132,952	137,146	270,098	18·99
1831	164,133	170,258	334,391	23·81

Showing an increase between the first and last periods of 142,640 persons, or 74½ per cent., which is 17½ per cent. beyond the general rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of

1801 were	£ 66,627	which was	6s. 11d.	for each inhabitant.
1811 „	114,370	„	10s. 0d.	
1821 „	104,081	„	7s. 8d.	
1831 „	102,572	„	6s. 2d.	

The sum expended for the same purpose in the year ending 25th March, 1834, was 92,640*l.*; and assuming that the population had increased at the same rate of per centage since 1831, as in the ten years preceding that period, the above sum gives an average of 5*s.* 1¾*d.* for each inhabitant. All these averages are below those for the whole of England and Wales.

The sum raised in Cheshire for poor's-rate, county rate, and other local purposes, in the year ending 25th March, 1833, was 141,492*l.* 19*s.*, and was levied upon the various descriptions of property as follows:—

	£.	s.	d.
On land	99,808	18	0
Dwelling-houses	29,416	13	0
Mills, factories, &c.	7,837	18	0
Manorial profits, navigation, &c.	4,429	10	0
	£141,492	19	0

The amount expended was—		
For the relief of the poor	98,572	3
In suits of law, removal of paupers, &c.	7,480	17
For other purposes	37,687	10
	£ 143,740	10

In the returns made up for the year ending March, 1834, the descriptions of property assessed for local purposes are not distinguished; 138,228*l.* 16*s.* was raised in that year, and the expenditure was as follows:—

	£.	s.
For the relief of the poor	92,640	0
In suits of law, removal of paupers, &c.	8,569	12
For other purposes	37,105	18
Total	£ 138,315	10

The saving effected in the sums expended for the relief of the poor in 1834, as compared with the expenditure of 1833, is therefore rather more than 6 per cent.; the second item is, however, greater than that of the preceding year, reducing the whole amount of saving to about 3¾ per cent.

The number of turnpike-trusts in Cheshire, as ascertained in 1829, was 27; the number of miles of road under their charge was 349; the annual income arising from the tolls and parish composition was 16,525*l.*; and the annual expenditure 15,354*l.*

The county expenditure in 1834, exclusive of the relief for the poor, was 41,082*l.* 9*s.* 9*d.*, disbursed as follows:—

	£.	s.	d.
Bridges, buildings, and repairs, &c.	5,179	2	6
Gaols, houses of correction, &c., and maintaining prisoners, &c.	14,037	6	7
Coroner	488	13	0
Lunatic asylums	225	0	0
Expenses of prosecutions	9,570	3	2
„ clerks of the peace	737	14	3
„ conveyance of prisoners before trial	1,441	6	11
„ conveyance of transports	817	10	0
„ apprehending and conveying vagrants	395	19	4
„ high and special constables	628	5	2
„ debt—payment of principal and interest	5,614	9	7
„ miscellaneous	1,946	19	3

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 1675, 2443, and 3862; making an average of 239 annually in the first period, of 349 in the second period, and of 552 in the third period. The numbers of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 377, 356, 398, respectively. Among the persons charged with offences, there were committed for

	1831.	1832.	1833.
Felonies	344	339	379
Misdemeanors	38	39	34

The total number of committals in each of the same years was 399, 403, and 431 respectively of whom

The number convicted was	332	330	367
„ „ acquitted	50	48	46
„ „ discharged by proclamation	17	25	18

At the assizes and sessions (in 1835), 533 persons were charged with crimes in Cheshire; out of which number, 34 were charged with offences against the person, 10 of which were common assaults; 49 for offences against property committed with violence; and 389 for offences against property committed without violence. Of the remaining 61, there were 26 committed for riot, 21 for poaching, 2 for arson, 2 for uttering false money, 6 for perjury and unlawful oaths, 1 for killing and maiming cattle, 1 for forgery, and 2 for keeping disorderly houses. Of those committed, 411 were convicted, and 122 acquitted, or no bills were found against them. The greater part of the punishments awarded to those convicted was very slight: 231 were sentenced to imprisonment for six months or under; 56 for one year or under; 17 for two years, and 1 for three years; 4 were fined, and 7 were discharged on sureties. Of the remaining 95, 18 were sentenced to death, which sentence was commuted to transportation or imprisonment; and 77 were sentenced to transportation for various periods. Of the offenders, 461 were males, and 72 females. Among the whole number, 205 could read and write, 155 could read only, 167 could neither read nor write, and the degree of instruction of 6 could not be ascertained. The proportion of the offenders to the population in 1835 was 1 in 627.

The number of persons qualified to vote for the county members of Cheshire is 10,235, being 1 in 23 of the whole population, and 1 in 5 of the male population above 20 years of age. The expenses of the last election of county members to parliament, were to the inhabitants of the county, 415*l*. 15*s*. 6*d*., and were paid out of the general county rate.

There are ten savings-banks in this county. The number of depositors and amount of deposits on the 20th November, 1832, 1833, 1834, and 1835 respectively, were:—

	1832.	1833.	1834.	1835.
Number of depositors .	8853	9262	10,089	10,985
Amount of deposits .	£327,647	332,483	356,334	381,872

The various sums placed in the savings-banks in 1834 and 1835 were distributed as under:—

	1834.		1835.	
£	Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding 20 .	4,774	£34,140	5,291	£ 36,280
" 50 .	3,005	93,097	3,315	103,075
" 100 .	1,403	96,344	1,517	105,536
" 150 .	526	64,355	531	67,608
" 200 .	315	51,507	288	56,184
Above 200 .	66	16,891	43	13,189
Total .	10,089	£356,334	10,985	£381,872

Education.—The following particulars are obtained from the parliamentary inquiry on education made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant Schools	51		
Number of infants at such schools, ages from 2 to 7 years:—			
Males		547	
Females . . .		629	
Sex not specified		342	
			1518
Daily Schools	845		
Number of children at such Schools, ages from 4 to 14 years:—			
Males		14,210	
Females . . .		11,698	
Sex not specified		4,733	
			30,681
Schools .	896		
Total of children under daily instruction .			32,199
Sunday Schools.	363		
Number of children at such Schools, aged from 4 to 15 years:—			
Males		25,314	
Females		26,831	
Sex not specified		4,827	
			56,972

Assuming that the population between 2 and 15 years increased in the same ratio as the whole of the population between 1821 and 1831, and has continued to increase in the same ratio since, we find that there must have been living in Cheshire (in 1834) 117,243 persons between those ages. A very large number of the scholars attend both daily and Sunday schools; thirty-nine schools, containing 8573 children, are returned from various places as attending both daily and Sunday schools, and there are a still greater number not specified; in what proportion the duplicate entry of children is thus produced is therefore uncertain; but we may conclude that not two-thirds of the children receive instruction.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription		By payments from scholars.		Subs[illegible] ment from [illegible]

Daily Schools	92	3941	61	3,714	663	20,003	29	[illegible]
Sunday Schools	9	877	343	54,985	1	86	10	1024
Total...	102	4824	407	58,900	707	21,189	43	[illegible]

The schools established by Dissenters, included in the above statement, are:—

	Schools.	Scholars.
Infant Schools	..	..
Daily Schools	17	1,303
Sunday Schools	165	28,572
The Schools established since 1818 are:		
Infant and other daily schools .	531	16,686
Sunday Schools	290	44,894

Forty-eight boarding-schools are included in the number of daily schools as given above.

No school in this county appears to be confined exclusively to the children of parents of the established church, or of any other religious denomination. Such exclusion is disclaimed in almost every instance, especially in schools established by Dissenters, together with schools for the children of Roman Catholic parents.

Lending libraries of books are attached to eighty-three schools in Cheshire.

CHE'SNE, ANDRE' DU, born in 1584 in the province of Touraine, became distinguished for his historical and philological erudition, and was one of the most learned men of France in his age. The work for which he is best known is his valuable collection of the oldest French chroniclers 'Historiæ Francorum Scriptores coætanei, ab Gentis Origine usque ad Philippi IV. tempora,' of which he edited 4 vol. fol. and his son, François du Chèsne, edited the 5th after his father's death. He also published: 2. 'Histoire des Rois, Ducs, et Comtes de Bourgogne et d'Arles,' 2 vol. 4to. 3. 'Histoire des Cardinaux Français.' 4. 'Bibliotheca Cheniacensis.' 5. 'Bibliothèque des Auteurs qui ont écrit l'Histoire et Topographie de la France.' 6. 'Histoire des Papes,' 2 vol. fol. 7. 'Histoire généalogique des Maisons de Luxembourg, de Montmorency, Vergy, Guisnes, Châtillon, Béthune, &c.,' 7 vol. fol., besides a History of England in 2 vol. fol., Paris, 1634. Duchesne died in 1640 near Paris. He has been called the father of French history.

CHESS, to adopt the definition of Dr. Johnson, is 'a nice and abstruse game, in which two sets of men are moved in opposition to each other.' The best method of learning the names of the pieces, with their moves, and the manner of placing them at the beginning of the game, is to take an hour's lesson from a friend; and we will therefore pass over this part of the alphabet of the game, to make room for more interesting matter; premising, however, two points which are often unknown to drawing-room as distinguished from club-players. The first is, that though every pawn may be moved two squares at its first move, it may be taken by any pawn which could have taken it, had it moved but one square: and the pawn in such case is said to be taken en *passant*. Thus, suppose the white queen's bishop's pawn to have advanced to the adversary's queen's bishop's fourth square, and the black queen's knight's pawn to be at its own square: if the black should move his queen's knight's pawn two squares, the white may take it with his queen's bishop's pawn, and the white pawn is placed at the black queen's knight's third square, just as if the black pawn had been moved one square only. The second point is, that when a pawn has reached the last square on the adverse side of the board, it becomes a queen, rook, bishop, or knight, as the player to whom it belongs may choose; nor is this privilege limited, as common players often suppose, to cases where the first queen or a rook, &c., has been lost.

Notation used in chess. The board is supposed to be divided into two equal parts, one of which belongs to the white, the other to the black player. The square on which the king stands is called the king's square; the one in front of it the king's second square, the next in front of that the king's third square; then the next the king's fourth square; the next again is called the king's fifth square, or the adversary's king's fourth square, and so on. The bishop standing next to the king is called the king's bishop; the square on which it stands the king's bishop's square; the next square in front is the king's bishop's second square, and so on. In like manner we have the king's knight's square, the king's rook's square, the queen's square, the queen's bishop's square, the queen's knight's square, and the queen's rook's square; and each master-piece gives its name to the other squares on its file. The pawns too take their names from the pieces before which they stand, and are called the king's pawn, the queen's pawn, the king's bishop's pawn, the king's rook's pawn, &c. Suppose we wished to describe a situation in which the queen's pawn was in its original position; we might say that it was at its square, or at queen's second square. If it had been moved one square, we might say that it was at its third square, or at the queen's third square; the former phrase is not strictly accurate, but is sanctioned by the best writers.

This notation, however, is commonly employed in a more compendious form; thus K. stands for king, Q. for queen, R. for rook, B. for bishop, Kt. for knight, P. for pawn, sq. for square, adv. for adversary's, chg. for checking; observing K. may stand for king's as well as king, Q. for queen's, &c. Q. Kt. stands for queen's knight, Q. Kt. P. for queen's knight's pawn, and so on.

There is another method of notation frequently employed by continental writers, which consists in using the first eight letters of the alphabet to designate the eight files, and the first eight figures to designate the squares of those files; thus P. E. 4 means that the player of the white pieces has moved his king's pawn two squares, and P. E. 5 denotes the same move for the black. This notation is shorter than even the most abbreviated form of the first-mentioned one; but it is perplexing and difficult to follow, from its being based on a less natural division of the board.

We may here observe that the ranges of squares running from right to left are called *ranks*, and those running from one player to the other are called *files;* the lines sloping obliquely across the board are termed *diagonals*.

TECHNICAL TERMS. *Castling*. This is a combined move of the king and rook, which is allowed once in the game. The method of castling is as follows: first, with the K. R., the R. must be placed on the K. B. square, and the K. at K. Kt. square; secondly, with the Q. R., the R. must be placed on the Q. square, and the K. on Q. B. square. The space between the king and rook must be unoccupied; neither the king nor the rook must have moved; and the squares over which the king moves must not be attacked at the time by any adverse piece.

Check signifies an attack made on the king by a piece or pawn. A *check by discovery* is when the king is attacked not by the piece that moves, but by one which is behind it; for example, place the white king at his own square, black queen at her king's square, and a black knight at adv. king's third square; by playing the knight to adv. king's knight's fourth square, you give *check by discovery* with the queen; if you play the knight to adv. queen's bishop's second sq., or king's knight's second sq., you give *double check*.

A perpetual check consists in an alternation of checks, from each of which the adverse king escapes only to be subjected to the other. Thus suppose the pieces to be in the following situation:—

Black.	*White.*
K. at K. Kt. sq.	K. at K. R. sq.
P. at K. Kt. 2 sq.	Q. at K. sq.
Q. at adv. Q. R. 2 sq.	
R. at adv. Q. R. 3 sq.	

In this critical position, white having the move can draw the game by checking at adv. K. sq., and then at adv. K. R. fourth sq., and again at adv. K. sq., and so on *ad infinitum*.

Checkmate. When the king is attacked and cannot move out of check, take the piece that checks him, or interpose any piece, he is said to be *checkmated*, and the game is won by the player who gives the *checkmate*. In other words, when the king is so attacked that he would inevitably be taken, if he were not king, he has lost the game.

Doubled Pawn. When two pawns of the same colour are on the same file, the more advanced one is called a doubled pawn; thus if there is a pawn on K. R. second sq., and another on K. R. third sq., the latter is called a doubled pawn.

Drawn Game. When neither party can checkmate the other, the game is drawn. This may happen in many ways; first, if the force remaining on the board is not sufficient to checkmate, as if you have only your king and a bishop, or a knight, or both knights, against the adverse king; secondly, when you have sufficient force, but are unable to checkmate with it: the twenty-second law in Lewis's 'Elements' bears upon this point, and is as follows—'As the game is drawing to a conclusion, if one of the players remain with a rook and bishop against a rook, with both bishops, or with a knight and bishop against a king, he must checkmate his adversary in fifty moves on each side at most; for if at the expiration of fifty moves checkmate be not effected, the game must be considered as drawn,' &c. &c.* Thirdly, by a perpetual check on the adverse king; fourthly, when both players act on the defensive, and abstain from attacking the adversary; fifthly, when both players have an equal but small force, as a rook or queen; and sixthly, when one of the kings is stalemated.

Exchange—To gain the. When a player obtains a rook for a bishop or knight, he is said to gain the exchange, a rook being more valuable than a knight or a bishop.

Gambit. This word is derived from the Italian *gambetto*, a tripping up of the heels; the King's Gambit begins in the following manner:

White.	*Black.*
1. K. P. 2 sq.	1. K. P. 2 sq.
2. K. B. P. 2 sq.	

If black abstains from taking the offered pawn, he is said to refuse the gambit.

The following moves constitute the Queen's Gambit:

White.	*Black.*
1. Q. P. 2 sq.	1. Q. P. 2 sq.
2. Q. B. P. 2 sq.	

Stamma, a native of Aleppo, who published a good analysis of this opening, called it the gambit of Aleppo, an appellation which was afterwards adopted by Philidor.

The sacrifice of the knight in the following manner constitutes the Muzio Gambit, which is perhaps the most brilliant opening hitherto invented:

Black.	*White.*
1. K. P. 2 sq.	1. K. P. 2 sq.
2. K. B. P. 2 sq.	2. P. takes P.
3. K. Kt. to K. B. 3 sq.	3. K. Kt. P. 2 sq.
4. K. B. to Q. B. 4 sq.	4. K. Kt. P. 1 sq.
5. Castles.	5. K. Kt. P. takes Kt.

The Salvio and the Cunningham Gambit are likewise varieties of the King's Gambit. The Lopez Gambit, in which the K. B. P. is not sacrificed until the fourth or fifth move, begins in the following or some similar manner:

White.	*Black.*
1. K. P. 2 sq.	1. K. P. 2 sq.
2. K. B. to Q. B. 4 sq.	2. K. B. to Q. B. 4 sq.
3. Q. to K. 2 sq.	3. Q. P. 1 sq.
4. K. B. P. 2 sq.	

In the Bishop's Gambit, the first player moves K. B. to Q. B. 4th square at his third move, instead of K. Kt. to K. B. 3rd square.

Minor Piece is an appellation common to the bishop and knight.

Passed Pawn. A pawn is called *passed* when it is no longer obstructed by any adverse pawn on its own file, or either of the adjoining ones.

Stalemate. This name is given to the termination of the game, when the player whose turn it is to move has his king so placed, that though not in check he cannot move without going into check, and there is nothing else to play. The game is then drawn. It was formerly the law among English players, that the player whose king was stalemated won the game, and many uninstructed players imagine this to be the case still; but the rule has long since been altered, with great propriety. The following is an example of a stalemate:

* Of the checkmates mentioned in the text, that with the bishop and knight is remarkably difficult; that with the two bishops very easy; and that with rook and bishop against rook uncertain. Philidor asserted that it could always be forced; but succeeding writers, among whom we may mention Mr. Lewis (*Chess Lessons*, vol. ii. p. 304), believe that in any indifferent position the game is drawn.

White.	*Black.*
1. K. at K. R. sq.	1. K. at K. R. sq.
	2. Q. at adv. K. B. 2 sq.

White has the move, and is consequently stalemated.

This is the case likewise in the following position :

White.	*Black.*
1. K. at K. R. sq.	1. K. at K. R. sq.
2. B. at K. R. 2 sq.	2. Q. at adv. K. B. 2 sq.
	3. R. at K. R. 2 sq.

White is to move; he cannot move the king without going into check of the queen, nor can he move the bishop without exposing himself to check of the rook ; he is consequently stalemated. The student who is desirous of seeing remarkable positions where the game is drawn by stalemate, will find them in Lewis's edition of *Sarratt*, pp. 108, 111, 152, 153, 154, 172; in Lewis's *Stamma*, situations 97, 98, 99, 100; and in Lewis's *Chess Problems*, situations 89 and 95.

The following games will exemplify many of the preceding laws and definitions ; the fourth is one of the match games played between the London and Edinburgh clubs, in the years 1824—28 :

Game 1 (*Fool's Mate*).

Black.	*White.*
1. K. B. P. 1. sq.	1. K. P. 2 sq.
2. K. Kt. P. 2 sq.	2. Q. to adv. K. R. 4 sq. Checkmating.

Game 2 (*Scholar's Mate.*)

White.	*Black.*
1. K. P. 2 sq.	1. K. P. 2 sq.
2. K. B. to Q. B. 4 sq.	2. K. B. to Q. B. 4 sq.
3. Q. to adv. K. R. 4 sq.	3. K. Kt. to K. B. 3 sq.
4. Q. takes K. B. P. Checkmating.	

Black's third move ought to have been Q. to K. second square.

Game 3 (*A Gambit from Greco*).

White.	*Black.*
1. K. P. 2 sq.	1. K. P. 2 sq.
2. K. B. P. 2 sq.	2. K. P. takes P.
3. K. Kt. to K. B. 3 sq.	3. K. Kt. P. 2 sq.
4. K. B. to Q. B. 4 sq.	4. K. B. P. 1 sq.
5. K. Kt. takes K. Kt. P.	5. P. takes Kt.
6. Q. to adv. K. R. 4 sq. chg.	6. K. to his 2 sq.
7. Q. takes K. B. P. and checks.	7. K. to his sq.
8. Q. to adv. K. R. 4 sq. chg.	8. K. to his 2 sq.
9. Q. to adv. K. 4 sq., and checkmates.	

Black's fourth move was a very bad one ; he ought to have played either K. B. to K. Kt. 2 square, or K. Kt. P. 1 square: having committed this mistake, however, he should have played K. R. P. 2 squares at his fifth move, instead of taking the Kt. The pawn which white takes at his 7th move, having been just before on the bishop's file, retains the name of K. B. P., though it might also be called K. Kt. P. If black at his 7th move were to interpose K. Kt., white would checkmate on the move by playing Q. to adv. K. 4th sq.

Game 4.

London.	*Edinburgh.*
White	*Black.*
K. P. 2 sq.	1. K. P. 2 sq.
2. K. Kt. to K. B. 3 sq.	2. Q. Kt. to Q. B. 3 sq.
3. Q. P. 2 sq.	3. K. P. takes P.
4. K. B. to Q. B. 4 sq.	4. K. B. to Q. B. 4 sq.
5. Q. B. P. 1 sq.	5. Q. to K. 2 sq
6. K. castles.	6. P. takes P.
7. Q. Kt. takes P.	7. Q. P. 1 sq.
8. Q. Kt. to adv. Q. 4 sq.	8. Q. to her 2 sq.
9. Q. Kt. P. 2 sq.	9. Q. Kt. takes P.
10. Q. Kt. takes Kt.	10. K. B. takes Kt.
11. K. Kt. to adv. K. Kt. 4 sq.	11. K. Kt. to K. R. 3 sq.
12. Q. B. to Q. Kt. 2 sq.	12. K. to K. B. sq.
13. Q. to Q. Kt. 3 sq.	13. Q. to K. 2 sq.
14. K. Kt. takes K. B. P.	14. K. Kt. takes Kt.
15. Q. takes K. B.	15. K. Kt. to K. 4 sq.
16. K. B. P. 2 sq.	16. Kt. takes K. B.
17. Q. takes Kt.	17. Q. to K. B. 2 sq.
18. Q. to Q. B. 3 sq.	18. Q. B. to K. 3 sq.
19. K. B. P. 1 sq.	19. Q. B. to adv. Q. B. 4 sq.
20. K. R. to K. B. 4 sq.	20. Q. Kt. P. 2 sq.
21. K. P. 1 sq.	21. P. takes P.
22. Q. takes P.	22. K. R. P. 1 sq.
23. Q. R. to K. sq.	23. K. R. to K. R. 2 sq.
24. K. B. P. 1 sq.	24. K. Kt. P. 2 sq.
25. K. R. to adv. K. B. 4 sq.	25. Q. R. P. 2 sq.
26. Q. to adv. Q. B. 4 sq. chg.	26. K. to K. Kt. sq.
27. K. R. takes P. chg.	27. P. takes R.
28. Q. takes P. chg.	28. K. to K. B. sq.
29. B. to Q. 4 sq.	29. B. to K. 3 sq.
30. Q. to adv. Q. B. 4 sq. chg.	30. K. to K. Kt. sq.
31. Q. to adv. K. Kt. 4 sq. chg.	31. K. to K. B. sq.
32. Q. B. checks.	32. K. to his sq.
33. Q. to adv. Q. 4 sq.	33. Q. R. to its 3 sq.
34. Q. to adv. Q. Kt. 2 sq.	34. Q. to K. R. 4 sq.
35. K. B. P. checks.	35. K. takes P.
36. R. to K. B. sq. chg.	36. K. to Kt. 3 sq.
37. Q. to K. 4 sq. chg.	37. Bishop interposes.
38. Q. to adv. K. sq. chg.	38. Rook interposes.
39. Q. to adv. K. Kt. sq. chg.	39. K. to K. B. 3 sq.
40. K. Kt. P. 2 sq.	40. Q. R. to its sq.
41. Q. takes Q. R.	41. Q. takes P. chg.
42. K. to K. R. sq.	42. R. to Q. 2 sq.
43. B. to Q. R. 3 sq.	43. K. to K. B. 2 sq.
44. Q. to adv. Q. B. 3 sq.	44. R. to adv. Q. sq.
45. Q. takes Q. Kt. P.	45. Q. to adv. K. 4 sq. chg.
46. K. to K. Kt. sq.	46. K. to K. Kt. 3 sq.
47. Q. to Q. Kt. 2 sq.	47. Q. to adv. K. Kt. 4 sq. chg.
48. Q. to K. Kt. 2 sq.	48. Q. takes Q. chg.
49. K. takes Q.	49. B. to adv. K. R. 3 sq. chg.
50. K. takes B.	50. R. takes R.
51. B. to adv. K. 2 sq.	51. Q. R. P. 1 sq.
52. Q. R. P. 1 sq.	52. R. to K. B. 4 sq.

The London club resigned the game.

The London club had the game in their hands until the unfortunate though ingenious sacrifice of the rook at the twenty-seventh move. They might have won, at the twenty-fourth move, by checking with Q. at adv. Q. B. 4 sq., and then playing Q. R. to adv. K. 2 sq., as Mr. Lewis has demonstrated in his excellent edition of the match games, p. 30, *et seq.*: or they might have won at the twenty-sixth move, by playing B. to Q. 4 sq., as Mr. Lewis has shown in his 'Remarks on the Report of the Committee of the Edinburgh Chess Club,' p. 7, *et seq.* Even after the sacrifice of the rook, London might have drawn the game by a perpetual check, by checking again with Q. at adv. Q. B. 4 sq., at the 32 move, and then at adv. K. Kt. 4 sq., &c.

History and Literature of the Game. The game of chess is of great antiquity, and appears to have been invented in China or Hindostan. Sir William Jones inclines to the latter supposition. In the second volume of the 'Asiatic Researches,' he says, 'We may be satisfied with the testimony of the Persians ; who, though as much inclined as other nations to appropriate the ingenious inventions of a foreign people, unanimously agree that the game was imported from the west of India in the sixth century of our æra. It seems to have been immemorially known in Hindostan by the name of *Chaturanga*, *i. e.*, the four *angas*, or members of an army ; which are these, elephants, horses, chariots, and foot-soldiers ; and in this sense the word is frequently used by epic poets in their descriptions of real armies. By a natural corruption of the pure Sanscrit word, it was changed by the old Persians into *chatrang* ; but the Arabs, who soon after took possession of their country, had neither the initial nor the final letter of that word in their alphabet, and consequently altered it further into *shatranj*, which found its way presently into the modern Persian, and at length into the dialects of India, where the true derivation of the word is known only to the learned. Thus has a very significant word in the sacred language of the Brahmins been transformed by progressive changes into *axedraz*, *scacchi*, *echecs*, *chess* ; and by a whimsical concurrence of circumstances has given birth to the English word *check*, and even a name to the *exchequer* of Great Britain.' He speaks also of 'the *rat'h*, or armed chariot, which the Bengalese pronounced *rot'h*, and which the Persians changed into *rokh*, whence came the *rook* of some European nations ;

as the *vierge* and *fol* of the French are supposed to be corruptions of *ferze* and *fil*, the prime minister and elephant of the Persians and Arabs.'

It is perfectly clear that chess was not known to the Greeks or Romans; indeed it is commonly supposed not to have been introduced into Europe till the time of the Crusaders; though there is a set of Latin verses in Hyde, describing the game, which is said to have been written during the time of the Saxons, and therefore a good number of years before the first crusade. Several points in which the eastern game now differs from ours were then observed in Europe. The following are the peculiarities of the Hindostanee game, as given by a native player:

'1. In the Hindostanee game the king is placed to the right hand, so that the king of one party is opposite the queen of the other.

'2. There are three modes of winning the game. The first called Boorj, when the losing party has no piece left on the board—the game is then discontinued. This mode of winning is reckoned the least creditable, and in many parts it is deemed a drawn game. The second is by checkmate with a piece, when the losing party must have one or more pieces remaining. The third is by checkmate with a pawn (pied-mât), the losing party having one or more pieces remaining. This last shows the greatest superiority.

'3. Stalemate is not known in the Hindostanee game; if one party get into that position the adversary must make room for him to move. In some part of India he that is put in this predicament has a right to remove from the board any one of the adversary's pieces he may choose.

'4. No party can make a drawn game by an universal [perpetual] check; he that has the option must adopt some other move.

'5. The pawns on reaching the last square of the board are transformed into the master piece of that file, except the king's pawn, which becomes a queen. If the pawn be on the knight's file, the knight immediately on being made takes one move in addition to the last move of the pawn, unless some other piece command the square to which the pawn was advancing.

'6. No pawn can be pushed up to the last square of the board, nor take any piece on that line, so long as the master piece of that file remains.

'7. The king does not castle, but is allowed the move of a knight once in the game, not however to take any piece—nor can he exercise this privilege after having been once checked.

'8. The two royal pawns and those of the two rooks are allowed to move two squares each at first, so long as their pieces remain at their squares. The other pawns move only one square at a time.

'9. At the beginning of a game, four or eight moves, as may be determined, are played up on both sides. This in a great measure prevents unnecessary exchanges till a general disposition is adopted and the pieces brought out.

'10. The first move at the beginning of a match is arbitrary; afterwards he that has won most games moves first.' (*Essays on Chess, adapted to the European mode of Play; consisting principally of Positions or critical Situations, calculated to improve the Learner and exercise the Memory.* By Trevangadacharya Shastree. Translated from the original Sanscrit. Bombay. 1814.)

In the Latin verses above mentioned, the queen is directed to be placed on the right hand of the king, and therefore the queen of one party will be opposite the king of the other, as in India.

'Rex paratus ad pugnandum, primum locum teneat,
Ejus atque dextrum latus Regina possideat.'

Other peculiarities mentioned by Trevangadacharya Shastree are found in the older European writers. Thus he says that the king does not castle; and there is no example of castling in Sarratt's translation of 'Damiano.' Again, the king once in the game may move like a knight; and we find instances of this singular privilege in Sarratt's 'Ruy Lopez,' p. 97; in his 'Gianutio,' p. 5; and in his 'Gustavus Selenus,' p. 41.

Other Hindostanee modes are still preserved at Stroebeck, a village of chess-players near Halberstadt, of which Mr. Lewis has given a very interesting account. Our Indian tells us that four or eight moves are played up on each side; and in one of his games the same moves are played by both parties seventeen times! At Stroebeck, in like manner, 'The pieces being placed as usual, each party is obliged to play his king's rook's pawn, queen's rook's pawn, and queen's pawn two squares, and the queen to her third square.' (Lewis's *Chess Lessons*, second series, p. 416.) And as in India, the privilege of moving two squares is restricted to the pawns of the king, queen, and rooks, so at Stroebeck it is confined to those of the queen and rooks. At Stroebeck too castling is not allowed, but Mr. Lewis was informed that some players have lately permitted it.

The villagers possess a chess-board which was presented to them by the elector of Brandenburg, on the 13th of May, 1651; 'on the other side the board is divided into 96 squares (12 by 8); this is intended for the courier game, which is played with the usual chess-men, to which are added, for each player, four pawns, two couriers, a man, and a fool, which last two are now called state counsellors.' (Lewis's *Chess Lessons*, second series, p. 414.)

In this game, which has been played at Stroebeck from time immemorial, another one of the antique rules of chess appears to be preserved. In the courier game the move of the bishop is confined to the second square from the one on which he stands; thus, a bishop placed on the king's 4 sq. can be played only to K. Kt. 2 sq., Q. B. 2 sq., Q. B. 6 sq., or K. Kt. 6 sq.; and in the Latin verses above quoted, we are told that 'Cædit calvus per transversum tertiam ad tabulam,' that is to say, 'the bishop attacks the third square in an oblique direction;' the square on which he stands being included in the three, according to the old way of reckoning; just as Damiano, for instance, talks of a pawn moving *three* squares; and Mr. Lewis, adopting this mode, speaks of the bishop's move in the courier game, being limited to *three* squares.

The reader who is inclined to investigate the history of Chess may consult Hyde's treatise, 'Mandragorias, seu Historia Shahiludii. Oxoniæ, 1694;' 'Leibnitzii, Annotatio de quibusdam Ludis,' &c., in 'Misc. Soc. Reg. Berol.,' t. i., an. 1710: the historical disquisition on the game of Chess, by Daines Barrington, in the 9th vol. of the 'Archæologia;' Sir William Jones's 'Essay,' in the 2nd vol. of the 'Asiatic Researches;' and a paper, by Mr. Eyles Irwin, in the 'Transactions of the Royal Irish Academy.' Twiss's work, entitled 'Chess,' 2 vols., 8vo., is an amusing repertory of anecdotes of chess-players, accounts of chess-books, and passages relating to the game, extracted from an infinity of authors.

Jacopo Dacciesole, a Dominican friar, wrote a treatise on Chess before the year 1200, entitled 'Solatium Ludi Scacchorum, scilicet Libellus de Moribus Hominum et Officiis Nobilium.' This was a book of great reputation for several centuries. Caxton's work on Chess, printed in 1474, was a translation from a French translation of Dacciesole's Treatise. The object of the writer however is rather to teach morals than Chess; he merely gives the moves, and then treats of the duties of the various ranks represented by the chess-men. Thus, in Caxton, 'The thirde chapitre of the seconde tractate treteth of the alphyns, ther offices, and mahers. The alphyns ought to be made and formed in manere of juges syttynge in a chayer, with a book open to fore their eyen,' &c.

And then comes an account of the offices of these judges, one of whom is supposed to sit in criminal, and the other in civil cases. The alphyn, we may remark, is the bishop.

Catalogue of chess writers in chronological order:—

The earliest practical writer on Chess is Lucena, whose treatise came to light only a few years since. It is entitled 'Arte breue, e introduccion muy necessaria para saber jugar al Axedres, con ciento y cincuente Juegos de partido.' Salamanca, 4to., about 1495.

His book was copied by Damiano, who published a treatise at Rome in 1512, entitled 'Libro da imparare giuocare a Scacchi,' &c., 4to. There is another edition, printed at Rome in 1524[*].

Ruy Lopez. 'Libro de la invencion liberal y arte de juego del Axedres, &c. En Alcara de Henares,' 1551, 4to.

Gianutio (Horatio). 'Libro nel quale si tratta della maniera di giuocar a' Scacchi, con alcuni sottilissimi partiti.' Turino, 1597. 4to.

---

[*] It is a curious fact in literary history, that Damiano's work was in its turn copied without acknowledgment; in the quaint language of Bingham's translation of Ponziani, 'Of the eighty-eight parties by this author [Damiano] nine or ten are very ingenious, not so the others. We, nevertheless, must believe, that all alike excessively struck the fancy of D. Antonio Porto, who, with admirable frankness, caused them to be-reprinted under his own name, without adding the smallest particle to them himself; as may be seen by the two editions, one printed at Bologna, by Gio. Rossi, in 1606, the other at Venice, by Peter Farri, in 1619.' p. 63.

Salvio (Alessandro). 'Trattato dell' invenzione e dell' arte liberale del giuoco degli Scacchi.' Nap. 1604, 1612, 1618; e diviso in lib. vj., per Gio. Dom. Montanaro, 1634. 'Discorso sopra il giuoco degli Scacchi con la sua Apologia contro il Carrera,' 1634, 1723. 4to.

———'Il Puttino, ossia il cavaliere errante sopra il giuoco de' Scacchi,' &c. Nap. 1634. 4to.

Selenus (Gustavus.) 'Das Schach oder Koenig-Spiel. Lips.,' 1616, folio. (This book was written by the duke of Brunswick.)

Greco (Gioachino). 'Trattato di nobilissimo e militare esercitio de' Scacchi.' (We do not know the date of this work, but that of the earliest French translation is 1615.)

Carrera (Pietro). 'Del giuoco degli Scacchi,' &c. Militelli, 1617. 4to.

Bertin (Capt.) 'The noble game of Chess.' London, 1735. 12mo.

Stamma (Philippe). 'Essai sur le jeu des Échecs,' &c. Paris, 1737. 12mo.

Philidor (A. D.) 'Analyse du jeu des Échecs,' &c. Londres, 1749. 8vo.

Rio (Ercole Del). 'Osservazioni pratiche sopra il giuoco degli Scacchi.' 4to. Modena, 1750. (This is the celebrated anonymous Modenese.)

Lolli (Giamb). 'Osservazioni teorico-pratiche sopra il giuoco degli Scacchi.' Bologna, 1763. Folio.

Cozio (il Conte Carlo). 'Il giuoco degli Scacchi.' Torino, 1766. 2 vols., 8vo.

Ponziani (Domenico Canonico). 'Il giuoco incomparabile degli Scacchi,' &c. Modena, 1769. 4to. There is an English translation of this work by Bingham.

'Traité théorique et pratique du jeu des Echecs, par une société des amateurs.' Paris 1775 and 1786.

'Les Stratagèmes des Echecs,' 2 tom. 16mo. Paris. An. X. There is an English translation of this work by Kenny.

Allgaier. 'Neue theoretisch-practische Anweisung zum Schachspiele.' 8vo. Wien, 1811.

Koch (J. F. W.) 'Codex der Schachspielkunst.' 2 vols., 8vo. Magdeburg, 1813.

Sarratt (J. H.) 1. 'Treatise on the game of Chess.' 2 vols., 8vo. London, 1808.

2. 'Translation of the works of Damiano, Ruy Lopez, and Salvio, on the game of Chess.' 8vo. London, 1813.

3. 'Translation of the works of Gianutio and Gustavus Selenus.' 2 vols., 8vo. Lond., 1817.

4. 'New Treatise on the game of Chess,' upon a plan of progressive improvement hitherto unattempted. 2 vols., 8vo. Lond., 1821.

Trevangadacharya Shastree. 'Essays on Chess, adapted to the European mode of play,' &c. Bombay, 1814.

'A selection of fifty games, played by the automaton chess-player.' London, 1820. (Pawn and move are given by the automaton in all these games.)

Cochrane. 'A Treatise on the game of Chess; containing the games on odds, from the "Traité des Amateurs;" the games of the celebrated anonymous Modenese; a variety of games actually played; and a catalogue of writers on Chess.' Lond. 8vo. 1822.

Silberschmidt. 'Das Gambit, oder Angriff und Vertheidigung gegen Gambitzüge,' &c. Brunswick, 1829. 8vo.

Mauvillon. 1. 'Anweisung zur Erlernung des Schachspiels,' &c. Essen, 1827. 8vo.

2. 'Belehrende Unterhaltung für junge angehende Schachspieler,' &c. Essen, 1831 and 1832. 16mo.

Lewis (Wm.) 1. 'Oriental Chess, or Specimens of Hindostanee excellence in that celebrated game.' 2 vols. Lond., 1817.

2. 'Stamma on Chess,' with notes. 8vo. Lond., 1818.

3. 'Greco on Chess,' with notes. 8vo. Lond., 1819.

4. 'Sarratt on Chess,' with notes. 8vo. Lond., 1822.

5. 'Elements of the game of Chess.' 12mo. Lond. 1822.

6. 'Chess Problems.' 12mo. Lond., 1827.

7. 'The Games of the Match at Chess played by the London and the Edinburgh Chess Clubs, with numerous variations and remarks.' 8vo. Lond., 1828.

8. 'Remarks on the Report of the Committee of the Edinburgh Chess Club.' 8vo. Lond., 1829.

9. 'A Series of Progressive Lessons on the game of Chess.' 8vo. London, vol. i., 1831, vol. ii., 1832.

10. 'A Selection of Games at Chess, played at the Westminster Chess Club, between Monsieur L. C. de la Bourdonnais and an English amateur of first-rate skill, with remarks.' 8vo. London, 1835.

11. 'Chess for beginners.' London, 1835.

Mr. Lewis has likewise published a very valuable translation of Carrera.

'The Games of the Match at Chess, &c., as reported by the Committee of the Edinburgh Chess Club.' Edinburgh and London, 1829. 8vo.

Walker (George). 1. 'Variations on the Muzio Gambit.' London, 1831. 12mo.

2. 'A New Treatise on Chess.' London, 1832; second edition, 1833, small 8vo.

3. 'A New Translation of Philidor's Analysis.' London, 1832, royal 18mo.

4. 'A Selection of Games at Chess, actually played by Philidor and his contemporaries, now first published from the original MSS., with notes,' &c. London, 1835, small 8vo.

5. 'Chess made Easy.' London, 1836.

Walker (W. Greenwood.) 'A selection of games at Chess actually played in London, by the late Alexander Mc Donnell, Esq.,' &c. London, 1836. 12mo.

CHESTER, an antient and celebrated city of England, on the River Dee, near to where it falls into an æstuary of the Irish Channel.

In nothing is the impression of the Roman possession of this island more observable than in the names of so many considerable places, into which this word *Chester*, which is the Latin *Castrum* or *Castra*, enters; Manchester, Ribchester, Grantchester, &c. Sometimes it appears in the form of *Caster*, as Doncaster, Tadcaster. It is sometimes much contracted, as in Manceter, Exeter, Wroxeter. It occurs here without any prefix, but antiently this city was often called West Chester. There are other Chesters and Castors.

It might be inferred from the name alone that these were originally military stations. But Chester does not depend on etymology alone for proof of its Roman origin, or of its having been the station of a part of the Roman army. The distribution of the streets, the two main thoroughfares cutting one another at right angles in the centre of the city, is Roman. There is reason to conclude that the fortifications of the city are on a Roman basis. Some remains of Roman masonry have been discovered; and Chester has produced innumerable coins, fibulæ, inscribed tiles, inscribed stones and altars, the usual vestiges of the Romans. The most important discovery of this kind was made in 1653, when a votive altar to Jupiter Tanarus was dug up, which had been raised by an officer of the twentieth Legion called the Victorious. Other traces of this particular Legion have been found at Chester, confirming what we find in Antonine's Itinerary, that at *Deva* (which is evidently the Dee, meaning the station on the Dee, as Doncaster is in the same Itinerary mentioned as Danum, the Don, the river on which it is situated) the twentieth Legion had its station. The Welsh name of Chester has reference to the same fact, being, when rendered into English, the City of the Legion on the waters of the Dee.

Chester had, in the middle ages, several historical writers of its own, as Roger called De Cestria, Ralph Higden, and Henry Bradshaw. We pass over their traditionary stories of the antiquity and origin of their city as undeserving regard, and consider what has now been related as the sufficient and the true account of the origin of this city. We might, if our limits would allow, pursue the inquiry further, and ask why the Romans fixed upon this point as the permanent station of one of their legions, and at what period of their possession of Britain this was done. The Messrs. Lysons conceive that the original castrum was constructed by Ostorius Scapula soon after the defeat of Caractacus.

Chester was evidently the most considerable place in a large tract of country in the Roman times, and so continued when the Romans had withdrawn their forces. The possession of it was an object of importance to the Saxons and to the remains of the Britons. The two nations seem to have possessed it by turns, and it was certainly one of the last, if not the last, of the places which yielded to the Saxon power. In the Saxon Chronicle we are told that Ethelfrid, king of Northumbria, took it from the Britons in A.D. 607. After that date it was in the hands of the Britons, who held councils in it for political purposes. Finally, in A.D. 830, it fell under the power of Egbert.

From that period to the Conquest, 1066, Chester is often mentioned in the annals of the Saxon sovereignty, and its own annalists have delighted to record that King Edwin was one day rowed by six kings (no doubt small Welsh princes) on the waters of the Dee. Its situation as a frontier fortress against Wales necessarily gave it importance; but it had also a consequence as a place of security for the inhabitants of the coast when they were menaced with invasion from the Danes and Northmen.

The circumstance which we have just mentioned was the cause of one of the most important events in the history of Chester. On one occasion, when a descent from the Danes was apprehended, the body of Saint Werburgh, a Saxon saint, daughter of Wulphere king of Mercia, which had been preserved as a sacred relic, was removed for security to Chester. This was in A.D. 875. These relics remained at Chester. No doubt some kind of Christian community existed at Chester before this circumstance occurred: but from this time Saint Werburgh became the tutelar saint of Chester; a religious community was founded, among whom she was held in especial honour, and in whose church her relics were sumptuously enshrined. The house continued to flourish through a period of six centuries and a half, one of the wealthiest of the monastic establishments of England, its annual revenues exceeding 1000*l*., when at the Reformation it was dissolved with the other foundations of its class.

Chester had also in the Saxon times a peculiar local government, and peculiar municipal customs, of which there is a large and particular account in 'Domesday Book.' The number of the rated houses was 431. It had its trade by sea and its home trade; and there is reason to believe that associations of the members of particular trades, which have flourished longer at Chester than in most other places, had their origin in Saxon times, and that even some of the public processions and the sports with which the inhabitants of Chester have been from time immemorial entertained, may be continuations of Saxon usages. Chester had also in Saxon times a large *shire* attached to it, which in form has been aptly compared to an eagle's wing, the tip of it touching on Yorkshire. This was called Chester-shire (Cestrescyre), contracted into Cheshire. The bishop of Lichfield was also in remote times not unfrequently called bishop of Chester.

At the Conquest this shire was given by one sweeping grant (with the exception only of what belonged to the bishop) to Hugh of Avranche, commonly called Hugh Lupus, or Hugh Wolf, who had for his favourite device the Wolf's Head. Hugh was a near relation of the Conqueror, and possessed this portion of the conquered country with the Saxon title of Earl, but with some privileges which did not always accompany such concessions. Cheshire became what is called a County Palatine, having courts peculiar to itself and the custody of its own records. Hugh resided in the castle at Chester, and there he held his courts and parliaments, in which sat the superiors of the religious houses of the county, together with the eight great subinfeudatories, among whom he distributed the greater portion of his territory. The succeeding earls of his family, of whom there were six, maintained the same state. The series terminated in the reign of Henry III., and from that time the Earldom of Chester has been in the crown or in the hands of members of the royal house. Most of the large tenures created by the Conqueror reverted sooner or later to the crown by forfeiture or marriage.

The period from the Conquest to the reformation of religion, forms another great æra in the history of English cities. In that period Chester was often visited by the king, and was occasionally the scene of interesting public events. It has had a series of charters, by which valuable privileges were granted or confirmed, from the beginning to the close of that period, viz., from Hugh Lupus and some other of the succeeding earls of Chester, and when they were extinct, from the Kings Edward the First and Third, Richard the Second, and Henry the Seventh. As early as 1242 there is found a person with the title of mayor, who presided over a guild merchant or mercatorial. Chester was in those times a place of considerable trade. Beside the great monastery of Saint Werburgh, there was a religious community of women established within its walls: the black, the white, and the grey friars, had each an establishment in Chester: a college of the Holy Cross is mentioned, and hospitals of Saint Anne and of Saint John the Baptist, of which the latter escaped suppression at the Reformation, and continues to this day; besides numerous parish churches, all of which were founded before the close of the period of which we are speaking.

Chester had, during this period, among its inhabitants, some whose names are connected with the early literature of England; we have already mentioned three such persons, and it may be added, that Higden, the most celebrated of the three, whose æra was the reign of Edward III., is supposed to be the author of a set of mysteries, or religious dramas, which were exhibited by the several trades in Chester from time to time, and of which copies have descended to the present day.

Towards the close of the reign of King Henry VIII., two great changes took place at Chester. First, in the 34th of that reign, writs were first issued to it to send members to parliament; and second, it became the seat of one of the newly appointed bishops. The house of Saint Werburgh being dissolved, its church became the cathedral of the new see. A dean and six prebendaries were placed in it, Thomas Clark, the last abbot of Saint Werburgh, in Chester, being made the first dean. The revenue of the dissolved monastery furnished a provision for the prebendaries, dean, and bishop. The diocese assigned to him was the whole county of Chester, which had previously been under the superintendence of the bishop of Lichfield, and the county of Lancaster, with the archdeaconry of Richmond, part of the antient diocese of York. At the same period, 1544, a grammar school was founded, and Chester was appointed, about the same time, one of the sanctuary places.

From the period of the Reformation to the present time there are no very striking events in the history of Chester, nothing which in any eminent degree affected the condition or character of the place. It occasionally received royal visitants, and in the civil wars it had to endure a protracted siege. King Charles I. was for a time in the city, and from one of the towers, on the walls, is said to have personally witnessed the defeat of his army on Rowton Heath. The three earliest charters in the possession of the corporation were granted by Ranulph or Randle, earl of Chester, early in the thirteenth century. Charters were granted or renewed by several monarchs, and its corporation and parliamentary annals exhibit the usual amount of party struggles and disputed rights; so that the Reform Act, and the Municipal Corporation Reform Act, may be regarded as what more than any thing else in its more recent history will influence the future character and condition of the place. Previously to the passing of the Reform Act, the election of members of parliament was in the freemen, who were usually about 1200. The city was divided into twelve wards and nine parishes.

The modern history of the trade of Chester is rather the history of its decay, to which the prosperity of the port of Liverpool has in some degree contributed; but this decline is partly owing to the bad navigation of the Dee. A few gloves are manufactured here, and Chester has long had a reputation for the making of tobacco-pipes. Its fairs, of which there were two of very early date, and one by a charter of King Charles II., were long amongst the most celebrated of that species of mart, as long as the inland consumption was chiefly supplied in that way. King William established a mint at Chester, which had however no long continuance. A canal, which was cut in 1772, had no success till after many years the company united themselves to the proprietors of the Ellesmere canal. When the Act of Toleration gave liberty to the non-conforming Protestants to meet publicly for worship, they erected a spacious meeting-house in Chester, one of the earliest ministers in which was Matthew Henry, whose writings were long in great esteem in the non-conformist body. The modern Independents, the Baptists, and the Quakers, have each meeting-places in Chester; there are also a Roman Catholic and five Methodist chapels. The grammar-school of Chester, called the King's School, which is attached to the cathedral, is under the direction of the dean and chapter; there is also the marquis of Westminster's school, for 400 or 450 boys and girls, who are educated at the expense of the marquis; a diocesan school, and three infant schools. Chester has had many public benefactors, so that its charities are numerous. In 1700 a blue-coat school was founded, and in 1750 another for girls. The General Infirmary was opened in 1761. In 1763 an act of parliament was passed for the regulation of a house of industry; there is also a school of industry; and sunday-schools were established when first the idea was suggested.

Chester has always been the residence of many families of gentry. It has its theatre, its assembly, and its races. Several persons of literary eminence have resided here in recent times, as Dr. Haygarth and Mr. Falconer. In the seventeenth century Chester was the residence of a remarkable family named Holme. A taste for accumulating local and historical information appeared in four successive generations of this family, the individuals all bearing the name of Randal. The last Randal Holme being poor sold the whole collection to the earl of Oxford, who was then forming his great library. These manuscripts came with the rest of the Harleian collection to the British Museum, where they form 267 volumes, numbered in the catalogue 1920—2187; they abound in minute information, especially respecting Chester and the whole county.

The population of Chester, in 1774, was 14,713 persons; in the last census, 1831, it was 21,344. The number of houses inhabited was 4096; uninhabited, 388; building, 43. The number of families, 4628; of which 355 were chiefly employed in agriculture; 2665 in trade, manufactures, and handicraft; and 1608 not comprised in either of those classes: the number of marriages in 1830 was 396.

Chester is one of the very few places in England which have maintained in a tolerable state of completeness the walls which were erected for their defence in remote ages; at no place are they so entire as at Chester. But now, instead of contributing to the defence of the inhabitants, they afford only an agreeable promenade, with pleasant views, at various points, of the surrounding country; they are nearly two miles in circuit. The walls and the rows are two most striking objects in Chester to a stranger. The rows are a species of wide foot-path, raised above the level of the street, at the height of the first story of a house, and covered over head by the third story of the house; it is as if the room in a series of houses was thrown open, or rather taken away, which would otherwise be what is usually called the front room of the first floor. The two great intersecting streets are, for the most part, constructed on this plan: Pennant supposes that this mode of construction may have existed from the Roman times. The corporate officers of Chester, previously to the late Act, were a mayor, recorder, two sheriffs, twenty-four aldermen, and forty common-councilmen.

(King's *Vale Royal*; Lysons's *Magna Britannia*; *the Chester Guide*; *the Stranger in Chester*, *&c.*; *Municipal Corporations' Reports*.)

CHESTER-LE-STREET. [DURHAM.]

CHESTERFIELD, a parish, municipal borough, and market-town in the hundred of Scarsdale, Derbyshire, 132 miles N. by W. from London. The parish of Chesterfield, which contains several chapelries, hamlets, and townships, has an area of 13,160 acres, with, in 1831, a population of 10,688, which is an increase of 1498 on the census of 1821. This is attributed, principally, to an increase of collieries and iron works. The population of the borough of Chesterfield in 1801, was 4267; in 1811, 4476; in 1821, 5077; in 1831, 5775. Two rivulets, the Hyper and Rother, run past the town.

Chesterfield is conjectured, from its name, to have been a Roman station. At the Norman survey it was an insignificant place. The town received various privileges from King John, but was not incorporated till the reign of Elizabeth. Under the Municipal Corporations' Act, it is governed by four aldermen and twelve councillors, but is not divided into wards. The limits of the borough are co-extensive with the township, which is about four miles in circumference. The town is lighted under an act passed in 1825. In and near the town there are silk, lace, and pipe manufactories, potteries, and iron founderies.

Chesterfield Church, erected during the thirteenth century, is a beautiful and spacious edifice. The spire is remarkable from being crooked. This crookedness, which was supposed to be merely apparent, has been ascertained to be real, by actual measurement. The bulging out of a portion of the middle of the spire causes the ball on the summit to deviate from the perpendicular six feet towards the south, and four feet four inches towards the west. The spire is 230 feet high. Its crookedness may be the result of some accident (perhaps the effect of lightning) which is not recorded.

There were in 1835 twenty-six daily and Sunday schools in the town of Chesterfield. A grammar or free-school, founded in the reign of Elizabeth, and formerly well attended, has been closed since 1832. It was under the management of the corporation. There are various public and benevolent institutions, and a literary and philosophical society in the town.

The Chesterfield Canal, which commences in the tideway of the Trent, after a course of forty-six miles, terminates at Chesterfield. This canal was planned by Brindley. It has sixty-five locks, and is carried through two tunnels, one of which is 2850 yards long. The North Midland Railway, between Derby and Leeds, will be carried past Chesterfield. (Woodhead's *Account of the Borough of Chesterfield for* 1835.)

CHESTERFIELD, PHILIP DORMER STANHOPE, fourth earl of, was born in London on the 22nd of September, 1694. He was educated by a private tutor, and at the age of 18 sent to Trinity College, Cambridge, where he studied the Greek and Roman writers with unusual diligence. He tells us that he narrowly escaped becoming a pedant, a character for which he had the greatest contempt in after life; and that he drank and smoked at college notwithstanding his aversion to wine and tobacco, because he thought such practices were *genteel*, and made him look like a man. In 1714 he left the University to make the usual grand tour of Europe. He passed the summer at the Hague, where his fashionable associates not only laughed him out of his pedantry, but initiated him into a love of play which never forsook him. Many years after he tells his son in one of his letters that at the Hague he thought gambling an accomplishment, and as he aimed at fashionable perfection he adopted cards and dice as a necessary step towards it. From the gamblers of the Hague he went to the fashionable ladies and titled courtezans of Paris, who, as he was accustomed to boast, completed his education and gave him his 'final polish.' He was at Venice, when the accession of George I. in 1715, induced him to return home with great speed, in order to be in time for a court place. Through the interest of his family connexions, he was made a gentleman of the bed-chamber to the Prince of Wales, afterwards George II. In the first parliament of the new reign he was returned for St. Germains in Cornwall, and as he was determined to attract attention, from the moment of his election he studied nothing and thought of nothing, for a whole month, but his maiden speech. Though he afterwards became an accomplished orator, his first effort was rather a failure, and betrayed a violence of manner not at all consistent with his smooth silken code. The speech was otherwise unfortunate, for it attracted attention to the fact that he was not quite of age, and consequently liable not only to expulsion from the Commons' house, but also to a fine of 500*l*. An opponent mentioned this to him privately as a good mode of silencing his zeal: Chesterfield took the hint, and withdrew for some months to Paris, where, as it was always suspected, he was engaged in some secret court-intrigue. He returned in 1716, and resuming his seat, spoke in favour of the Septennial Act. In the inveterate quarrel which broke out between George I. and his heir, he adhered to the Prince of Wales, nor could his uncle, General (afterwards Earl of) Stanhope, who was then at the height of favour, with plenty of places at his disposal, ever induce him to change sides. Being much with the heir apparent, he undertook the difficult task of transforming a German prince into a British king, and of making a fashionable and a most refined man (as he understood it) of the rough and homely George.

His first division in parliament against the ministry was on a motion for the repeal of the Schism Bills, where he decidedly took the illiberal side of the question, 'supposing,' as he lived to confess with shame, 'that it was impossible for the honestest man in the world to be saved out of the pale of the church; not considering that matters of belief do not depend upon the will; that it is as natural and as allowable that another man should differ in opinion from me, as that I should differ from him; and that if we are both sincere, we are both blameless, and should consequently have mutual indulgence for each other.'

In 1726 he was removed by the death of his father to the House of Lords, where, according to his biographer, Dr. Maty, his manner of speaking was much more admired than it had been in the Commons. He was constitutionally weak, and devoid of strong passions, and as a speaker had little faculty of touching the higher feelings of others, but he was brilliant, witty, and perspicuous—a great master of irony, and was allowed by all his contemporaries to be a very effective debater. On the accession of George II., whom, as prince, he had steadily served for thirteen years, Chesterfield expected a rich harvest of honours and places; but having mistaken the relative amount of the influence exercised on his master's mind by the queen and the mistress, he paid his court to Mrs. Howard (afterwards Lady Suffolk), and neglected Queen Caroline, who eventually proving to be more powerful than the mistress, checked his aspiring hopes. He was not alone in this error:—Lord Bolingbroke, Lord Bathurst, Swift, Pope, and many others of less fame, shared in it, and in the consequent disappointment. Pope's villa at Twickenham was the place of rendezvous, where the royal mistress used to receive the incense of Chesterfield and the rest who had hoped to rise through her favour. In 1728, the year after the accession, Lord Chesterfield accepted the embassy to Holland, where he gained the friendship of Simon Van Slingeland, a distinguished statesman and then Grand Pensionary, and assiduously cultivated his talent for diplomacy. To Slingeland he afterwards acknowledged the greatest obligation, calling him his 'friend, master, and guide,' and adding, 'for I was then quite new in business, and he instructed me, he loved me, he trusted me.' Chesterfield had the merit of averting a war from Hanover, for which service George II. made him High Steward of the Household and Knight of the Garter. Under the plea of ill health he obtained his recall from Holland in 1732, and returning to court, where his office of Steward gave him constant access, he again indulged the hope of rising. A curious anecdote is told by Horace Walpole, to account for the renewed displeasure and animosity of the queen, and for Chesterfield's sudden secession from the court party. (Walpole's *Reminiscences*.) No sooner had his Lordship shown his decided opposition to Sir Robert Walpole, than he was deprived of the High-Stewardship, and so badly received at court, that he soon ceased visiting there altogether. At the end of Sir Robert's ministry in 1742 Chesterfield went into opposition against the members of the new cabinet, with whom, when out of place, he had been accustomed to vote in the minority. On the coalition of parties known by the name of the 'broad-bottomed treaty,' he took office and was admitted into the cabinet, sorely against the inclination of the king, who considered him as a personal enemy. Chesterfield, while in opposition, had still further offended the king by repeatedly denouncing the union of the electorate of Hanover with the kingdom of England, and by proposing that they should be separated from each other, and allotted to different branches of the reigning family. At the beginning of 1745, the year of the Pretender's last war in Scotland, and a time of intrigue and difficulties, he was again dispatched as ambassador to Holland. In the course of the same year he was named while in Holland, Lord Lieutenant of Ireland, and immediately repaired to his post, where he distinguished himself, in a season of very great turbulence, by his tolerant spirit, and conciliating popular manners. His short government in Ireland was perhaps the most valuable part of his public life. George II., whose prejudices were removed or weakened, recalled him from Dublin in April, 1746, and appointed him Principal Secretary of State. In consequence of being obstructed in some measures which he considered important, and of his now really declining health, he resigned his office in January, 1748, much, it is said, to the regret of the king. He was kept from the House of Lords by his giddiness and deafness, but in 1751 he delivered an elegant speech in favour of adopting the New Style. His declining years, though now and then brightened by flashes of wit and merriment, were clouded by sickness and despondency. He died on the 24th of March, 1773, in the 79th year of his age. His natural son, to whom his well-known Letters were addressed, died five years before him.

By his wife, Melusina Schulemberg, Countess of Walsingham, and niece to George the First's mistress, the Duchess of Kendal, he had no issue. After much opposition from George II., who pretended to found his objection on Chesterfield's incessant gambling, this German lady married his Lordship in 1733. Chesterfield always had a certain taste for literature and a partiality for the society of literary men; at different times of his life he associated with Addison, Pope, Swift, Gay, Arbuthnot, Voltaire, Montesquieu, and Algarotti. He patronized Hammond, a poet of third-rate merit, but an unfortunate amiable man, and procured him a seat in parliament. In his intercourse with Samuel Johnson he gave himself lordly airs, and the sturdy doctor, thinking himself slighted, avenged himself in the celebrated letter which was prefixed to the first edition of his Dictionary. His Letters to his Son, which appeared the year after his death, were never intended for publication. They have been much censured for the loose morality which they are supposed to inculcate; but still it must be admitted that they show a great knowledge of the world, and much practical good sense, expressed in an easy, agreeable, and correct style. His Miscellanies, consisting of papers printed in 'Fog's Journal,' and 'Common Sense,' of some of his speeches and other state papers, and a selection from his Letters to his Friends, in French and English, together with a Biographical Memoir, written by his friend and admirer, Doctor Maty, were published in 2 vols., 4to., in 1777. A third volume, of doubtful authenticity, was added in 1778. Chesterfield also wrote Nos. 100 and 101 in the 'World,' in praise of Johnson's Dictionary, and sundry copies of very light verses which appeared in Dodsley's collection. (Dr. Maty's *Life;* Lord Orford's *Works*, vol. i., p. 533, and vol. iv., p. 277.)

CHESTNUT. [ÆSCULUS; CASTANEA.]

CHEVAL DE FRIZE, a square or octagonal beam o. wood, from six to nine feet in length, and pierced by iron rods or wooden pickets six feet long, which are pointed at each end and shod with iron; the pickets are placed six inches asunder, and pass through two opposite faces of the beam in directions alternately at right angles to each other, the cheval resting on the ground at the lower extremities of the pickets. A series of these, disposed in lines and connected together by chains, is placed in the ditch, on the berme, at the entrances or behind the glacis of a field fort; or on the breach made in the rampart of a fortress, in order to impede the enemy at the time of making an attack.

Chevaux de frize, on account of their portability and the facility with which they can be put together or taken to pieces, were much esteemed formerly, and were employed in the open field as a protection against charges of cavalry; but they are now seldom used for this purpose, being easily deranged by the enemy's artillery.

When Badajos was besieged in 1812, chevaux de frize, formed by fixing sword blades in beams of wood, were planted by the defenders on the breaches in the Trinidad bastion and in the adjoining curtain, where they proved a fatal obstacle to the troops engaged in the memorable assault on that fortress.

CHEVIOT HILLS, THE, constitute the most eastern portion of the extensive mountain-range which begins on the west at Loch Ryan and traverses the whole breadth of South Scotland till it terminates on the boundary line between England and Scotland. Peel Fell, 55° 17′ N. lat., and 2° 35′ W. long., may be considered as the most western part of the Cheviot Hills. From this point the ridge runs N.E. for about 20 miles, and terminates in Cheviot Hill, the highest of its summits, which is 2658 feet above the sea. An elevated mountain tract, however, continues nearly due N. from this, separating the Breamish, which rises on the eastern declivities of the Cheviot Hill, from the Beaumont, which originates on its western side: this tract terminates at no great distance from the junction of these two rivers, which form the Till. To the E. of Cheviot Hill, but separated from the range by a valley, is Hedgehope 2325 feet above the sea. The highest parts of this range are covered with peat, and the lower acclivities with alluvial earth. The whole mountain-tract, especially towards the S., presents to the eye a great number of green hills, differing in form, and inclosing numerous deep, narrow, and sequestered valleys. The formation of the rocks is primitive, consisting of porphyry, especially east of Carter Fell. On Carter Fell, which is at a short distance from Peel Fell, limestone is quarried.

CHEVY CHACE, the name of an old English ballad, founded upon the history of a hunting encounter which took place in 1388 at Atterburn, upon the south of the Cheviot hills, between the martial families of Percy and Douglas. The older version of this ballad was first printed by Hearne, from a manuscript in the Ashmolean Museum at Oxford, and afterwards by Bishop Percy in the 'Reliques of ancient English Poetry.' It begins

'The Perse owt of Northombarlande.'

According to a communication made by the late Rev. J. J. Conybeare to the editors of the 'British Bibliographer,' there is now little doubt but that the author of this ballad was one Richard Sheale, who dwelt at Tamworth, whom Percy and Ritson both agreed to consider as the transcriber only of the Ashmolean copy. The style of this ballad is rugged and uncouth, and it is written in the very coarsest and broadest northern dialect. There seems the best reason for believing that its composition may be dated about or soon after 1540.

The more modern ballad of Chevy Chace, that of which Addison has criticised the beauties in the 'Spectator' (Nos. 70, 74), begins

'God prosper long our noble king.'

Bishop Percy ascribes this version to the time of Queen Elisabeth, and it was probably late in her reign when it was written, or Sir Philip Sydney would have had no occasion to lament that the ballad of Chevy Chace, in his time, was so 'evil-apparelled in the rugged garb of antiquity.'

Bishop Percy has printed both ballads in his 'Reliques,' edit. 1794, vol. i.: the old one at p. 1, the latter ballad, p. 270.

CHEYNE, GEORGE, was born in Scotland, in the year 1670. He was at first intended for the church, but after attending the lectures of Dr. Archibald Pitcairn, he determined to practise medicine. Having taken his doctor's degree, he came to London about 1700, and soon after published his 'Theory of Fevers,' in which he attempts to explain the doctrine of secretion on mechanical principles. His next work, 'On Fluxions,' was published in 1705, and procured his admission into the Royal Society. At a maturer age he called this a juvenile production, and acknowledged that it was justly censured by De Moivre, to whom and to Dr. Oliphant he makes an apology in the preface to his 'Essay on Health and Long Life,' for having treated their criticisms with rudeness. His 'Philosophical Principles of Natural Religion,' containing the elements of natural philosophy, and the evidence of natural religion to be deduced from them, was dedicated to the Earl of Roxburgh, for whose use it appears to have been written. An advertisement of the third edition makes mention of a second part, 'containing the nature of infinites, together with the philosophic principles of revealed religion;' but we do not know if this part was then first added.

Cheyne's natural disposition to corpulency was so increased by full living in London, that in a few years he became 'fat, short-breathed, lethargic, and listless.' His health gradually sank, and, after trying a variety of treatment with little benefit, he confined himself to milk, with 'seeds, bread, mealy roots, and fruit.' The experiment succeeded, and he was soon relieved of his most distressing symptoms. During his illness, being deserted by his 'bouncing, protesting, and undertaking' companions, who could not bear to see him in such misery and distress, he began to look to religion for consolation, and at last 'came to this firm and settled resolution in the main, viz., to neglect nothing to secure my eternal peace, more than if I had been certified I should die within the day; nor to mind any thing that my secular obligations and duties demanded of me, less than if I had been ensured to live fifty years more. This, though with infinite weakness and imperfection, has been much my settled intention in the main since.' (*The English Malady*, 2nd edit., p. 334.)

In 1722 he published an 'Essay on the true Nature and due Method of treating the Gout,' together with the virtues of the Bath waters, and the nature and cure of most chronic diseases. He had resided at Bath during the summers of several years, and attributed much of the benefit he had received to drinking the waters. In 1724 appeared his well-known 'Essay on Health and long Life,' in which he inculcates the necessity of a strict regimen, particularly in diet, both in preventing and curing diseases. It was dedicated to Sir Joseph Jekyll, Master of the Rolls, who had been under the author's care. In the preface he gives an account of his former works, which he censures where faulty, with great frankness, particularly when he had treated other writers with levity or disrespect. In 1733 he brought out his 'English Malady,' a treatise on the spleen and vapours, as well as hysteric and hypochondriacal diseases in general. This work, once very popular, contains a very minute account of the author's own case. It appears that on his recovery he gradually returned to a more generous diet. 'However, for near twenty years I continued sober, moderate, and plain in my diet, and in my greatest health drank not above a quart, or three pints at most, of wine any day (which I then absurdly thought necessary in my bulk and stowage, though certainly by far an over-dose), and that at dinner only, one half with my meat, with water, the other after, but none more that day, never tasting any supper, and at breakfast nothing but green tea, without any eatable; but by these means every dinner necessarily became a surfeit and a debauch; and in ten or twelve years I swelled to such an enormous size, that upon my last weighing I exceeded 32 stone. My breath became so short, that upon stepping into my chariot quickly, and with some effort, I was ready to faint away for want of breath, and my face turned black.' (*The English Malady*, 2nd edit., Lond., 1734, p. 342.)

He now returned to his low diet, and with the same success as before, though it required a longer time to re-establish his health. The proposal of a milk diet appears to have afforded much diversion to contemporary wits, some of whose gibes and sarcasms rather ruffled our author's complacency; but if it were worth while to refute epigrams, it would be easy to show that he was by no means a Pythagorean zealot: thus the very title of a chapter in his 'English Malady' is 'Of nervous cases, requiring a mixed or trimming regimen of diet, viz. of tender young animal food, and a little wine and water one day, and the other only milk, seeds, and vegetables.' Dr. Cheyne died at Bath, in 1742, at the age of 72.

CHIA'NA, VAL DI, a valley in Tuscany, in the province of Arezzo, running N. and S. 30 miles in length, from Arezzo to Chiusi, and between two chains of hills, of which the western divides it from the valley of the Ombrone, and the E. from the Thrasymene lake and the valley of the Tiber. The Chiana was once hardly anything but a vast marsh, and its air was pestilential, until the draining began under the Grand Duke Leopold I., which was finished under his son Ferdinand. By this operation above 36 square miles of ground are become now one of the most fertile districts of Tuscany. (Manetti, *Carte idrauliche sullo stato antico e moderno della Val di Chiana*; Fossombroni; Corsine, &c.) The waters of the N. and larger part of the Chiana now run N. into the Arno. In antient times they all flowed S. into the Tiber. [ARNO.]

CHIAROSCU'RO is a branch of painting, the object of which is to combine and arrange the light and dark parts of a picture to the best advantage. The term is derived from two Italian words, *chiaro*, light, and *oscuro*, dark, and includes the treatment of bright and dark colours or tints, as well as simple light and shade. It is by chiaroscuro that relief and depth, and what is termed the *effect* of a picture, are produced; by a judicious contrast of bright colours with dark, or a combination of the two, or by their gradual blending; by involving one part of the picture in shadow, while another part stands forth in full light; or by making the light gradually die away into the shadows. Leonardo da Vinci was the first who reduced the art of chiaroscuro to any thing like a system. It was afterwards practically improved by Correggio and by Titian, under whom it may be said to have attained perfection. It gives to Rubens all his richness and brilliancy, to Rembrandt his magical luminousness. It must however always remain, from its nature, difficult to teach or subject to rules. To acquire excellence in the use of chiaroscuro, the student should study the properties of light, and the mode in which it is diffused, collected, reflected, and separated into colours. He should refer to the works of the best masters, and observe the means which they have employed to imitate nature; and, above all, he should constantly watch and note down the effects of light and shade as exhibited in the objects around him under various modifications. The most powerful effects in painting will always be the nearest to nature; and the most pleasing will be those which are best selected out of the infinite variety which she presents for our choice.

CHIA'VARI, a province and town of the Sardinian States, in that part of the old Genoese territories called Riviera di Levante or E. coast. The province of Chiavari is bounded W. by that of Genoa, S. by the Mediterranean, N. by the province of Bobbio, E. and S.E. by that of La Spezia, and N.E. by the State of Parma. It is about 20 miles in length N.W. and S.E., and about 15 miles in its greatest breadth. The Apennines occupy the greater part of it; their summits divide it from the valley of the Trebbia, in the province of Bobbio, and from that of the Taro, in the State of Parma, the waters of which flow N. into the Po. The only rivers of the province are the mountain torrent of Rapallo, which runs into the Mediterranean, and the Vara, also a mountain stream, which flows E. into the Magra, which comes down from Pontremoli. The strip of land along the coast has a mild climate, in which the vine, olive, orange, and lemon thrive. The mountains abound with chestnut-trees. The inhabitants are chiefly employed on the sea.

Chiavari, a bustling place, with 9800 inhabitants, and a small harbour, is the residence of the intendente and of the courts of justice and commercial court: it has a college kept by the brothers Scholarum Piarum, besides the public elementary schools. Sestri di Levante has 7000 inhabitants; Rapallo is a pleasant town on the gulf of that name, with fine gardens and country-houses in the neighbourhood, and 9000 inhabitants; Santa Margherita, 6000; Lavagna, 5000; Varese, 5600; Borzonasca, 4700; and S. Stefano d'Aveto, 5700; the two last are inland among the Apennines. (*Calendario Sardo*, 1824.) The population of the whole province of Chiavari is about 91,000. (Serristori, *Saggio Statistico*.)

CHIAVENNA. [VALTELINA.]

CHICACOLE. [CIRCARS, NORTHERN.]

CHICHESTER, an antient walled city, the chief seat of a bishopric, to which it gives name, a parliamentary and municipal borough, and market-town, in the Rape of Chichester, western division of Sussex, 56 miles S.W. by S. from London, and about 6 miles from the sea-coast. It stands at the termination of a gentle descent from the South Down hills, on a slight rising ground sloping in all directions, in a low country, which is part of the plain that extends from the west side of Brighton to Portsmouth harbour, between the South Downs and the sea, and attains at Chichester its greatest width. The city within the walls, which are well preserved, is divided by two principal streets running north and south, and east and west, which intersect each other near the centre of the town; in this respect resembling Chester, and preserving the form of a Roman encampment. Beyond the walls the suburbs are prolonged in the direction of the principal streets. A small rivulet called [the Lavant, which is generally dry in summer, bounds the city on the east and south sides. The city and suburbs stand in eight parishes, besides an ecclesiastical precinct termed the Close, round the cathedral, and two extra-parochial pieces of land. The population of these in 1801 was 4744; in 1811, 6425; in 1821, 7362; in 1831, 8270. The number of inhabited houses in 1831 was 1514. These returns give 5·78 persons to a house in 1801, and 5·46 in 1831. There is no manufactory at present in Chichester. The cattle market, which is held every alternate Wednesday, is one of the largest in England held within the precincts of any town, and is always well supplied with cattle, horses, sheep, and pigs. There are several fairs in the town and the immediate vicinity at different stated times, but none are of great importance. Large quantities of corn are exported through the town for London and the west of England.

Chichester was undoubtedly a Roman station, probably Regnum. It is conjectured that Vespasian resided here, when in Britain, and that Claudius erected a temple in it, dedicated to Neptune and Minerva, of which an inscribed stone, dug up in 1731, is supposed to be a commemoration. The walls, which are nearly a mile and a half in circuit, were in all probability erected originally by the Romans. At the end of the principal streets there were formerly fortified gates, of which the eastern, the last standing (taken down in 1783), is said to have afforded decided proofs of Roman architecture. The present walls are supposed to have been re-constructed with the materials of the Roman walls, and a mound of earth (now planted in different parts with fine elm trees), which runs round the inside of the walls, is stated to be in the style in which the Romans constructed such works. But it is doubtful if there be any Roman remains now existing in the walls or buildings of the city.

The word Chichester is said to be a contraction of *Cissanceaster*, the city or castle of Cissa, an Anglo-Saxon chief, who, if credit can be given to the chronicles, repaired and partly rebuilt it, after it had been destroyed in a siege. At the Norman survey Chichester had only two hundred and thirty-eight houses, which were given to Roger de Montgomery, who was created the first earl of Chichester. This nobleman is believed to have been instrumental in procuring the removal of the seat of the bishopric of Sussex, or Selsea, from the peninsula of Selsea, where there was formerly a considerable town, to Chichester, which was one cause of the early prosperity of the place. The earliest charter extant is one by Stephen, confirming previously existing privileges and customs; which were further confirmed and extended by numerous charters from different kings. It is included in the list of towns of the Staple in the 27th Edward III., called Ordinatio Stapularum. Under the Municipal Corporations' Bill the city is divided into two wards, with six aldermen and eighteen councillors. It returned two members to Parliament from an early date. By the Reform Act the boundary of the parliamentary borough was enlarged considerably round the city.

A cathedral, built mostly of wood, was founded here in 1108. The present cathedral, which was erected during the 13th century, exhibits some specimens of Norman design, and also some examples of the first pointed style, when the Petworth or Sussex marble came into fashion. As a cathedral-church it is of an inferior class. but the spire, which is about a century later in date than the body of the building, is finely proportioned. The cathedral is built in the usual form of a cross; its extreme length from east to west is 407 feet; from north to south, 150 feet; the transept is 129 feet long, and 34 feet wide; the nave and aisles 97 feet wide; and the tower and spire 300 feet high. The north transept is now used as a parish church. In the interior there are nine monuments by Flaxman, one of them to the memory of William Collins, the poet, who was a native of Chichester. It also contains several antient monuments, which are curious, and some of more recent date that are not unworthy of notice. The best of the latter is in the form of a statue to the memory of Mr. Huskisson, who was for some time member for this city. It is the work of Carew, and was raised by subscription. At a short distance from the north-west angle of the cathedral is an insulated bell-tower, traditionally known as Ryman's tower, which is noted for its massive walls. The palace of the bishop of Chichester, whose diocese comprehends nearly the entire county of Sussex, is within the city. There is a neat antique chapel attached to the palace, which has been repaired by the late bishop, Dr. Maltby. Chichester stood a siege during the civil wars.

The average gross annual income of seven incumbents of the parishes of Chichester amounts to 664*l.*, but in six of the cases other preferments are held. (*Eccl. Ret.* 1835.) The various schools, daily and Sunday, amounted in 1835 to 29; and to these has recently been added an infant school. The schools of a distinct public character are—one Bell's school, one Lancaster ditto, both very flourishing, and educating a great number of boys; each of these has a girls' school belonging to it. The infant school is intended to accommodate about 250. A boarding-school was endowed in 1702 by Oliver Whitby, Esq., for 12 boys, but from an increase in its funds the number is now augmented to 28, who are boarded and educated. This school, which is under the direction of five trustees (who must be members of the church of England, and 'not parliament men'), is admirably managed; and the boys in the increased number are not only well taught, but are clothed. Such boys as behave properly receive a sum of money on leaving the school, to enable them to settle in business, or otherwise to promote their interests. The boys wear the antient blue dress of similar foundations. The revenue is about 1300*l.* per annum, and is yearly increasing. It is by the Foundation Charter restricted to members of the church of England. Another, termed a grammar-school, was founded in 1497 by bishop Story, the revenues of which are stated in the *Education Returns* to have been collusively administered. Scarcely any of the children of the citizens are educated at it, as it is exclusively a classical school. There is an antient foundation for the support of old and infirm poor persons, called St. Mary's Hospital. (*History of Chichester.*) Like so many of the antient charitable foundations, much too large a proportion of the funds of this hospital goes to the custos, or director, who is always one of the dignitaries of the cathedral, in the chapter of which lies the patronage of the charity.

The parochial churches in Chichester are remarkable for their smallness and the poverty of their appearance. During the present year, 1836, the largest parish (the Subdeanery) was divided, and a handsome Gothic church, capable of containing a thousand persons, erected without the walls. This church, which is surrounded with an extensive cemetery, is named St. Paul's.

The chief public buildings of Chichester are the guildhall, town or county-hall, council chamber, market-house, corn exchange, market cross, jail, theatre, infirmary, and the philosophical society's and mechanics' institutions. The town-hall is a rude inconvenient building, the remains of an antient monastery of Grey Friars. The council chamber, which is the official quarters of the corporation, is small, and far from ornamental; it is joined to an assembly room of large dimensions, in which most of the public meetings are held. The market-house is neat and commodious. The corn exchange is an elegant building, recently erected by subscription, and consisting of a splendid open show-room with stores for corn behind. The market cross, which stands at the intersection of the principal streets, is termed by Mr. Britton, 'the most enriched and beautiful example of this class of buildings in England.' Its form is an octagon, having a large central column, from which spring numerous bold ribs, beneath a vaulted roof; eight pier buttresses support the superincumbent panelled wall, parapet, pinnacles, and flying buttresses. There are three inscriptions on tablets, in niches, and clock-dials are inserted above them. The whole is surmounted by an open turret, of modern and inferior workmanship. The market-cross was erected by bishop Story towards the close of the fifteenth century; his arms are impaled with those of the reigning monarch on shields attached to the buttresses. The jail is small and inconvenient. The theatre is neat but small. The infirmary is a very elegant and beautiful building, situated on the northern slope outside the city, and surrounded with airing grounds for the patients. It was erected by subscription in 1826-7, and was opened for the reception of patients in October, 1827. It owes its establishment to the exertions of Dr. Forbes. It is one of the best planned and best regulated establishments in the kingdom, although of small extent; it contains about sixty beds, and is supported at an annual expense of about 1400*l.* The literary and philosophical society, which was established in 1831, and is very flourishing, has elegant and extensive premises in the South Street, with reading and exhibition rooms, and museum, which already contains a fine collection of birds and minerals, and many other articles of interest and value. Lectures are delivered regularly every winter before the members, now consisting of about 150, who pay an annual subscription of one guinea. The mechanics' institution was founded in 1829, and is also very flourishing; its present members amount to 450. In 1836 an elegant building for the purposes of the society was erected by subscription at the South Gate. Lectures before the members are regularly delivered during the winter, and are very well attended. This institution has no museum, but has an extensive well-selected library.

In 1817 an Act was passed for making a canal from Chichester harbour to the city, a distance of about a mile and a half, which forms a branch of the Portsmouth and London canal, by the way of Arundel. There is a quay on the harbour, to which vessels of 150 to 180 tons can come up at high tides. The canal has not been very profitable, as the dues are stated to equal the land carriage from the quay. The following statement shows the number of vessels with the tonnage:—

FOREIGN.

Years.	Inwards.		Outwards.	
1830	6	410	3	120
1831	7	426	3	188
1832	5	300	2	113

COASTWISE.

	Inwards.		Outwards.	
1830	283	23,914	256	10,342
1831	398	25,730	288	12,555
1832	385	27,408	251	9,461

The gross receipt of Customs' revenue collected at Chichester in 1833 was 1034*l.*; in 1834, 1529*l.*

Chichester has a clean, neat, and comfortable appearance; the city is well built, lighted, watered, and drained; the principal streets are spacious, and contain many large houses.

There are annual horse races in the neighbourhood, at Goodwood Park, the seat of the Duke of Richmond, which attract numerous visitors. (Britton's *Picturesque Antiquities; Geography of the Society for Diffusion of Useful Knowledge; Boundary and Municipal Corporations Reports;* Hay's *Hist. of Chichester; Communication from Chichester.*)

CHICK PEA. [CICER.]

CHICKASAWS, an Indian tribe in the United States of America, inhabiting the northern portion of the State of Mississippi, on both sides of the upper branches of the rivers Tombigbee and Yazoo. They were formerly more numerous, but they have been considerably reduced by war and the small-pox. At present their number does not appear to exceed 3000. They speak a language similar to that of their southern neighbours, the Choctaws, and have made some progress in civilization; they cultivate corn, cotton, potatoes, and beet-root; and have herds of cattle, sheep, and swine. They live in comfortable cabins, and have erected a school at their own expense. A few missionaries are active in imparting religious instruction to them.

CHICKWEED, a common annual, with soft light green opposite ovate leaves, a brittle stem, and minute white petals, almost split into two parts. It and groundsel are two plants which are to be found in flower on any day in the year; botanists name it *Stellaria media.*

CHICORY is a perennial plant bearing a composite flower, which gives the name to the sub-family or section of the *chicoraceæ*, which belongs to the family *Compositæ.* It has a fusiform root like a carrot, from the crown of which large and succulent leaves spread out, with deeply indented edges. The whole plant is bitter and aromatic; and the leaves as well as the root have been used in medicine, in the form of a decoction, as a tonic bitter and diuretic. It is frequently used as a salad, especially when blanched. For this purpose, the roots are taken up in the end of autumn; they are then placed in sand or light mould, in a cellar from which the light is excluded, the leaves having been cut off previously within half an inch of the crown. Fresh slender leaves soon grow out of the root, and, being deprived of light, they are much more delicate and tender than those which grow in the open ground. The bitterness also is thus lessened, and they form a very pleasant winter salad, which, from the long, slender, and matted state of the leaves, the French call *barbe de capuçin* (monk's beard). It is pleasanter to the taste than common endive, and stimulates the stomach by its bitter and aromatic quality.

The luxuriant growth of the leaves of the chicory, and their speedy reproduction after they have been cut, suggested the more extensive cultivation of this plant as food for cattle and sheep, who are fond of the leaves. Mr. Cretté de Panuel, who cultivated it near Paris in a rich soil, produced extraordinary crops. The first year he cut it only twice, but afterwards four and five times in a year: it produced more green food than any other plant cultivated for this purpose. Arthur Young was so struck with it that he strongly recommended it to the notice of British agriculturists; and in the queries sent to various parts of the country by the Board of Agriculture, one was, whether chicory was cultivated in the district as green food for cattle. But notwithstanding its abundant produce, it has not been found so much superior to other green food as to make its cultivation general. Some accurate experiments on a large scale were made in France at the national farm of Rambouillet, to ascertain the value of chicory compared with lucerne and other green food. The chicory was declared inferior, giving a disagreeable taste to milk and butter when cows are kept upon it. For sheep it is very good, and a small portion mixed with their other food may probably be a preservative against the rot.

Chicory is now chiefly cultivated in Belgium and Germany, for the purpose of preparing from the root a powder which can be substituted for coffee. This has become a very considerable article of commerce. It was very lately introduced into Britain, and the consumption of it, and consequent demand, increased so rapidly, that the government thought proper to put a check on its importation by a duty of 20*l.* per ton on the dried root.

To have the roots in perfection, the seed should be sown, or rather drilled, in April, like that of the carrot. If sown sooner, they are apt to run to seed. The land should be rich, deep, and light. The plants should be thinned out to six inches in the rows, and most carefully weeded. In September the leaves should be finally gathered and the roots taken up, which may be done with a common potato-fork. They are then cleaned by scraping and washing, split where they are thickest, and cut across in pieces about two or three inches long. These pieces are dried by means of a slow oven or a kiln. Some nicety is required in drying, to prevent the root from being scorched and to keep the proper flavour. In this state it is sold to the merchants, packed in bags. It is afterwards cut or chopped into small pieces, and roasted exactly as coffee, ground in a mill, and packed in papers in pounds and half pounds for retail sale. When coffee, as well as all colonial produce, became too dear for the labouring classes in France and Germany, chicory was almost universally used as the best substitute, and the taste is by many thought so grateful, that they prefer the coffee with which a fourth or a fifth part of chicory has been mixed. Chicory is said to exhaust the soil, and to require fresh ground to prevent its degenerating. Unless the soil is rich and light, the roots will not come to a good size in one season, and old roots become tough and stringy. It is only the young roots that are fit to be prepared for commerce. They lose a great portion of their weight in drying. The best preparation of the land for chicory is grass or clover. The manure should be laid on before it is ploughed up in autumn, which will accelerate the decomposition of the roots. The land should be ploughed very deep in spring, and laid light; the surface harrowed fine, and the chicory seed drilled in rows twelve inches apart, and rolled. Liquid manure spread over the ground will much accelerate the growth of the plants, which must be thinned out like turnips or carrots to six or eight inches from plant to plant.

CHIEMSEE. [Bavaria, p. 51.]

CHIHUAHUA. [Mexico.]

CHILBLAIN, a local but peculiar inflammation of the skin, commonly appearing under one of three forms. The mildest form is attended with redness, swelling, and a sense of heat and itching, often quite intolerable. In the second or severer form the colour of the swollen part is of a deeper red, sometimes of a dark blue colour, and at other times even of a purple hue. In the third or the severest form, small vesicles rise on the surface of the reddened and swollen skin, which are soon converted into sores, from which a thin irritating matter discharges, the irritating nature of which it is very difficult to alter, or to bring the sores into a state of healthy suppuration.

That the inflammation of which this troublesome complaint is the consequence is of a peculiar kind, not very well understood, surgeons conclude because they find that it is not relieved by the applications which are most beneficial in ordinary inflammation.

The exciting cause of chilblain is always cold, and more especially cold applied after the part had been previously much heated. Hence those persons are most subject to the complaint who have contracted the bad habit of going immediately to the fire when they come home in winter with their fingers and toes very cold. Hence also the chief seats of the disease are those parts of the body which are most exposed to sudden alternations of heat and cold, as the nose, ears, lips, toes, heels, and fingers. Young persons are more subject to it than adults, females than males, and it seems most frequently to attack persons of a fair skin.

The painful itching, which is perhaps the most troublesome part of this complaint, is best relieved by active and long-continued friction with camphorated spirits of wine, or with a mixture of two parts of camphorated spirits with one of Goulard's extract. Some surgeons speak highly of the efficacy of one part of the tincture of cantharides to six of the common soap liniment as a lotion. But 'one of the best modes of curing chilblains of the milder kind is to rub them with snow or ice-cold water, or to bathe them in ice-water several times a day, keeping them immersed each time until the pain and itching abate. After the parts have been rubbed or bathed in this way, they should be well dried with a towel and covered with flannel or leather socks.'

The stimulating applications, only in a more diluted form, appear also to be the best remedies when vesications arise. In this case the application of heat to the part affected should be most carefully avoided. When the vesicles terminate in sores, they require stimulating dressings.

But prevention is better than cure, and the most effectual mode of guarding against the annoyance of this irritating and often exceedingly protracted disease is to accustom the skin to moderate friction, to avoid clothing the parts too warmly, to avoid still more carefully sudden and great alternations of heat and cold; and accordingly to take particular care not to go immediately into a warm room or near a fire out of the cold air; and to wash the parts frequently with cold water. (Cooper's *Surgical Dictionary.*)

CHILE, one of the new republics on the continent of South America, lies along the shores of the Pacific between 25° and 42° S. lat.; but the archipelago of Chiloë, which also belongs to it, extends about two degrees farther south. The republic of Chile considers the whole coast to the Strait of Magalhaens, and likewise a portion of Patagonia, as belonging to its territories; but as no settlements have been formed in these countries, we shall limit our description to the tract, between 25° and 42° N. lat., which extends from the chain of the Andes, forming its eastern boundary (between 69° and 71° W. long.), to the shores of the Pacific Ocean (between 71°, 70° and 74° W. long.)

Chile is bounded on the east by the republic of La Plata, from which it is divided by the Andes. On the north it borders on the desert of Atacama, which belongs to Bolivia. On the west it is washed by the Pacific; and on the south it is separated from the island of Chiloë by the Strait of Chacao, and bounded by the Bay of Ancud.

Its extent from north to south is about 1175 miles; its breadth varies between 100 and 200 miles; and its mean may be taken at 150 miles. This would give it a surface of 176,250 square miles, which does not differ much from the calculation of Humboldt, who assigns to it an area of 14,240 Spanish leagues (20 = 1 degree), or 170,880 square miles. It is therefore about 60,000 square miles larger than the British islands.

The Andes, which from the Strait of Magalhaens as far north as the Bay of Ancud press close on the shores of the Pacific, appear to turn east at the northern extremity of that bay, but soon resume their northern direction, in which with some slight bends to the east and west they continue along the boundary line of Chile. So far as we yet know, they constitute up to 35° S. lat. one single range, about 100 miles or more in width. Between 35° and 34° S. lat. they divide into two ranges, which unite again north of 34°, and inclose the elevated longitudinal valley of Tunyan, the most southern of those valleys by which the Andes are distinguished from all other mountain ranges. About 33° 20′ the chain divides again, and incloses the longitudinal valley of Uspallata, which extends northward to 30° S. lat.: the elevation of this valley at the post-house of Uspallata was found by Miers to be 5970 feet above the sea. It belongs to the state of La Plata. No part of the Chilian Andes has been measured, except three mountain passes; but some of the numerous peaks in the chain have been estimated to rise to 15,000 and 16,000 feet. This estimate is founded on the fact that in these latitudes the snow-line is found at about 14,000 feet above the sea. The summits, which are covered with perpetual snow, are the Peak of Aconcagua (south of 32°), the Peak of Tupungato (south of 33°), the Volcano Penqueñes (near 34°), the Peak of Descabezado (north of 36°), and the Volcano of Antuco (north of 37°). The mean height of the whole range seems to be lower south of 35° than north of it, though the summits in the whole range seem to attain nearly the same elevation. This portion of the Andes contains many volcanoes. They are extremely numerous to the south of 35°, where nearly twenty are known to exist, and it is supposed that many are still unknown. Between 35° and 30° only a few occur, and at great distances from one another. Still farther north no volcano is known to exist in the Andes, between that of Coquimbo (south of 30°), and that of Atacama (south of 21°).

Several mountain-passes traverse this range. The most frequented is that of Aconcagua, which passes over the range between the peaks of Aconcagua and Tupungato, traverses the valley of Uspallata, and unites Santiago de Chile with Mendoza in La Plata. Its highest point, called La Cumbre, is, according to the calculation of Pentland, 12,454 feet above the sea. The pass of the Portillo traverses the Andes south of the peak of Tupungato, passing through the northern part of the valley of Tunyan. It seems to be the same road that Dr. Gillies measured, whose highest elevation he found to be 14,365 feet above the sea. South of the southern extremity of the valley of Tunyan, near the volcano Penqueñes, is another pass, which, according to Dr. Gillies, rises to 13,210 feet. The Pass del Planchon traverses the range between the volcano of Peteroa and the peak of Descabezado, and is less elevated than the others, since vegetation extends to its summit. The pass of Antuco, which crosses the range near the foot of the volcano of that name, probably does not rise to a great height. As it traverses the country of the independent Indians, who occupy the Pampas of La Plata, it is not much used. Besides these passes there are others over the Andes, but all of them are impracticable for mules in winter (from June to September).

The districts of Chile north of the Rio Chuapa (31° 30′ S. lat.) resemble the coast of Peru, and the whole of that country may be considered as the western declivity of the Andes. Near the high range the country is still between 6000 and 8000 feet above the sea, and it lowers gradually to the west.

till it terminates near the sea in an extensive plain, about twenty miles in breadth, and from sixty to eighty feet above the sea. The country between this plain and the chain of the Andes is very uneven, exhibiting numerous ridges of low hills, which in some parts, especially near the Andes, and near the plain along the shores, run parallel to the great chain and the Pacific; but in the intermediate country they continually change their direction. The surface of this country presents either bare rocks, or is covered with sand, and nearly without vegetation, except a few stunted shrubs, which generally occur in the narrow glens and ravines, with which it is sparingly intersected. A few rivers rising in the Andes run in deep beds through this country, but most of them have only water in the spring (September till December), when the snow is melting in the upper region of the Andes, and they are dry during eight or nine months of the year. Only three rivers, the Copiapò, Guasco, and Chuapa, have water all the year round. On their banks are the few cultivated spots, which are irrigated by water drawn from the rivers. But all the small level tracts along the watercourses are not fit for cultivation; the greater part of them are covered with incrustations of salt, which in some places are five or six inches thick, and occupy the whole surface, covering even the low grasses. The few spots which are cultivated produce only Indian corn, potatoes, a small quantity of wheat, and considerable quantities of fruits. Few countries of equal extent possess greater metallic wealth, especially gold, silver, and copper, but the extreme sterility of the country prevents the working of these mines, except when they are very rich. In climate these districts resemble Peru. It never rains, but sometimes a pretty strong dew falls in the morning, which refreshes the plants. This extreme dryness of the air is accompanied with a very moderate degree of heat, the thermometer in summer rarely attaining more than 70°; and in winter the temperature is sometimes so low, that the morning dew is changed into snow. This general description applies only to the country north of 30°, south of which line the cultivable spots are more extensive and more numerous, and the country is annually refreshed by a few showers of rain.

From the snow-capped peak of Aconcagua a mountain-ridge runs directly west, and terminates at a short distance from the sea. It is called Cuesta (ridge) de los Angeles, and attains a considerable height, which however greatly decreases as it proceeds westward. Another ridge, branching off from the Andes at the peak of Tupungato, runs first north-west, and is called Cuesta de la Dahesa: it then turns west, and may be said to terminate at the Campana de Quillota, a mountain which rises to about 2500 feet above the sea, from which it is about twelve miles distant. A much lower ridge extends farther west, terminating not far from the shore and the mouth of the Rio de Aconcagua. This westerly ridge, which is called Cuesta de Chacabuco, is traversed by the road which runs from the mountain-pass of the Cumbre, and attains in this place an elevation of 2896 feet above the sea. The country enclosed by the Cuesta de los Angeles, and those of La Dahesa and Chacabuco, is drained by the Rio de Aconcagua. This river rises on the north-west declivity of the peak of Tupungato, and runs more than one-third of its course in a narrow and elevated glen, nearly parallel to the chain of the Andes in a N.N.W. direction; it then gradually turns west, but the valley through which it flows is still narrow, till it has terminated another third of its course, when it enters the valley or plain of Aconcagua, a beautiful level tract, extending from E.S.E. to W.N.W. fifteen miles, with a breadth of thirteen where widest. This plain is about 2600 feet above the sea, but as the river has water enough to irrigate the whole, it is well cultivated, and perhaps the most populous portion of Chile. At its western extremity it lies nearly contiguous to the valley of Putuendo, which is smaller, but also fertile and well cultivated, and extends northward to the Cuesta de los Angeles. After the junction of the Rio de Aconcagua with the Rio Putuendo, the mountains again approach its bank, but soon retreat a little farther; and hence to the mouth of the river extends the valley of Quillota, which is not much inferior in fertility to the others, and is about three or four miles wide.

South of the Cuesta de Chacabuco the level country begins to occupy a much larger portion of the surface. The plain of Santiago, beginning at the foot of the range, extends south to the banks of the Rio Maypù. Towards the north it is from six to eight miles wide, but farther south it grows wider, and on the bank of the Maypù, from east to west, it is about twenty miles. Its soil is stony and dry, and it can not be cultivated where it is not irrigated. Cultivation accordingly exists only in the neighbourhood of the rivers, and of the canal, by which the water of the Maypù has been brought upon it. Miers thought that not one-tenth of the plain was under cultivation, but in this respect there has doubtless been some improvement of late years. The country between the plain and the Andes is filled by mountains of various heights, with steep declivities, and nearly without vegetation: the valleys intersecting them are narrow, and covered with an immense number of greater or smaller stones, which have fallen down from the adjacent mountains. The country between the plain of Santiago and the Pacific is traversed by some ranges of hills, which rise to no great height above the adjacent plains, and are southern offsets from the Cuesta of Chacabuco. The plains between them are pretty level, and of moderate extent: the soil is dry and stony, without water and trees.

The Rio Maypù has its sources in the Andes, between the Peak of Tupungato and that of Cauquenes, and one-third of its course lies between the high offsets of the Andes in narrow valleys. Towards the plain of Santiago its valley widens. When the river has entered the plain, the canal of Maypù conducts a portion of its waters to the centre of the plain, while the river, continuing its western course, traverses its southern portion. After its junction with the Rio de Colina, which traverses the plain of Santiago, but has water only in the rainy season, the Maypù enters the valley of Melipilli, from four to six miles wide, which contains large tracts of well-cultivated land. The whole course of the Maypù is about 160 miles.

The country south of the Rio Maypù has a different character. Towards the Andes it is covered with the high lateral branches of that range, which enclose narrow and elevated valleys. But about two-thirds of the country rise in gentle undulations, and contain comparatively few steep and high hills. Here also the rains are by no means abundant, nor do they last for any length of time: agriculture therefore cannot be carried on without irrigation, and the tracts of ground under cultivation are not extensive. To this want of moisture the naked face of the country must be attributed. No trees of large size are found in Chile north of the Rio Cachapoal, but their number increases farther south, till on the banks of the Rio Maule the forests of high timber trees become very extensive. The Rio Maule rises in the Andes at the foot of the Peak of Descabezado, near 36°, and runs first nearly due west. When it has arrived at the more level country it turns north-west, and flowing in a diagonal line, falls into the sea about 34° 40′. It is the most northern of the navigable rivers of Chile. At high tides vessels, not drawing more than six feet water, may enter its mouth, and proceed some small distance up it. Flat river-barges may ascend at any season for twenty miles and upwards. These favourable circumstances, united to the fertility of the country on its banks, and the extensive forests of timber trees, will probably soon render this river of considerable importance. The country between the Rio Maule and the Rio Biobio is still better adapted to agriculture; but since the expulsion of the Spaniards it has been nearly deserted, on account of the frequent incursions of the neighbouring Indian tribes. This tract contains much more level ground than any other portion of Chile. The Andes here terminate by a steep descent, and without offsets; and at their foot begins, in the northern districts, an undulating country, intersected with small plains. In the southern districts the level country begins immediately at the foot of the range, and extends to a considerable distance from it. The Travesia (heath) of Yumbel, a plain sixty miles long, and nearly as wide, between the towns of Yumbel and Tucapel, is covered with sand and small pieces of volcanic matter; it is without trees, water, and vegetation, except at a few spots. Poeppig thinks it probable that it was once covered with water, and formed a lake. A chain of low hills divides it on the south from the plain of the Isla de Laxa, which is nearly as large, and contains only a few low hills. This plain, which is covered with grass, is of great fertility. The country between this plain and the sea is covered with high but gently-sloping hills, which are partly clothed with wood, and partly bare and sterile. Along the rivers, especially the Biobio, the soil is very fertile.

The Rio Biobio rises in the Andes near 38°, and runs in a W.N.W. course to the Pacific, which it enters N. of 37° N. lat., after a course of about 150 miles. In its upper course it is deep and rapid. It becomes navigable for canoes and rafts at Nascimiento, 40 miles from its mouth, which Captain B. Hall found two miles wide, though too shallow for large vessels. This river may be considered as the southern boundary-line of Chile. To the S. of it, the republic possesses only the fortress of Valdivia, and a few smaller fortresses along the S. bank of the river. These fortifications, which were erected by the Spaniards to prevent the incursions of the Araucanians, having fallen into decay during the war of independence, the Indians were enabled to overrun the southern districts of Chile, and to lay them waste Of late years the republican government has rebuilt them, and is now enabled to defend these countries against the Indians.

Though the country S. of the Biobio is included in the territories of the republic, it is, with the exception of a few small tracts, entirely in possession of the independent tribes, called Araucanos. This country, so far as it is known, is nearly covered with high trees, which frequently form impenetrable forests. The surface seems to be nearly a level up to the foot of the Andes, with the exception of a range of hills running N. and S., and the soil very fertile, as may be inferred from the great number of warriors that the Indians can send into the field. The Rio Callacalla (also named Rio de Valdivia) is by far the deepest of the rivers of Chile: sixty-gun ships can enter its mouth without great danger; but it is not known how far it is navigable. Some of the smaller rivers are also said not to have a bar at their entrance, and to form pretty safe harbours for vessels of middling size.

The climate of the central portion of Chile, of which alone we have more particular information, may be compared in some degree with that of Italy. The greatest heat occurs in the months of January and February, at which time the thermometer on the coast frequently rises to 85° during the day, and 70° to 75° during the night. The hottest part of the day is before ten o'clock in the morning, about which time wind rises in the S., which often blows with great violence. In the interior, even in the elevated valley of Aconcagua, the thermometer frequently rises to 90° and 95° in the shade; and as the southern wind is not strong here, the days are sultry, but at sun-set a delightful breeze sets in, which cools the air. The months of March and April are much more temperate, especially in the interior, and at the end of the latter months the rains generally set in. Rains fall only between May and August, and then the Andes are covered with snow, which generally lies for four or five months on the higher parts of the range. Snow and also some ice occur in the elevated valleys, but it soon melts, and the atmosphere is only chilly while the rain is falling. Snow never occurs along the sea. The number of rainy days in the northern districts is commonly fourteen, and seldom more than twenty throughout the year. This rain, which is very heavy, seldom falls for more than three days continuously. In the southern districts, where the number of rainy days is much greater, being on an average forty, the rain sometimes continues ten days without intermission. After the rainy season, in September the spring begins, which is frequently more chilly than the winter itself, and ice is sometimes observed even on the coast. Whenever an easterly wind brings down the cold air from the snow-covered Andes, the thermometer sinks in a short time 15° or 18°, but soon rises again. Summer begins towards the commencement of November, and then the sky, which, during the spring, is covered with clouds, is entirely free from them. The heat gradually increases, and in the northern districts vegetation begins to die away in December, but in the southern districts the country is always clothed with verdure, as the plants are occasionally refreshed by rain, and the dews are frequent and heavy. The mean temperature at the mouth of the Rio Aconcagua in July and August is 70°, and at Talcahuana, near Concepcion, one or two degrees less.

Chile is subject to strong periodical gales. In the beginning of the rainy season (May and June) the north and north-western winds prevail, and frequently blow with great violence. As all the harbours of this coast are open to that quarter, vessels abandon them, and weather the storm in the open sea. During eight or nine months the wind blows from the S., and frequently with great force, especially in autumn (from February to April). At the same time a current runs along the coast to the N., both which circumstances favour navigation northward, but the return to the S is rendered very tedious and difficult. Easterly winds are rare, except in September, when, as already observed, they suddenly lower the thermometer, and in February and March. In the latter season they blow only in the valleys of the Andes, and raise the thermometer from 77° to 80° even in valleys which are upwards of 5000 feet above the sea. They blow with such a force, that they throw down the strongest trees.

Probably no country is more subject to earthquakes than Chile; they occur, however, much more frequently along the coast than in the interior. In the northern districts slight shocks are felt almost every day, and occasionally several times in a day. Sometimes they destroy the towns and lay waste a great extent of country. In 1819 the town of Copiapò was levelled to the ground, and in 1822 the damage done in Valparaiso and the country about it was not much less. In the last earthquake the rocks inclosing the harbour of Quintero, which is some miles N. of the mouth of the Rio Aconcagua, were raised four or five feet above their former level.

The climate of Chile varies much in the different districts; but it is every where so healthy, that it is difficult to determine what kind of diseases are prevalent.

Intertropical plants do not succeed; for though the heat in the northern district is great, the extreme dryness of the air is unfavourable to the growth of plants which require a long time for coming to maturity. The sugar-cane was tried some years ago, but it has been abandoned. Agriculture is limited to the productions of Europe. Indian corn is grown every where, but not to a great amount. Wheat is the staple; it is raised all over the country, and gives in many places very abundant crops, especially S. of the Rio Maule, whence considerable quantities of flour are exported to the harbours along the western coast of S. America, where it enters into competition with the flour brought from the United States. Large quantities are from time to time shipped to Cook's Land or New South Wales. Barley is grown in the southern provinces to some extent, but very little N. of the Rio Maule; oats only on a few estates, and rye is not known. Leguminous vegetables are grown abundantly, especially different kinds of beans, and supply an article of exportation. Hemp is raised in the country N. of the Rio Maypù, and grows to an extraordinary height. Since it has been ascertained that the hemp of Chile is superior even to the Russian, the state favours this branch of agriculture by granting to its cultivators many advantages. Hemp is grown in no other country on the W. coast of S. America.

Vegetables are not much cultivated, except in the countries about the capital and the most frequented parts. Potatoes however are grown in great abundance in the northern districts. Capsicum is raised in the valley of Aconcagua, and forms a considerable article in the internal commerce of the country. The quinoa (Chenopodium quinoa) is peculiar to Chile, which, in the southern provinces, is raised in abundance, and somewhat resembles millet; a pleasant beverage is made of it. Melons and water-melons, as well as pumpkins, succeed very well in the northern provinces, where they are raised in great quantities, and attain a surprising size.

Figs, grapes, pomegranates, oranges, and peaches succeed best in the most northern districts, whence they are exported to the other parts of the state. Wine is made at different places, but not yet with any great success. The best is made near Concepcion. The olive-tree succeeds as well as in Spain, and its cultivation is rapidly increasing, but the oil is bad for want of a proper method of preparing it. Extensive forests of wild apple and pear trees occur along the foot of the Andes in the southern provinces. The fruits are hardly eatable, but cider is made of them. The forests, which cover so considerable a portion of the southern provinces, contain many fine timber-trees, which form one of the more important articles of export. In the Andes S. of the volcano of Antuco, many valleys are covered with forests of the Araucaria, whose fruits contain a great number of nuts twice as large as an almond, which are very palatable, and constitute the principal food of the Indian tribe of the Pehuenches. (Poeppig.)

Cattle are very abundant north of the Rio Maule, the declivities of the mountains and high hills affording copious pasture for four or five months, and some low tracts which are sown with lucerne, for the remainder of the year. Single proprietors sometimes possess from 10,000 to 20,000 head of cattle. Live stock, jerked beef, tallow, and hides, are large articles of export. Cheese is made on the banks of the Rio Maule and sent to Peru; and butter in the neighbourhood of the larger towns. Horses have greatly decreased in number during the last twenty years. They are of a middling size and strong; of late years horses and mules have been exported to Cook's Land and the Cape of Good Hope. Sheep are not numerous, and their wool is bad. Goats are kept by the lower classes, but are not numerous. Swine are found in abundance in the archipelago of Chiloë, whence hams are exported; on the continent they are less numerous. Pork is salted in the harbours as provisions for the vessels. The island of Mocha, between Concepcion and Valdivia, is overrun with wild horses and pigs, both of which are used as fresh stock by the whaling and sealing ships in the Pacific.

Gold dust is found in the sand of nearly all the rivers which come down from the Andes, as in the Rio de Aconcagua, Rio Maule, and Biobio. Some twenty years ago many of the inhabitants on the banks of these streams were employed in washing the gold sand, but it is now only done in a few places. Some gold mines occur in the northern districts, where they are worked, but the produce is inconsiderable. Others are said to exist in the southern provinces, but none are worked. Silver is still more abundant, but the average is only from 9 to 10 marcs (one marc = 8 ounces) in the cargo, or 5000 lbs. of ore. In 1832 however very rich silver mines were discovered about sixty miles south of the town of Copiapò, where the ore was found so rich as frequently to contain 60 or 70 per cent. of pure metal. Their working has commenced with great activity, and all the other mines are nearly abandoned. Poeppig thinks that the produce of all the silver mines, even including the rich one discovered in that year, did not exceed 120,000 or 130,000 marcs. The copper mines are very numerous in the northern districts, especially about Illapel, Coquimbo, Copiapò, and Suasco; copper is also found farther south in the Andes, but is not worked. The copper of Copiapò is most valued. Miers estimated the quantity of copper exported in 1824 at 40,000 cwt.; in 1829 it rose to 60,000; the mean may be 50,000. A small portion comes to Europe, but by far the larger part goes to India and the United States. Ores of lead, tin, and iron, are said to exist, but they are not worked.

The coal formation extends under a considerable part of the southern provinces. The coal is at present bad, but it is hoped that it will improve in quality as the mines are sunk deeper. Salt does not exist in sufficient quantity. A good deal is collected in the lakes of Bucalemu, south of the mouth of the Rio Maypù, in which the salt water of the sea is subjected to evaporation. A great quantity of salt is imported from Peru and Patagonia. The latter is collected by the Indians, partly from lakes, and partly from the sides of mountains on the eastern sides of the Andes between 36° and 40° south latitude.

The population of Chile, north of the Rio Biobio, is entirely composed of descendants of Europeans. If there has been any mixture with the copper-coloured race, it must have been very small. There are no Indians north of the Biobio, except in the valleys of the Andes south of 34° S. lat. Negroes are few in number. The population is differently stated by travellers. Miers thought that it did not exceed 560,000, but the partial census of some provinces shows that he has much underrated it. Many who have seen the country are of opinion that 1,200,000 can hardly be too much. The most recent estimates carry it even to 1,400,000. The Indians who inhabit the country south of the Biobio are known by the name of Araucanians, and have obtained some celebrity by the high degree of civilization attributed to them by Molina [ARAUCANIANS], of which, however, modern travellers have been unable to find any traces. They appear to consist of several tribes, who speak different dialects of the same language, and are divided by the Chilenos into *Indios costinos*, or Indians inhabiting the coast, and into *Moluchos*, who inhabit the extensive wooded plains stretching along the foot of the Andes. It is the latter Indians who have resisted all attempts to conquer them, and have at last destroyed nearly all the settlements established south of the Biobio. These nations derive their principal subsistence from agriculture, cultivating Indian corn, potatoes, beans, and some other articles. In the valleys of the Andes between 34° and 37° S. lat. are the Pehuenches, who seem rather to be addicted to a wandering life. All these tribes still enjoy complete independence, and frequently ravage the southern districts between the Biobio and Maule in their incursions.

The country north of the Biobio is politically divided into six provinces, to which are added the province of Valdivia, comprehending the European settlements south of that river, and the province of Chiloë, which consists of the archipelago of that name.

I. The province of Coquimbo comprehends the most northern sterile portion of the republic; and has the Rio Chuapa for its boundary on the south. It exports gold, silver, and copper, and dried fruits. Its mines, which are the richest in Chile, are worked chiefly in the neighbourhood of the small towns of Coquimbo, Copiapò, Huasco, and Illapel. The capital is Ciudad de Serena, a small town with about 4000 inhabitants, situated somewhat more than six miles from the bay of Coquimbo.

II. The province of Aconcagua contains the valley of the Rio Aconcagua, and the countries north of it to the Rio Chuapa. It exports cattle and wheat, and has some rich mines of gold and copper. The capital, S. Felipe, or Villa Vieja de Aconcagua, contains above 10,000 souls. In the valley there are also Quillota, with 8000 inhabitants, and S. Rosa, or Villa Nueva de Aconcagua, of nearly equal size. Near Petorca there are rich mines of silver.

III. The province of Santiago comprehends the plains along the foot of the Andes on both sides of the Rio Maypù, and the hilly and in some places mountainous country between the plains and the Pacific. It contains few mines, and their produce is small. Its wealth consists in wheat and cattle. It contains the capital of the republic, Santiago, and the most frequented harbour, Valparaiso. Rancagua, towards its southern boundary, is a place of some importance.

IV. The province of Colchagua extends between the rivers Cachapoal and Maule, and comprehends a country partly level and partly hilly. It is of great fertility, and produces corn in abundance; cattle are also very numerous. It does not appear that there are any precious metals. In this province the immense forests begin which cover so considerable a portion of the south; farther north there are no forests. The capital, San Fernando, apparently one of the most considerable towns of the republic, is situated in a very fertile country. Talca is also a place of some note.

V. The province of Maule extends from the Rio Maule to the Rio Itata, and to its upper branch the Rio Ruble. It produces corn, wine, and tobacco, and is partly covered with lofty forest trees. It is probably the most fertile part of Chile, and consists mostly of an undulating country and some small plains. Copper abounds in some places; but cattle constitutes the principal wealth of the inhabitants. The chief town is Villa de Cauquenes, a small place situated in a well-cultivated plain.

VI. The province of Concepcion lies between the rivers Itata and Biobio, and comprehends the sandy plain of Yambel and the fertile plain of Isla de Laxa, with the hilly country extending between the plains and the sea. It is less fertile than Maule, a great part of its surface being occupied by the Travesia de Yambel and the sandy hills between it and the sea; but the remainder is very fertile, especially the plain of Laxa. Corn and timber are the principal exports. The capital is Concepcion. Chillan, in the interior, was formerly a place of some importance, but has been much reduced of late years by repeated invasions of the Indians.

VII. The province of Valdivia comprehends the countries between the Rio Biobio and the Bay of Ancud; but nearly all this tract is occupied by independent Indian tribes. Except the towns of Valdivia and Osorno, the European settlements are limited to a small number of fortifications along the banks of the Biobio, among which Nascimiento is the most important. Timber and a little corn are exported. The capital is Valdivia. Osorno, a small town, lies in 40° 20′ S. lat.

VIII. The province of Chiloë. [CHILOE.]

Chile is probably the only American state formerly subject to Spain whose commerce has increased since the separation from the mother country. The importations in 1832 amounted, according to a rough estimate of the merchants of Valparaiso, to about 1,000,000*l.*, and the exportation, including the transit commerce, did not fall much short of 1,500,000*l.* In Poeppig's 'Travels' the following table is given:

Countries and Harbours.	Articles of Import.	Articles of Export.
Bolivia: Cobija.	Bullion.	European and Indian goods; fruits.
Peru: Arica, Islai, Pisco, Lima, Lambayeque, and Paita.	Tobacco, sugar, cotton, rice, bullion, salt, spirits.	European and Indian goods; wheat, flour, wine, raisins; tallow, jerked beef, almonds, walnuts, timber.
Ecuador: Guayaquil.	Hats, sole-leather, cacao, bullion.	The same.
Central America: Realejo, S. Salvador, Guatemala.	Indigo, cigar-matches, dyeing wood, cochineal, saffron, balsams, hides, sugar, coffee, pearls.	European and Indian goods; wine, spirits, flour, fruits.
Mexico: Acapulco, S. Blas, Guaymas.	Bullion; sometimes sugar.	The same.
Manila.	Sugar, hats of palm-leaves, indigo.	Bullion.
China: Canton.	Silk goods; nankeens; tea, sugar, and some small articles.	Copper and bullion.
East Indies: Calcutta.	Sugar, coarse cotton goods.	Copper.
La Plata: Buenos Ayres.	European goods; produce of Brazil, sugar, maté.	Wheat, barley, beans, &c.
Brazil: Santos, Rio Janeiro.	Coarse cotton linen, called *tocuyos*.	Wheat, fruits, bullion.
United States: Baltimore, New York, Salem, Boston.	Tobacco, spermaceti candles, oil; European and Indian goods; sugar from Havanna and Brazil, &c.	Hides, copper, sealskins, bullion.
Spain: Cadiz and Gibraltar (by neutral vessels).	Wine, oil, quicksilver, paper, and some silk goods.	No direct exportation.
France: Bourdeaux, Hâvre—rarely Marseilles or Nantes.	Wine, brandy, silk goods; linens, cloth, hardwares; paper, perfumes; books; calf-leather, goat-leather.	Bullion, hides, and sometimes copper.
England: Liverpool and London.	Cotton and woollen goods; iron, hardwares, and iron utensils; crockery, &c.	Bullion, hides, and copper.
Germany: Hambro', Bremen.	Linens, cloth, glass; iron utensils; silk and cotton goods, spirits.	Bullion.
Belgium: Antwerp.	Cloth, and English, German, and French manufactured goods.	Bullion, hides.

Somewhat more than one third of the whole commerce is said to be in the hands of the English, about one-third belongs to the North Americans and French, and the remainder to the other European and American nations. [VALPARAISO.]

The revenues of the republic, from 1825 to 1830, amounted to 1,736,800 Spanish dollars: in 1831 only to 1,509,000, and in 1832 to 1,634,633. In 1832 they were estimated at 1,685,000; but up to the year 1832 the expenses exceeded the revenue, and the interest on the English loan of 1,000,000*l.* has not been paid. The army consisted in 1832 of 3200 men, besides the militia, which was estimated at 20,000. The navy, which formerly consisted of 12 vessels, was reduced in 1832 to two small vessels.

When Francisco Pizarro had overthrown the empire of the Incas in Peru, he sent Almagro to subjugate Chile. With great loss of men, Almagro, passing over the Andes and through the desert of Atacama, entered the northern provinces without resistance, these districts having previously been dependent on the Peruvian empire. But farther south he met the more warlike tribes, and made no great progress. His successor, Valdivia, advanced to the Biobio, and founded the town of Santiago in 1541. For more than 200 years the Spaniards tried to establish their authority in the south, but without permanent success; and in 1771 they were obliged to abandon that country, with the exception of Valdivia, Osorno, and a few small fortresses on the banks of the Biobio.

The first disturbances tending to a separation from the Spanish dominion occurred in 1810, and went on increasing till the Chilenos were defeated in 1814 at Rancagua, by the Spanish general Osorio. In 1817 San Martin entered Chile with an army from La Plata, and liberated the country by the battles of Chacabuco (12th February, 1817) and Maypù (5th April, 1818). The new government has a republican form; the provinces, however, do not constitute separate states, but have a central legislature and executive. The executive power is in the hands of a supreme director. The congress is composed of a senate, consisting of twenty members at the utmost, and of a house of representatives, to which a deputy is sent for every 15,000 souls. Since the establishment of the constitution, the conflict of the political parties has been nearly continuous, and the country has not yet derived from this change those advantages which were anticipated. (Molina; Miers; Meyen; *Reise um die erde in* 1830—32; Poeppig, *Reise in Chile, Peru, und auf dem Amazonenstrome in* 1827—32.)

CHI'LIAD (from χιλιάς) is (or rather was) used to mean a thousand consecutive numbers. Thus from 1 to 1000 forms the first chiliad, from 1001 to 2000 the second, and so on.

CHILINA, a genus of testaceous mollusks, separated by Mr. Gray from *Auricula*, and including *Auricula Dombeiana* of Lamarck, and *Auricula fluviatilis* of Lesson. Locality, South America, in fresh-water streams, with most of the habits of the *Limneæ*.

CHILLIES. [CAPSICUM.]

CHILLINGWORTH, WILLIAM, was the son of William Chillingworth, mayor of Oxford, where he was born in October, 1602. In 1618 he was a scholar, and in 1628 a fellow, of Trinity College in that University. Some curious memoirs of him are preserved by Anth. Wood (*Athen. Oxon.* c. 20), who says 'he would often walk in the college grove, and dispute with any scholar he met, purposely to facilitate and make the way of *wrangling* common with him, which was a fashion used in those days, especially among the disputing theologists, or those who set themselves apart purposely for divinity.' The comparative merits of the English and Romish churches were at that time a subject of zealous and incessant disputation among the university students; and several learned Jesuits succeeded in making distinguished proselytes among the Protestant clergy and nobility. Chillingworth, being an able disputant, was singled out by the famous Jesuit Fisher, alias Johannes Perseus (*Biblioth. Soc. Jesu*), by whom he was convinced of the necessity for an infallible living 'Rule of Faith.' On this he at once adopted the Catholic system, wrote out his reasons for abjuring Protestantism, and joined the Jesuits in their college at Douay.

After the lapse of a few months, the arguments addressed to him by his godfather, Dr. Laud, then bishop of London, induced him to abandon Catholicism, and he returned to Oxford in 1631, where he passed about four years in reconsidering the Protestant tenets. The great work of Daillè on the Fathers, which then first appeared, is said to have finally determined him.

In 1635 he published his 'Religion of Protestants, a safe way to Salvation.' It excited great attention, and passed through two editions in less than five months. For an account of the circumstances which occasioned this work, and for a list of the publications connected with the controversy, see Kippis's *Biog. Brit.*, vol. iii., p. 511. The principle of Chillingworth is, that the volume of Divine Scriptures, ascertained to be such by the ordinary rules of historical and critical investigation, is to be considered the sole authority of Christians, to the utter exclusion of ecclesiastical tradition. His boldness in asserting the principle of private judgment was opposed as much by the Puritans as by the Catholics; and while the Jesuit Knott, alias Matthias Wilson (*Biblioth. Patrum Soc. Jesu*, p. 185), contended that he 'destroyed the nature of faith by resolving it into reason,' Dr. Cheynell 'prayed that God would give him new light to deny his carnal reason, and submit to faith.' These were two of the most determined of Chillingworth's antagonists. Cheynell was one of the assembly of divines who, in 1646, was sent to convert the University of Oxford. (See *Midsummer Moon, or Lunacy Rampant, being a Character of Master Cheynell*, 1648.) Chillingworth in the mean time, unable to reason his conscience into an approval of the 39 Articles, refused to accept any preferment in the church. His long letter on the subject to Dr. Sheldon (afterwards archbishop of Canterbury), a most interesting document, is given in his Life, by Des Maizeaux, p. 86, and in Kippis's *Biog. Brit.* Nothing can be stronger than the expressions of refusal to subscribe with mental reservation. 'If I subscribe,' says Chillingworth, 'I subscribe my own damnation—if I will not juggle with my conscience and play with God Almighty I must forbear—to say the 4th Commandment appertains to Christians is false—the damning sentences in Athanasius's creed are most false, and in a high degree presumptuous—I am firmly and immovably resolved that if I can have no preferment without subscription, I neither can nor will have any.' However, in a very short time he was completely persuaded by the arguments of Drs. Sheldon and Laud, that peace and union are the real object of subscription, not belief or assent —a doctrine held by Archbishop Sancroft and many other eminent divines. Accordingly he accepted the chancellorship of Salisbury with the prebend of Brixworth, Northamptonshire, annexed; and in the subscription-book of Salisbury cathedral are recorded the words, 'Ego Gulielmus

Chillingworth, omnibus hisce articulis, et singulis in iisdem contentis volens, et ex animo, subscribo; et consensum meum iisdem præbeo, Jul. 20th, 1638.' Chillingworth, in 1640, was deputed by the chapter of Salisbury as their proctor to the Convocation in London. He was attached very zealously to the royal party, and wrote a treatise (unpublished) on 'The Unlawfulness of resisting the lawful Prince, although most impious, tyrannical, and idolatrous.' Being present in the army of Charles I. at the siege of Gloucester, August, 1643, he acted as engineer, and devised the construction of engines, in imitation of the Roman *testudines cum pluteis*, to assault the rebels and take the city by storm. Having accompanied the king's forces under Lord Hopton to Arundel castle, he was there with his comrades taken prisoner by the parliament army under Sir William Waller; and falling ill he was thence conveyed to the Bishop's palace at Chichester, where he died and was buried in Jan. 1644. In his epitaph (*Gent. Mag.*, vol. lxiv., p. 697), on the mural monument in that cathedral, he is styled 'Propugnator invictissimus Ecclesiæ Anglicanæ.' A singular scene occurred at his funeral. Dr. Cheynell, then rector of Petworth, appeared at the grave, with the work of Chillingworth (*Relig. of Protest.*) in his hand, and after an admonitory oration on the dangerous tendency of its rationalism, he flung it into the grave, exclaiming, 'Get thee gone, thou cursed book, which hast seduced so many precious souls—get thee gone, thou corrupt rotten book, earth to earth, dust to dust, go rot with thy author!' He afterwards published 'Chillingworthi Novissima, or the Sicknesse, Heresy, Death and Burial of Wm. C., with a prophane catechism collected out of his works, by F. Cheynell, Fell. Mert. Coll. Ox.,' 1644 and 1725. In this singular production the object of the author's enmity is jeered at as 'this man of reason whose head was as full of scruples as it was of engines.' But the character and abilities of Chillingworth have been greatly and justly extolled by many of our most distinguished writers. 'The incomparable Chillingworth,' says Dr. Tillotson, 'is the glory of his age and nation.' 'If you would have your son to reason well,' says Locke (*on Educat.*), 'let him read Chillingworth;' again (*on Study*), 'For attaining right reasoning I propose the constant reading of Chillingworth: for this purpose he deserves to be read over and over again.' Anth. Wood says that, 'having spent all his youth in disputation, he was a most subtle and quick disputant, and would often put the king's professor to a push.' Hobbes observes that 'he was like a lusty fighting fellow driving his enemies before him, and often giving his own party smart back blows.' 'Those,' says Mosheim, 'who desire to know the doctrines of the Church of England, must read especially Chillingworth's admirable book, The Religion of Protestants.' Gibbon observes that Chillingworth most ably maintains the principle that the protestant's sole judge is the Bible, and its sole interpreter, private judgment. Dr. Reid considers him 'the best reasoner and most acute logician of his age;' but Anth. Wood's opinion is not outdone by any, for he declares that 'Chillingworth had such extraordinary clear reason that if the great Turk or the Devil could be converted, *he* was able to do it.' 'His great excellency consisted,' says Dr. Barlow, 'in his acquired logic, the syllogisms of Aristotle and Crakenthorp having been a principal part of his studies.' The result of this proficiency in 'wrangling' is stated by his intimate friend Lord Clarendon, who says (*Hist. Rebell.*) that 'Chillingworth had contracted such an irresolution and habit of doubting, that at last he was confident of nothing.' This fact is adduced by Dugald Stewart (*Philos.* vol. ii., p. 279) as an instance of the ruinous effects of the scholastic logic. It is said by Clarendon that 'Chillingworth was a man of little stature,' and that it was 'an age in which many great and wonderful men were of that size.' The 10th and best ed. of *The Relig. of Protest.* is that in fol., 1742, with sermons, &c. and a life of the author by Dr. Birch. An edition of Chillingworth's whole works has been recently published in 1 vol., 8vo. For evidence that Chillingworth was not a Trinitarian, see Whitaker's 'Origin of Arianism,' p. 482, 492. A complete list of his miscellaneous controversial works is given in Kippis's *Biog. Brit.*, vol. iii., p. 515, and in the *Life of Chillingworth*, by Des Maizeaux, 8vo., 1725.

CHILOE, an island situated on the western coast of South America, between 41° 48′ and 43° 50′ S. lat., and 73° 20′ and 74 30′ W. long. It is the most northern of that series of larger and smaller islands which skirt the western coast of South America from Cape Horn northwards. It is divided from the continent by a wide strait, called the Gulf of Ancud, and at its northern extremity by the much narrower strait of Chacao. It extends from north to south about 120 miles, and from east to west sixty, where widest; but its eastern coast being deeply indented, the average width probably does not exceed forty miles. This gives an area of 4800 square miles. It is therefore nearly 900 square miles larger than Corsica, about 1000 square miles less than Yorkshire, or about double the area of Devonshire. The whole island is one mass of rock, which in no part rises to a great height, and is covered with earth and clothed with wood, chiefly consisting of a species of bastard cedar, very durable, and affording excellent timber, which is exported in great quantities to Chile and Peru. In the island itself it is used for building vessels. The northern and eastern coasts, which are much indented, have many excellent harbours, among which the best are Chacao, S. Carlos, Dalcahue, and Castro, in all of which vessels of any size may anchor with the greatest safety. On the west coast is the Lagoon of Cucao, which is upwards of twenty miles in length, and connected with the sea. Though frost and snow are hardly known, the climate of the island is chilly. The air is so damp that fogs occur almost daily during the rainy season, which lasts ten months; yet the climate is healthy. The domestic animals are cattle, horses, sheep, and swine. Some hides are exported, and also nearly 8000 hams annually, of excellent quality. These with about 260,000 planks constitute all the articles that are sent out. Sometimes grain is exported. The soil being of excellent quality produces rich crops of wheat and barley, and great quantities of potatoes. A good deal of butter is made, but it does not yet form an article of commerce. Fish, as well as oysters and other shell-fish, are very abundant, and in some parts are the chief food of the inhabitants.

The interior of the country is not known, the inhabitants living all along the sea-shore, or only at a little distance from it. The northern and eastern coasts are settled by Europeans, but at the southern extremity only Indians in small numbers are found. The people are in appearance more like northern Europeans than Spaniards, being athletic and robust, and having a fair complexion and light flaxen hair. The principal towns are S. Carlos, on the strait of Chacao, a small town with about 2000 inhabitants, and Castro, which is somewhat larger. The Gulf of Ancud contains a great number of smaller islands, of which about thirty-two are inhabited. The most remarkable are Quinchau, Lemuy, Calbuco, and Llaicha. On Lemuy very good ponchos are made from the wool of the country.

All these islands form together the Chiloë archipelago. They constitute the most southern of the provinces of Chile. This province includes also the small fortress of Maullin, which is situated on the mainland near the western entrance of the strait of Chacao, and is the most southern European settlement in America.

The province of Chiloë contained in 1832 a population of 43,382, and 31 schools, in which 1271 boys received instruction. It sends three representatives and two senators to the congress. (Poeppig's *Travels in Chili, Peru, &c.*, in German.)

CHILO'GNATHA, according to Latreille, a family of insects of the order of *Myriopoda*. Technical characters:—Body generally cylindrical, and consisting of numerous crustaceous rings or segments; the head is furnished with two short seven-jointed antennæ, and two mandibles; the horny substance of the mandibles does not continue uninterruptedly from the base to the apex, but is divided in the middle, so that the upper part is, as it were, hinged to the lower by a tough membrane; they are covered above by the fore part of the head, which forms a kind of upper lip, and beneath by an under lip; this last part is divided externally into four portions by three sutures; the two central portions are narrower than the outer ones, and spring from a plate of a semicircular shape; the apex of the under-lip is furnished with several large tubercles. The first segment of the body, or that next the head, is considerably larger than the following segments. The legs are short, very numerous, and terminated by a simple hook; the anterior segments of the body are, some of them, unprovided with legs, and others have a single pair each; the remaining segments (with the exception of the two or three last), commencing from the fourth, fifth, or sixth from the head, are each furnished with two pairs of legs.

The sexual organs of the male are situated behind the seventh pair of legs, and those of the female behind the second pair.

The respiratory orifices are situated on the sternal part of each segment of the body; they communicate internally with a double series of pneumatic sacs which extend the whole length of the body, and from which the tracheal branches spring, and spread over the other organs; these sacs are not connected with each other, as is usually the case, by a principal trachea.

A series of pores on each side of the body have been mistaken for the stigmata, but their orifices give vent to an acid liquid secretion which has a very disagreeable odour, and probably serves as a means of defence.

The chilognathæ crawl slowly and appear to glide over the ground; and when touched they will roll themselves up spirally. They feed upon decaying animal and vegetable substances, and constitute the genus Iulus of Linnæus. [IULUS.]

CHILOMANAS. [PHYTOZOARIA.]

CHILO'PODA, according to Latreille, a family of insects of the order *Myriopoda*. This family is synonymous with the order Syngnatha, Leach, and the genus Scolopendra of Linnæus. The characters are—antennæ thick at the base, and gradually growing slender towards the apex, composed of fourteen or more joints; the mouth consists of two mandibles, which are furnished with a palpiform process, and provided at the apex with numerous little denticulations; covering these is an upper lip and an under lip; the latter is composed of four distinct portions, of which the two outer parts are the largest, and transversely jointed: above this part (viewing the head from beneath) are two palpi, which resemble legs in being terminated by a pointed claw: covering this underlip, there is a second lip, an organ furnished with two lateral processes, each of which is terminated by a large bent claw, which is said to be perforated beneath by a hole through which a poisonous liquid is ejected.

The body is depressed, composed of numerous segments, which are covered above and beneath with plates of a horny substance, and each segment is generally furnished with a pair of legs; the last pair are thrown back. The sexual organs are placed at the posterior extremity of the body. The organs of respiration consist wholly or partly of tubular tracheæ. The stigmata are placed on the sides of the body.

These insects are carnivorous, and crawl about by night. Most of them are very active in their movements, and some emit a phosphoric light. They conceal themselves under stones and fallen trees, and are all found in rotten wood. In hot climates some of the species grow to an immense size (especially those of the genus Scolopendra, as it is now restricted), and, owing to their venomous bite, are much dreaded by the inhabitants of those parts.

The animals commonly known by the name of centipedes belong to this family. [SCOLOPENDRA.]

CHILTERN HUNDREDS. A portion of the high land of Buckinghamshire is known by the name of the Chiltern hills. 'Formerly these hills abounded in timber, especially beech, and afforded shelter to numerous banditti. To put these down, and to protect the inhabitants of the neighbouring parts from their depredations, an officer was appointed under the crown, called the steward of the Chiltern Hundreds;' (*Geography of Great Britain*, by the Society for the Diffusion of Useful Knowledge.) The duties have long since ceased, but the nominal office is retained to serve a particular purpose. A member of the House of Commons, not in any respect disqualified, cannot resign his seat. A member therefore who wishes to resign, accomplishes his object by accepting the stewardship of the Chiltern Hundreds, which being held to be a place of honour and profit under the crown vacates the seat. This nominal place is in the gift of the chancellor of the exchequer.

CHIMÆ'RA, a genus of cartilaginous fishes allied to the sturgeon and shark sections. [STURIONIDÆ.]

CHIMA'PHILA CORYMBO'SA (Pursh), the Pyrola umbellata of Linnæus, corymbose *Wintergreen*, a small evergreen woody plant, common in the pine-forests of the north of Europe, also found in Asia, and in North America, to the Indian inhabitants of which its virtues have been long known. The leaves possess diuretic properties joined to a tonic power, and they impart strength and comfort to the stomach while they increase the action of the kidneys. Applied externally, they cause redness and vesication of the skin. Chemical analysis shows them to consist of tannin, resin, and an acrid extractive. The taste is at first sweet, afterwards bitter. Their tonic and diuretic properties render them valuable remedial agents in dropsies, especially such as follow acute diseases. They have also been given advantageously in intermittent, and even typhus, fever. Dr. Chapman ascribes a diaphoretic power to them. Infusion, decoction, and extract are the forms in which they have been given: decoction is preferable, of which some ounces may be given repeatedly during the day. (See *Trans. of Medico-Chirurg. Society*, vol. v.)

CHIMAY. [HAINAULT.]

CHIMBORA'ZO, a mountain mass, forming one of the higher summits of the Andes. It is situated between 1° and 2° S. lat., and between 79° and 80° W. long., in the republic of Ecuador, nearly at an equal distance from the towns of Quito and Guayaquil. It is on the western of the two parallel ranges, which here constitute the highest portion of the whole chain. Its summit, as determined by Humboldt, rises nearly 21,600 feet above the level of the sea. The snow-line in the neighbourhood of the equator being about 15,750 feet, the summit of the mountain is 5850 feet, or more than one-fourth of its height elevated above it. Since the visit of the French mathematicians to Peru to measure a degree of the meridian, Chimborazo has been considered the highest summit in America, and generally on the globe. But towards the close of the last century it was ascertained that some of the summits of the Himalaya mountains rose to a greater height; and within the last ten years it has been proved that the highest portion of the Andes does not lie near the equator, but between 14° and 17° S. lat., where at least four summits rise higher than Chimborazo: the highest of them, the Nevado di Sorato, rises to 25,250 feet, or nearly 4000 feet higher than Chimborazo. (Humboldt; Pentland, in *London Geographical Journal*, vol. v.)

CHIMES, a set of bells tuned to the modern musical scale, and struck by hammers acted on by a pinned cylinder or barrel, which revolves by means of clock-work. The term is also applied to the music, the tune, produced by mechanical means from the bells in a steeple, tower, or common clock.

Chimes differ from Carillons (as the last word is commonly understood in England), inasmuch as the bells of the former are acted on by clock-work, those of the latter by keys struck by the hand. But the French apply the term *carillon* to the tune played, and, generally, to the series of bells, whether sounded by machinery or by hand; though the most accurate writers distinguish the latter kind as *le carillon à clavier*. The *carillons à clavier* comprise three octaves of bells, sounded by means of keys, similar to the pedals of an organ, which the performer strikes forcibly with hands clenched and sideways, the little fingers being guarded by a thick covering of leather. These keyed-carillons are found in many towns of Holland and the Netherlands. At Ghent they are remarkable; but the best specimen is at Amsterdam, where the *carilloneur* (M. Pothoff, formerly an organist in that city) used to display an extraordinary command of the instrument, on which he executed pieces in three parts—the base by means of pedals—with a rapidity rarely exceeded by judicious performers on the organ.

CHIMNEY. [HOUSE.]

CHIMNEY-SWEEPER, a person whose trade it is to cleanse foul chimneys from soot. The actual sweepers are boys, formerly of very tender age, who are taught to climb the flues, and who, from the cruelties often practised upon them by their masters, have, for the last half century, become objects of particular care with the legislature. The first and chief act by which regulations concerning them were enforced was the 28th Geo. III., c. 48. It has been since followed by Act 4 & 5 Will. IV., for the better regulation of Chimney-sweepers and their Apprentices, and for the safer Construction of Chimneys and Flues, passed 25th July, 1834. From that date no child who is under ten years of age can be apprenticed to a chimney-sweeper. The law is so tender with regard to these generally friendless children, that it has appointed a particular form of indenture for them. About the beginning of the present century, a number of public-spirited individuals joined in offering considerable premiums to any one who would invent a method of cleansing chimneys by mechanical means, so as to supersede the necessity of climbing-boys. Various inventions were in consequence produced, of which the most successful was that by Mr. George Smart. The principal parts of the machine are a brush, some hollow tubes which fasten into each other by means of brass sockets, and a cord for connecting the whole together. The unskilful use of the machine, however, and the antiquated and peculiar construction of a great many of the chimneys of the metropolis, have prevented the universal adoption of what had received the significant appellation of 'the last chimney-sweeper.' Till the passing of the last Act, the little chimney-sweeper used to announce his vocation as he traversed the streets of London by crying 'Sweep.'

CHIMONA'NTHUS, a Japanese genus of Calycanthaceous plants, whose species or varieties are called in the gardens Japan allspice. They are deciduous plants, with opposite pale-green, sharp-pointed, rather rough leaves, of an ovate-lanceolate figure. About the end of November these fall from the bushes, and are succeeded by the flowers, which appear at Christmas-time upon the naked branches. They consist of an inferior calyx, formed of a considerable number of roundish scale-like sepals, the outermost of which are pale brown, the innermost semi-transparent, with some tinge of yellow. The petals are yellowish ovate leaves, staind with chocolate red veins, and surrounding a small number of stamens. The fruit is a bright brown leathery calyx-tube, enclosing three or four oblong bright-brown polished nuts. There is probably no plant more deliciously fragrant than this, the orange and violet not excepted; the plant is quite hardy if protected a little by a wall or by palings. Three varieties are known in the gardens; the common kind with small pale-yellow flowers; the *grandiflorus* with large bright-yellow flowers; and another with flowers resembling those of the first, except in being very much smaller. The last is not worth cultivating; both the former should be found in every garden, however small; nothing can be more elegant as room ornaments than handsful of their round flowers placed on little porcelain trays.

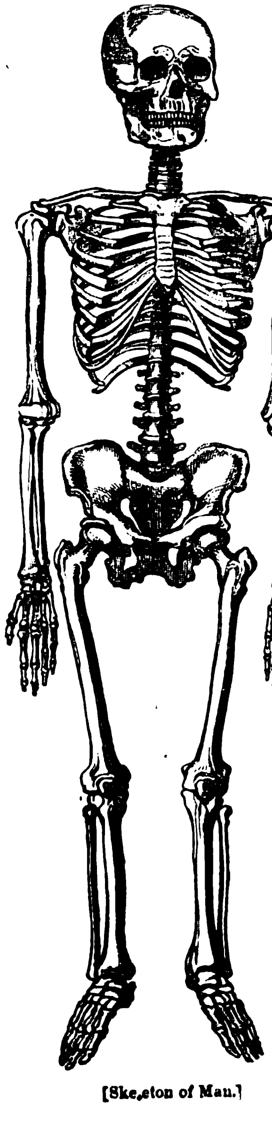
CHIMPANZEE, the name by which one of those forms which approach nearest to man is most generally known. The term has been applied to the *Simia Satyrus* of Linnæus, the *oriental orang*, but zoologists are now agreed in its proper application to the *Black* or *African Orang* or *Pygmy*. (*Troglodytes niger* of Geoffroy, *Simia Troglodytes* of Blumenbach.) Linnæus placed the form under the genus Homo, with the specific name *Troglodytes*, next to *Homo Sapiens*, arranging, as we have seen above, the Asiatic orang under the *Simiæ*; but he seems to have confounded the two species of orangs, which differ very considerably; for he refers to the figure given by Bontius which was intended for the Asiatic, and yet he gives, quoting Pliny, the borders of Ethiopia as its habitat, as well as Java, Amboyna, Ternate, and Mount Ophir in Malacca. That the Chimpanzee, though much of its organization bears a striking resemblance to that of man, is separated from him by a wide interval, the accurate investigations of modern anatomists sufficiently prove. Tyson, Camper, Blumenbach, Cuvier, Lawtence, and Owen, have set that question at rest, though Bory de St. Vincent struggled hard to retain man and the orangs as members of the same zoological family. Before we refer to the arguments of the last-named zoologist, it will be necessary to apprize the reader that, to say nothing of the difference of organization in other parts of the body and foot, the heel-bone (*os calcis*) of man does not project backwards so far in proportion as that of the Chimpanzee, and Lawrence notes this as an infallible human characteristic; '*ex calce* hominem.' Bory de St. Vincent, and those who support the theory of gradual development of animal form, endeavour to show that the position of the great toe, upon which its conversion into an opposable organ, or thumb, and the consequent transmutation of the foot into a hand, principally depends, is a character subject to modification; and, after a somewhat sweeping assumption, that it is the only difference of organization between the orangs and man, points the whole strength of his argument against its value as a zoological character; and, by a rather retrograde process of reasoning, endeavours to support his views by giving an instance where man, under certain circumstances, obtains a prehensile power of foot. Calling in aid the *Resiniers* of the landes of Aquitaine, he exhibits them as having acquired a power of opposing the great toe to the others, a faculty supposed to have been arrived at by their scansorial habits in obtaining their living, by gathering the resin of *Pinus maritima*. 'But,' as Owen well observes, 'supposing the extent of motion of the great toe to be sufficiently increased by constant habits of climbing, or in connexion with a congenital defect of the upper extremities, yet it does not appear that the *os calcis*, or the other bones of the foot, have lost any of those proportions which so unerringly distinguish man from the ape.' M. Bory, however, in his zealous endeavours to lower the arrogance which makes man unwilling to fraternize with apes and monkeys, is carried so far as to give vent to this naïve question. 'En effet, quatre mains ne vaudraient elles pas mieux que deux comme élémens de perfectibilité?' 'In fact, are not four hands of more value than two as elements of perfectibility?' Now let us look at this fallacy, for a fallacy it is. There might be a little, and a very little after all, in the query, if any one of the four hands of the *Quadrumana*, or all of them put together, approached the hand of man as an instrument of action,—an instrument whereby, though born the most helpless of animals and without clothing or any natural protection, he has made himself master of all, and compelled the apparently most impracticable natural productions to minister not only to his wants, but to his most luxurious imaginations. Let any one who is at all conversant with animal mechanics look at the hand of a chimpanzee, and compare it with his own; or let any one observe the chimpanzee using his apology for a thumb, and then cast his eyes on the merest hodman at his work, and he will soon see where the advantage lies. And this is not all. 'To give due force to this proposition,' says Owen in his excellent paper 'On the Osteology of the Chimpanzee and Orang Utan,' 'the four hands of the ape ought to be independent of any share in stationary support or progression; now, it is scarcely necessary to observe, that the perfection of the hands of man results, in a great measure, from the free use he is enabled to make of them in consequence of the organization of the lower members as exclusive instruments for sustaining and moving the body. It has, however, been suggested that the *hallux* (thumb) of the orang might acquire increased length and strength during the efforts of successive generations to maintain the erect position; but if we look a little further into the anatomy of the orangs, a difficulty presents itself unforeseen by Lamarck. The muscle called *flexor longus pollicis pedis* terminates, in the human subject, in a *single* tendon, and its force is concentrated on the great toe, the principal point of resistance in raising the body upon the heel. In the orang, however, the analogous muscle terminates in *three* tendons, which are inserted separately and exclusively in the three middle toes, obviously to enable these to grasp with greater force the boughs of trees, &c. It is surely asking too much to require us to believe that, in the course of time, under any circumstances, these three tendons should become consolidated into one, and that one become implanted into a toe, to which none of the three separate tendons were before attached. The myology of the orangs, to which I may hereafter endeavour to direct more attention than it has yet received, affords many arguments equally unanswerable against the possibility of their transmutation into a higher race of beings.' From the same author we take the following summary comparison of the *chimpanzee* and *orang utan* with each other, and with *man*.

The *chimpanzee* differs osteologically from the *orang*: 1. In having the cranium flatter and broader in proportion to the face. 2. In having the supraciliary ridges more developed, and in the absence of the interparietal and sagittal crests. 3. In the junction of the temporal with the frontal bones. 4. In the greater proportional breadth of the interorbital space. 5. In the more central position and less oblique plane of the occipital foramen. 6. In having but one anterior condyloid foramen on each side, while the orang has two. 7. In having generally but one suborbital foramen on each side, while the orang has three or more. 8. In the persistence of the cranial sutures. 9. In the earlier obliteration of the maxillo-intermaxillary sutures. 10. In the smaller proportional size of the incisive and canine teeth, and consequent smaller development of the jaws, especially of the intermaxillary bones. 11. In the smaller proportional size of the cervical, and larger proportional size of the lumbar vertebræ. 12. In the additional dorsal vertebra corresponding to the additional pair of ribs 13. In the more complete composition of the sternum which consists of a single and not double series of bones, as in the orang. 14. In the greater sigmoid curve of the clavicle, which in the orang is nearly straight. 15. In the less proportional breadth of the *scapula*, and the more lateral aspect of the glenoid cavity. 16. In the less proportional breadth and greater length of the *sacrum*. 17. In the less proportional breadth of the *ilium*, and greater expansion of the *ischium*. 18. In the comparative shortness of the upper extremities, more especially of the fore-arm and hand. 19. In the non-division of the pisiform bone of the wrist. 20. In the greater proportional length of the *femur* and *tibia*, and the less proportional length of the foot. 21. In the presence of a *ligamentum teres*, and consequent depression in the head of the *femur*. 22. In the greater proportional size of the *tarsus* as compared with the *phalanges* of the toes. 23. In having constantly two *phalanges* in the *hallux* or great toe with a nail, while the ungueal *phalanx* and nail are often wanting in the *hallux* of the orang, especially in that of the female.

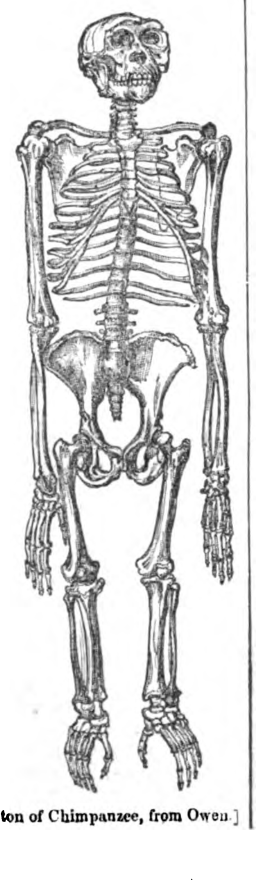
The *Chimpanzee* approximates more nearly to the human structure in those deviations which are numbered 4, 5, 6, 7, 8, 9, 10, 12, 13, 17, 18, 19, 20, 21, 22, 23.

The *Orang* has a nearer resemblance to *Man*: 1. In the junction of the sphenoid with the parietal bones. 2. In having 12 pairs of ribs. 3. In the form of the *scapula*, especially in its greater breadth.

Mr. Owen well observes, that it is a result of the preceding comparison, that the *Chimpanzee* ought to rank above the *Orang* in a descending series, and not below it as in the *Règne Animal* of Cuvier. Linnæus, as we have seen, gave the *Chimpanzee* that superiority of rank, but erred as much on the other side by placing it under the genus *Homo*, for both the *Chimpanzee* and *Orang*, according to Owen, differ in structure from the human subject. 1. In the *diastema*, or interval between the *cuspidati* and incisors in the upper jaw, and between the *cuspidati* and *bicuspides* of the lower jaw. 2. In the greater magnitude of the intermaxillary bones, indicated in the adult by the distance of the *foramina incisiva* from the incisive teeth, both of which differences result from the greater proportional development and different forms of the *cuspidati* and incisors. These, as the author observes, are differences of generic value. 3. In the more backward position and oblique plane of the occipital *foramen*. 4. In the smaller proportional size of the occipital condyles. 5. In the larger proportional size of the petrous bones. 6. In the greater proportional development of the jaws. 7. In the flatness of the nasal bone, which is rarely divided in the mesial line, while in *Man* the nasal bones are as rarely consolidated into one. 8. In the presence of the ant-auditory process of the temporal bone, and the absence of the mastoid and styloid processes. 9. In the absence of the process of the ethmoid, called *crista galli*. 10. In the shortness and comparative weakness of the lumbar region of the spinal column, which is also composed of four instead of five *vertebræ*. 11. In the narrowness and proportional length of the *sacrum*. 12. In the flatness of the *ilia*, and the larger development and outward curvature of the *ischia*. 13. In the position of the *pelvis* in relation to the spine. 14. In the larger proportional development of the chest. 15. In the greater length of the upper extremities. 16. In the wider interval between the *ulna* and *radius*. 17. In the shortness and weakness of the thumb, and narrowness of the hand in relation to its length. 18. In the shortness of the lower extremities. 19. In the greater proportional length and narrowness of the foot. 20. In the small size of the *os calcis*. 21. In the shortness and opposable condition of the *hallux*.

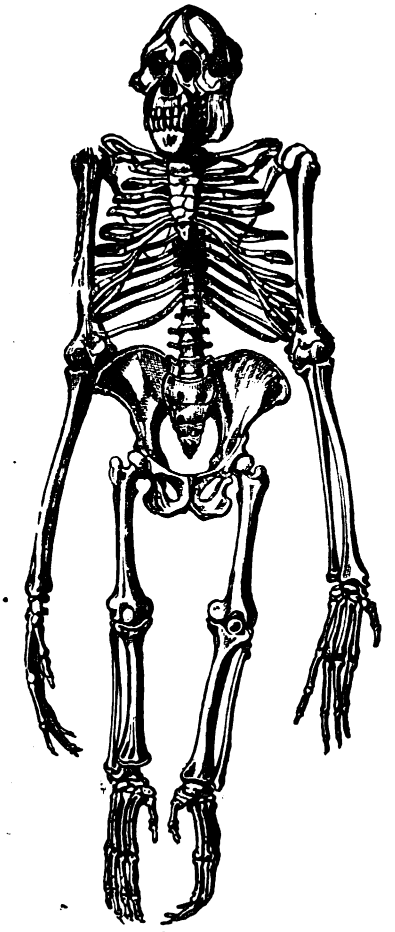


[Skeleton of Man.]



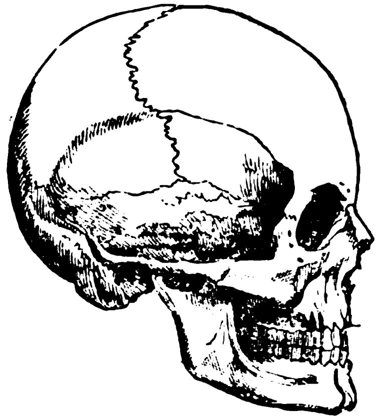
[Skeleton of Chimpanzee, from Owen.]

'These differences,' adds Mr. Owen, 'result from original formation, and are not liable to be weakened in any material degree, either on the one hand by a degradation of the human species, or, on the other hand, by the highest cultivation of which the anthropoïd *apes* are susceptible.'

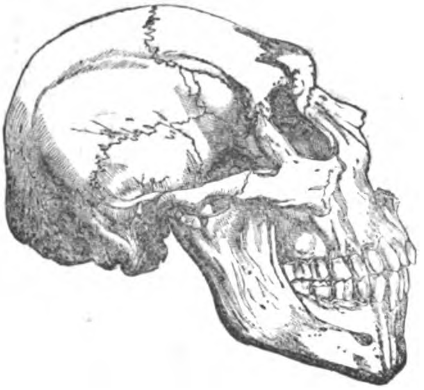


[Skeleton of Orang Utan, from Owen.]

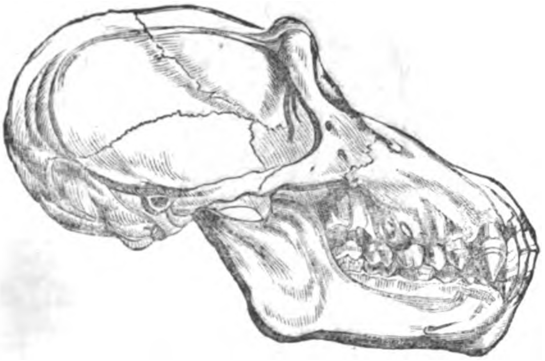
In following out this osteological comparison it becomes necessary, for the assistance of the student, to give a sketch of the cranial development in man, and in the anthropoïd apes, so that he may have under his eye the comparative form of each.



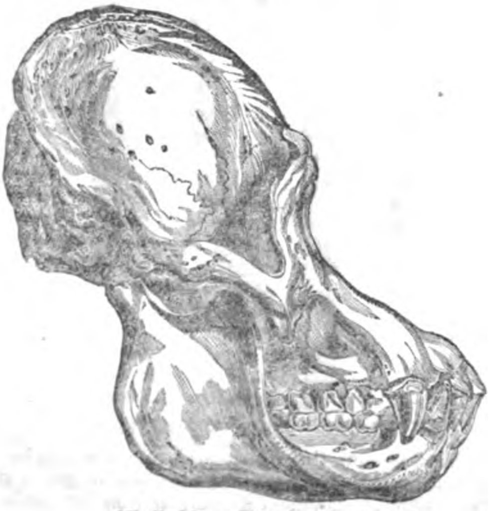
[Well-developed Human Skull.]



[Skull of Human Idiot, from Owen.]



[Skull of Chimpanzee, from Owen.]



[Skull of Orang Utan, from Owen.]

The following summing-up is so much better than anything we could present to the reader, that we give it in Mr. Owen's words.

'Certain modifications in the form of the human *pelvis* have been observed to accompany the different forms of the *cranium* which characterize the different races of mankind; but there is nothing in the form of the *pelvis* of the Australian or Negro which tends to diminish the wide hiatus that separates the *bimanous* from the *quadrumanous* type of structure in regard to this part of the skeleton. Observation has not yet shown that the *pelvis* of the *Orang*, in a state of captivity, undergoes any change approximating it towards the peculiar form which the same part presents in the human subject. The idea that the iliac bones would become expanded and curved forwards, from the pressure of the superincumbent *viscera*, consequent on habitual attempts at progression on the lower extremities, is merely speculative. Those features of the *cranium* of the *Orangs* which stamp the character of the irrational brute most strongly upon their frame, are, however, of a kind, and the result of a law originally impressed upon the species, which cannot be supposed to be modified under any circumstances, or during any lapse of time; for what external influence operating upon and around the animal can possibly modify in its offspring the forms, or alter the size, of the deeply-seated germs of the permanent teeth? They exist before the animal is born; and let him improve his thinking faculties as he may, they must, in obedience to an irresistible law, pass through the phases of their development, and induce those remarkable changes in the maxillary portion of the skull which give to the adult *Orangs* a more bestial form and expression of head than many of the inferior *simiæ* present. It is true that in the human subject the *cranium* varies in its relative proportions to the face in different tribes, according to the degree of civilization and cerebral development which they attain; and that in the more debased Æthiopian varieties, and Papuans, the skull makes some approximation to the *quadrumanous* proportions: but in these cases, as well as when the *cranium* is distorted by artificial means or by congenital malformation, it is always accompanied by a form of the jaws, and by a disposition and proportions of the teeth, which afford unfailing and impassable generic distinctions between *Man* and the *Ape*. To place this proposition in the most unexceptionable light, I have selected the *cranium* of a human idiot, in whom nature may be said to have performed for us the experiment of arresting the development of the brain almost exactly at the size which it attains in the *Chimpanzee*, and where the intellectual faculties were scarcely more developed; yet no anatomist would hesitate in at once referring this *cranium* to the human species. A detailed comparison with the *cranium* of the *Chimpanzee* or *Orang* shows that all those characters are *retained* in the idiot's skull which constitute the differential features of the human structure. The cranial cavity extends downwards below the level of the glenoid articulatory surfaces. The nasal bones are two in number, and prominent. The jaws and teeth exhibit the *bimanous* characters as strongly as in the most elevated of the human race. The *cuspidati* do not project beyond the contiguous teeth, and consequently there are no interruptions in the dental series, as in the *Orangs*, where they are required to lodge the disproportionate crowns of the canine teeth.'

M. Geoffroy St. Hilaire characterized the subgenus *Troglodytes* from immature *Chimpanzees*; and as Mr. Owen's observations were made upon the skeleton of an adult individual, and he has consequently altered the zoological characters given by Geoffroy, we follow Mr. Owen's definition.

Subgenus TROGLODYTES.

Dental formula, the same as in the human subject; viz., incisors $\frac{4}{4}$, canines $\frac{2}{2}$, bicuspids $\frac{4}{4}$, molars $\frac{6}{6}$. (N.B. The teeth approximate in their proportionate size much more nearly than those of the Orang to the human teeth; but they manifest in their relative position the absence of the character, which, with one anomalous exception—that of the fossil genus *anoplotherium*—is peculiar, among mammifers, to man; viz., unbroken proximity.)

Muzzle long, truncated anteriorly; strong supraciliary ridges, behind which the forehead recedes directly backwards; no cranial ridges.

Facial angle 35°, excluding the supraciliary ridges

Auricles, large.

Thirteen pairs of *ribs*; bones of the sternum in a single row.

Arms reaching below the knee-joint.

Feet wide; hallux extending to the second joint of the adjoining toe.

Canines large, overpassing each other; the *apices* lodged in intervals of the opposite teeth.

Intermaxillary bones anchylosed to the maxillaries during the first or deciduous dentition.

Example. The *Chimpanzee*, *Black Orang*, or *Pygmy* (*Troglodytes niger* of Geoffroy, *Simia Troglodytes* of Blumenbach). In the young state the animal has been named *Jocko*.

Description. The following is from the pen of Dr. Traill, of Liverpool: and from minute examination of the individual lately exhibited at the garden of the Zoological Society, in the Regent's Park, London, we can vouch for its accuracy. Dr. Traill's specimen was a young female, about thirty inches high, and was brought home by Captain Payne. 'The skin appears of a yellowish-white colour, and is thinly covered with long black hair on the front; but it is considerably more hairy behind. The hair on the head is rather thin, and is thickest on the forehead, where it divides about an inch above the orbital process of the frontal bone, and, running a little backwards, falls down before the ears, forming whiskers on the cheeks. Here the hair measures nearly two inches long; but that on the occiput is not above an inch in length. There are a few stiff black hairs on the eyebrows, and a scanty eyelash. A few whitish hairs are scattered on the lips, especially on the under one. The rest of the face is naked, and has whitish and wrinkled skin. There is scarcely any hair on the neck, but, commencing at the nape, it becomes somewhat bushy on the back. The abdomen is nearly naked. The hair on the back of the head, and the whole trunk, front of the lower extremities, back of the legs, and upper part of the superior extremities, is directed downwards, while that on the back of the thigh and fore arms is pointed upwards, appearances well represented in Tyson's figure. The longest hair is just at the elbows. There is none on the fingers or palms of either extremity. The ears are remarkably prominent, thin and naked, bearing a considerable resemblance in shape to the human, though broader at the top. The projection of the process above the eyes is very conspicuous, but has not been sufficiently marked in any engraving or drawing which has fallen under my observation. The nose is quite flat, or rather appears only as a wrinkle of the skin, with a slight depression along its centre. The nostrils are patulous, and open upwards, which would be inconvenient did the animal usually assume the erect posture. The projection of the jaws is excessive, and though much less so than in the baboon, yet the profile of the face is concave. It may be remarked however that the projection of the lower jaw is caricatured in the first and second figures of Camper's second plate. The mouth is wide, the lips rather thin, and destitute of that recurvation of the edges which adds so much to the expression of the human countenance. The spread of the shoulders is distinctly marked, but the width of the lower part of the chest is proportionally greater, when compared to the upper, than in man. From the lower ribs the diameter of the abdomen decreases rapidly to the loins, where the animal is peculiarly slender; a circumstance in which it approaches the other *Simiæ*. The pelvis appears long and narrow, another approximation to the rest of the genus. With regard to the limbs, the chief difference between our specimen and Dr. Tyson's figure consists in the excessive length of the arms, which in this animal descend below the knees, by the whole length of the phalanges of the fingers, which are above three inches in length. The same observation applies to almost every figure of this animal which I have seen. The proportions in the work of Camper approach nearest, in the present instance, in this particular. The hand differs from the human in having the thumb by far the smallest of the fingers. The foot is more properly a hand appended to a tarsus. The thumb of this extremity is very long, powerful, and capable of great extension. The legs are certainly furnished with calves; but they scarcely resemble the human in form, because they are continued of equal thickness nearly to the heel. When this animal is erect, the knees appear considerably bent, as is the case with the other *Simiæ*, and it stands with the limbs more apart than man.'

Geographical distribution. Africa is the only part of the world known to be the residence of the Chimpanzee, which, it should be remembered, has been confirmed, as Cuvier observes, by almost all zoologists. The specimen described by Dr. Traill was procured in the isle of Princes, in the gul of Guinea, from a native trader, who had carried it thither from the banks of the Gaboon. The individual exhibited in the Egyptian Hall, Piccadilly, in 1831, had been obtained by a trading vessel on the river Gambia, and that exhibited at the garden of the Zoological Society was brought from the Gambia coast. Cuvier gives Guinea and Congo as its localities. The subject of Mr. Owen's paper was shot by a European at Sierra Leone.

Habits. The habits of the Chimpanzee in a state of nature are but imperfectly known. Cuvier states that the Chimpanzees live in troops, construct themselves huts of leaves, arm themselves with sticks and stones, and employ these weapons to drive man and the elephant from their dwellings. He also repeats the story of their pursuit of the negresses and carrying them off into the woods. This report is, as we shall presently see, still credited in the country where they are found. Speaking of Captain Payne, Dr Traill, in his interesting paper in the Wernerian Transactions, says, 'The natives of Gaboon informed him that this species attains the height of five or six feet; that it is a formidable antagonist to the elephant; and that several of them will not scruple to attack the lion and other beasts of prey, with clubs and stones. It is dangerous for solitary individuals to travel through the woods haunted by the orang, and instances were related to Captain Payne of negro girls being carried off by this animal, who have sometimes escaped to human society after having been for years detained by their ravishers in a frightful captivity. These reports confirm the narratives of the early voyagers, who have often been suspected of exaggeration, and similar facts have been recently stated, very circumstantially, by gentlemen who have lived in western Africa.'

In a state of captivity its manners have been the theme of many a tale, and much admiration; and as most of the individuals described have died very young, conjecture has been busy as to the progress the animal might make if its education were continued to the adult state. 'Deductions,' says Mr. Owen in his paper above referred to, 'in favour of the anthropomorphous character of the orangs have been derived from observation of the living habits of young orangs; but these cannot be regarded as affording a type of the nature of the adults, since it is well known that the docility and gentle manners of the young ape rapidly give way to an unteachable obstinacy and untameable ferocity in the adult; at least of those species to which, as I shall afterwards show, the full-grown orangs have the nearest resemblance in the form of the head.'

Captain Payne thus describes the manners of the animal which formed the subject of Dr. Traill's paper. 'When our animal came on board,' says Captain Payne, 'it shook hands with some of the sailors, but refused its hand, with marks of anger, to others, without any apparent cause. It speedily however became familiar with the crew, except one boy, to whom it never was reconciled. When the seamen's mess was brought on deck, it was a constant attendant; would go round and embrace each person, while it uttered loud yells, and then seat itself among them to share the repast.' It sometimes expressed its anger by a barking noise like a dog; at others it would cry like a froward child and scratch itself most vehemently. When any favourite morsel was given to it, sweetmeats more especially, it expressed its satisfaction by a sound like 'hem,' in a grave tone. The variety of its tones seems to have been small. It was active and cheerful in warm latitudes, but languor came on as it left the torrid zone; and on approaching our shores, it manifested a desire for a warm covering, and would roll itself carefully up in a blanket when it went to rest. It generally progressed on all fours, and Captain Payne particularly observed that it never placed the palms of the hands of its anterior extremities on the ground, but, closing its fists, rested on the knuckles. This mode of progression noticed by Tyson was confirmed to Dr. Traill by a young naval officer who had been for a considerable time employed in the rivers of western Africa, and had opportunities of observing the habits of this species. Captain Payne's animal did not seem fond of the erect posture, which it rarely affected, though it could run nimbly on two feet for a short distance. In this case it appeared to aid the motion of its legs by grasping the thighs with its hands. It had great strength in the four fingers of its superior extremity; for it would often swing by them on a rope upwards of an hour without intermission. When first procured, it was so thickly covered with hair, that the skin of the trunk and limbs was scarcely visible, until the long black hair was blown aside. It ate readily every sort of vegetable food; but at first did not appear to relish flesh, though it seemed to have pleasure in sucking the leg-bone of a fowl. At that time it did not relish wine, but afterwards seemed to like it, though it never could endure ardent spirits. It once stole a bottle of wine, which it uncorked with its teeth, and began to drink. It showed a predilection for coffee; and was immoderately fond of sweet articles of food. It learned to feed itself with a spoon, to drink out of a glass, and showed a general disposition to imitate the actions of men. It was attracted by bright metals, seemed to take a pride in clothing, and often put a cocked hat on its head. It was dirty in its habits, and never was known to wash itself. It was afraid of fire-arms; and on the whole appeared a timid animal. It lived with Captain Payne seventeen weeks, two of which were spent in Cork and Liverpool. At the former place it was exhibited for the benefit of the soup-kitchen for a few days, but seems to have been there neglected. On coming to Liverpool it languished a few days, moaned heavily, was oppressed in its breathing, and died with convulsive motions of the limbs. Such is Dr. Traill's account.

We also refer to the observations on the habits, &c., of a male chimpanzee (*Troglodytes niger*, Geoff.), then living in the menagerie of the Zoological Society of London, by Mr. Broderip, which were read at a meeting on the 27th of October, 1835[*].

The animal that was the subject of Mr. Broderip's remarks died in the spring of the following year; and on the 12th of April, 1836, Mr. Owen detailed the morbid appearances observed on its dissection[*]

[Troglodytes niger.]

Before we conclude this article, it may be necessary to hint at the probable height of the adult chimpanzee. The natives of Gaboon, as we have seen, informed Captain Payne that the species attained the height of five or six feet. Bingley, in his 'Animal Biography,' says, 'Allemand, the Dutch professor of natural history, had received many vague and unsatisfactory accounts respecting an animal of this kind, and was induced to write to Mr. May, a captain in the Dutch naval service stationed at Surinam. This gentleman found him exactly similar to one which he had brought from Guinea, except in size. He was nearly five feet and a half high, and very strong and powerful. Mr. May had seen him take up his master, a stout man, by the middle, and fling him from him for a pace or two; and one day he seized a soldier, who happened to pass carelessly near the tree to which he was chained, and, if his master had not been present, he would actually have carried the man into the tree.' It is further stated that the age of this animal, when Mr. May saw it, was about twenty-one years. In the following year it died, but was said to have increased in height during the interval. The mother of that exhibited in the menagerie of the Zoological Society was reported to have stood four feet six inches in height: but Mr. Owen gives three feet ten inches as the length of the body in the adult chimpanzee (skeleton), from the *vertex* to the base of the *os calcis*, and four feet as the height of the adult at the end of his subgeneric character.

CHINA is an extensive country in Eastern Asia, constituting the principal portion of the Chinese empire. It is situated on the borders of the Pacific, and extends from 20° N. lat., or, if the island of Hainan is included, from 18° to 41° N. lat., and if the tract of land projecting on the north-west towards the centre of Asia be added, to 46° N. lat. Its eastern extremity, where it borders on Corea, is cut by 124° E. long., and its western, where it borders on the Birman empire, by 98° E. long.; but if the projecting tract be added, it reaches to 85° E. long. Its greatest length, from the harbour of Amoy, opposite the island of Formosa, taken in a north-western direction to the farthest extremity of the projecting tract, can hardly fall short of 2000 miles. If, however, this latter tract is excluded, the length of China from the Peninsula opposite the island of Hainan to the great wall due north of Peking is about 1400 miles: its breadth varies between 900 and 1300 miles. If its average length is taken at 17 degrees of lat., or about 1180 miles, and its average breadth at the same number of miles, the area of China is 1,292,400 square miles, a computation which does not differ much from that of Sir George Staunton, who assigns to it 1,297,999 square miles, or an area more than eleven times as large as that of the British Islands. The north-western projecting tract is not included in both calculations.

China is surrounded by countries dependent upon it, except at its south-western and southern side, where it borders on the Birman empire, the kingdom of Siam, and that of Cochin China, of which the last only seems to be nominally dependent on China. On the west of it extend Tibet and the country of Kho-kho-nor, or Ching-Hai. The projecting tract is mostly surrounded by Eastern Turkistan, lately called Grand Tartaria, and by Mongolia. Mongolia occupies also the greatest part of its northern boundary, except in the extreme east, where it is bounded by Manchuria or Ching-King and by Corea. Its eastern side is washed by the Pacific, which forms a deep gulf between China and Corea, called the Hoango-Hai or Yellow Sea; it assumes the name of Tung-Hai or Eastern Sea, between Corea and the island of Formosa, and that of Nan-Hay or Southern Sea, between Formosa and Hainan.

Its coast being about 2440 miles, there is only one mile of coast for every 532 square miles. Where China borders on Corea its coast is high and bold, and full of rocky islets. This coast continues on both sides of the Peninsula of Leao-tung, or about 240 miles. It is followed by a sandy coast, which in most places is so low that it cannot be seen at a short distance from the shore: this coast extends from the innermost corner of the bay of Leao-tung for about 360 miles to the neighbourhood of the Straits of Meao-toa, which form the entrance of the bay of Pe-tsche-li. The coast of the Peninsula of Chan-tung is rocky, and commonly bold, but not high, except in a few places. It extends from the Straits of Meao-toa to Cape Macartney, and hence to 35° N. lat., about 350 miles. The shores, as far as the Chusan Islands (30° 30′ N. lat.), are low and sandy, indeed in many places very swampy, and extend from 420 to 450 miles. From the Chusan Islands to the bay of Canton the coast is rocky, bold, and high, except in the recesses of the numerous bays and harbours. At some places it rises to a considerable height, and is besides lined with numerous cliffs and rocky islets, in all its extent of about 800 miles. The western shores of the bay of Canton, for about 30 miles, are formed by a great number of low sandy islands. From the bay of Canton to the peninsula of Lui-cheou, about 120 miles, the coast is again rocky and bold, but it does not appear to be high. The shores of the peninsula itself are about 100 miles long, sandy, flat, and low; the remainder of the coast of China, which is washed by the Gulf of Tonkin (about 100 miles), is not well known.

---

[*] Proceedings of the Zoological Society of London, 1835, 1836.

A considerable portion of China is covered with mountains. Its western boundary extends to the chains which constitute the eastern edge of the high table-land of Eastern Asia [Asia and Bayan Khara]; but only the most eastern of these ranges lies within the boundary of China. It may be considered as beginning in the most southern bend of the Yang-tse-kiang, between 101° and 103° E. long., and as extending hence in a N.N.E. direction, and terminating in the great northern bend of the Hoang-ho, between 107° and 111° E. long. This mountain-range, which is called Siue-ling (Snow-range), or Yung-ling, contains a considerable number of snow-capped summits. The snowy mountains are numerous between 30° and 36° N. lat., and more especially between 32° and 34°. But even south of the great southern bend of the Yang-tse-kiang, and at a short distance from its banks, are some snow-covered summits, whence Ritter rightly concludes, that the river breaks through the southern portion of the range. The four mountain-chains, which traverse China from west to east, may be considered as offsets of this range. South of the snowy mountains, which are situated on the south of the great bend of the Yang-tse-kiang, is the hilly table-land of Yunnan. It is of considerable extent, and at a great elevation above the sea, if we may judge from its temperature in summer. From the eastern edge of this table-land two mountain-ranges branch off, the Yu-ling and the Nan-ling. The Yu-ling, the most southern of these ranges, branches off from the table-land in 24° N. lat. and 102° E. long., and runs nearly east to the neighbourhood of the bay of Canton, dividing the river Ta Si-kiang from the sea. It does not seem to approach the shores of the sea in any point, nor to rise to a great height. The Nan-ling (or southern range) which constitutes the most extensive mountain-system in China, branches off from the northern edge of the table-land of Yun-nan, where the snowy mountains are situated (26° N. lat. and 103° E. long.), and runs eastwards, passing about 150 miles to the north of Canton as far as 116° E. long.; it then inclines to the north-east, in which direction it continues with a slight bend to the west to its termination on the sea near the harbour of Ning-po, opposite the islands of Chusan. Several summits of this range rise above the snow-line, west of 110° E. long., where also it extends to a great width. An aboriginal nation, the Mioatsee, have maintained their independence in its fastnesses. A lateral range, which separates the Yang-tse-kiang from its tributary the Yuen-kiang, and extends north-east to the centre of China, is also said to contain some summits which rise above the snow-line. East of 110° no snow-capped mountains occur, though some rise to a great elevation; but even here the range preserves its steep and rugged character. Its numerous branches, running towards the Formosa Strait and the Tung-Hai, are also steep and craggy, but those extending northward are of inconsiderable elevation. Three mountain-passes are known to traverse the Nan-ling. The most frequented is to the north of Canton, where the range is called Mei-ling (the chain of the wild plum-trees, according to Klaproth), and hence the pass is called Mei-ling pass. By this pass goods are transported from Canton into the interior of China. Goods are brought in boats on the river Pe-kiang to the town of Nan-yong-foo. Between this town and that of Nan-gan-foo is the pass where goods are carried on the backs of men, for about 24 miles over rocky mountains. This is the only place, between Canton and Peking, where no water communication exists; for at Nan-gan-foo the goods are again shipped and descend the Kan-kiang and afterwards the Yang-tse-kiang till they come to the great canal. The elevation of the Mei-ling mountain-pass is estimated by Staunton to be 8000 feet above the sea. The second pass which is known occurs near 28° N. lat. and 118° E. long. between Kien-ning-foo on the east and Kian-tchang-foo on the west of the range, and though the mountains are very steep and rugged it is much frequented; 18,000 porters are continually employed for the transport of goods. The third road, which is a little farther north, connects the town of Kien-ning-foo with the town of Kin-tcheou-foo, which lies on the west of the range. Though difficult to pass it is much used.

The two other mountain-ranges, the Tapa-ling and the Pe-ling, are immediately connected with the Yun-ling, the Tapa-ling branching off south of 33° N. lat. and Pe-ling about 35°. The Tapa-ling runs south of east nearly in a straight line, and terminates near 112° E. long. north-east of the town of Koei-tcheou-foo. It divides the valley of the Han-kiang from that of the Yang-tse-kiang, and rises to a great height; several of its summits exceed the snow-line, as, for instance, the Kianku Shan, with which it terminates. The Pe-ling, which runs nearly parallel to the Tapa-ling, separates the valley of the Han-kiang from that of the Hoai-ho, or Wei-ho, an affluent of the Hoang-ho, and consequently the two great river-systems of China from one another. It continues in its eastern direction to 113° E. long., and this portion of the range is high, rugged, and steep. At 113° it declines to the south-east, diminishing considerably in elevation and ruggedness. Having attained 32° N. lat. it turns again to the east, and soon subsides into a chain of hills, which terminates on the western shores of the lake Tsiao-hoo, a considerable distance east of Nanking. The western part this range contains several snowy mountains, though fewer than the Tapa-ling. The obstacles opposed by these two chains to the communication between the provinces which they traverse have been overcome by an artificial road, much more extensive than those which traverse the Alps. Beginning at the antient capital of Singan-foo on the banks of the Hoai-ho it runs in the valley of that river west past Fong-tsiang-foo to a place named Pao-ki-hiang. Near this place begins the mountain-road which is conducted over deep clefts by long bridges, and is often deep cut through high mountains. It then descends from the Pe-ling to the valley of the Han-kaing, which it crosses about 20 miles west of the town of Hang-tchong-foo. It then traverses the Tapa-ling, on the south of which it terminates on one of the branches of the Kialing-kiang at Tchao-hoa, north of Kian-tcheou-foo. This artificial mountain-road is said to be 420 lis or nearly 150 miles long. Its continuation leads through a less mountainous country, traverses the town of Poa-king-foo, and terminates at the antient capital of Tching-tu-foo.

These ranges traverse that part of China which lies south of the Hoang-ho. But even the western, and greater portion of the countries north of that river is almost entirely covered with high and rugged mountains. These mountains belong partly to the northern portion of the Yun-ling, which joins the Hoang-ho at its great bend, and partly are ramifications of the Inshan, a range which extends round the bend of the river on the west and north, and whose offsets enter China between that bend and the town of Peking in several ridges.

The whole surface of China may be divided into the mountainous country, the hilly country, and the great plain. The mountainous country comprehends more than half of the whole, and the meridian of 112° may be considered its eastern boundary, but to the north of the Hoang-ho it extends as far as 114°. All this immense tract of country is covered by mountains and valleys. The mountains are commonly too steep and rugged to admit much cultivation, but a great part of them is covered with high trees. Towards the north they are mostly bare, but contain immense beds of coal. The valleys are often narrow, but being watered by numerous streams, their fertile soil maintains a numerous population. This general description, however, applies properly, in all its extent, only to the districts north of the Tapa-ling and south of the Nan-ling, for in those between these two ranges the mountains are less steep, and their sides are commonly cultivated to a considerable height. The valleys, too, are much wider, and the level land sometimes extends to plains of considerable width, as, for instance, the plain of Tching-tu-foo, which is perhaps 20 miles in every direction.

Among the mountainous districts must be included the tract of land which lies between the Nan-ling and the sea; but, with the exception of the immediate neighbourhood of the range, it rather resembles the countries between the Nan-ling and Tapa-ling than those farther north, its valleys being generally wide, and sometimes expanding into plains, as, for instance, the plain of Canton. A considerable portion of the sides of the mountains is also fit for cultivation. If this tract is added to the other mountainous country, it may be said, that rather more than two-thirds of the surface of China are of this character.

The hilly country lies to the east of 112° E. long., and between this meridian and the eastern part of the Nan-ling, and extends north to the banks of the Yang-tse-kiang. The hills, though in many places steep, generally rise with a gentle ascent; and, as they do not attain a great elevation, their sides are cultivated, and planted with rice on the terrace system. Their tops are covered with forest trees, generally of the pine kind, which are carefully planted. The levels between the hills are sometimes narrowed into valleys, in other places they expand into plains. They have generally abundance of water in their rivers, and there are some lakes, of which the largest are the Tung-ting near the confluence of the Yuen-kiang with the Yang-tse-kiang, and the Po-yang, not far from the mouth of the Kan-kiang. The greatest portion of the surface is in a very high state of cultivation.

The great plain occupies the north-eastern part of China. It extends in length 700 miles from the Great Wall, north of Peking, to the confluence of the rivers Yang-tse-kiang and Kan-kiang (30° N. lat.). The Yang-tse-kiang may be considered as its southern boundary, as far down as Ngan-king, whence to the sea it is formed by a line drawn from Ngan-king to the sea, through Hang-tcheou-foo. The western boundary-line may be marked by a line drawn from King-tcheou-foo, a town situated on the Yang-tse-kiang, to Hoai-king-foo, on the Hoang-ho, and hence to the Great Wall, about 50 miles north-west of Peking. The breadth of the plain is various. North of 35° N. lat., where it partly extends to the shores of the Hoang-hai, and partly borders on the western side of the mountain range of Chang-tung, which occupies the peninsula of that name, its width varies between 150 and 250 miles. If we suppose the average breadth to be 200 miles, this portion of the plain covers an area of 70,000 square miles. Between 35° and 34° N. lat. the plain enlarges, and in the parallel of the Hoang-ho it extends more than 300 miles east and west. It grows still wider to the south, and reaches nearly 500 miles inland in the parallel of the embouchure of the Yang-tse-kiang. If we suppose the mean breadth of this portion of the plain to be 400 miles, it occupies a surface of 140,000 square miles. The whole plain, containing 210,000 square miles, is seven times as large as that of Lombardy, with which it may be compared in many respects.

The northern part of the plain has a dry sandy soil, impregnated in many parts with saline matter, and destitute of trees, but it produces millet and wheat in abundance. South of 35° N. lat. the whole tract along the coast is very low and swampy, being partly covered with numerous lakes and lagunes, and intersected by numerous water-courses, both artificial and natural. It produces a great quantity of rice. Farther inland the soil is more firm and dry, and of great fertility, which is increased by the abundance of water drawn from the rivers and small lakes. It produces rice, cotton, wheat, and tobacco. The southern districts bordering on the banks of the Yang-tse-kiang differ from the other in not being a flat level, but having a surface slightly undulating, on which even a range of hills rises, as the eastern prolongation of the Pe-ling. It is not, however, less fertile than the other districts. Among its most valuable branches of agriculture is tea, which is extensively cultivated on those low hills (between 30° and 32° N. lat.)

The eastern portion of this plain is traversed by the Great or Imperial Canal, which begins on the south at the town of Hang-tcheou-foo (30° N. lat.), and extends to the town of Lin-tchin-cheou, where it falls into the river Eu-ho or Wei-ho. Its length considerably exceeds 500 miles in a straight line, and probably its whole length may be 700. Some portions of it have been made merely for the purpose of internal navigation, but in others the design of draining and irrigating the adjacent country has been connected with it; hence it differs widely from all the canals made in Europe. Its breadth is considerably greater, and its waters are in few places altogether without a current. At a few points it is cut through rocks; it often traverses lakes and swamps of considerable extent, running on an artificial elevation, sometimes 20 feet above the surface of the country. Its flood-gates, bridges, the vessels which navigate it, and the number of towns and villages lining its banks, excite the admiration of all travellers. By this canal, and the navigable rivers, Yang-tse-kiang and Kan-kiang on the south, and the rivers Eu-ho and Pei-ho in the north, goods may be transported by water from the foot of the Mei-king pass to the town of Tong-tcheou-foo, a few miles distant from Peking. That portion of the canal which lies south of the Hoang-ho was made in the seventh century, or soon after, but the more northern part in the thirteenth, by Kublai Khan and his successors, when the Tartar dynasty had removed the imperial residence from Nanking to Peking.

The fertility of its soil and the advantages resulting from the internal navigation afforded by the Great Canal and its numerous branches, have rendered this plain the most populous spot on the earth. According to the census of 1813, the provinces which it comprises contained a population of 177 millions, namely, Pe-tshe-li 28, Chantung 29, Honan 23, An-hoei, or Ngan-hoi, 34, Kiang-su 37, and Che-kiang 26. Here then, as Ritter observes, lives a population more than two-thirds of the whole population of Europe. To protect this rich plain the Great Wall was erected, which incloses China on the northern boundary, and extends over mountains and rivers for about 1400 miles. This great work was constructed rather more than 2000 years since, or about 200 years before the Christian æra, by the first universal monarch of China, as a defence against the nomadic tribes of Tartars, who have never ceased to infest the country to the south, as long as it has been subject to a separate dominion. The main substance of the wall is earth or rubbish, retained on each side by a thick casing of stone and brick, and terraced by a platform of square tiles. It bounds the whole north of China, extending along the frontiers of three provinces, a distance of nearly 19° of longitude. From its eastern extremity there is an extensive stockade of wooden piles, enclosing the country of Mougden, and which in some European maps has been erroneously represented as a continuation of the solid barrier. The total height of the wall, as observed by an engineer officer in Lord Macartney's embassy, is 20 feet, on a basis of stone projecting 2 feet under the brick-work, and about the same in height. The thickness of the whole wall at the base is 25 feet, diminishing to 23 at the platform. The towers are 40 feet square at the base, diminishing to 30 at the top, and about 37 feet in height. The thinness of the parapet of the wall, being only 18 inches, justifies the conclusion that it was not intended to resist cannon; and it appears certain that the use of fire-arms is comparatively modern in China, however antient the invention of gunpowder.

Numerous rivers drain and water China, but by far the greater number flow into the HOANG-HO and YANG-TSE-KIANG, which are among the greatest rivers of the globe. Among the rivers which do not belong to the systems of those two great rivers, two require notice here, the Pei-ho and the Ta-si-kiang. The Pei-ho or White River rises on the mountains north-west of Peking, near the Great Wall, and flows in a south-eastern direction to the town of Tong-tcheou-foo, a few miles east of Peking, where it becomes navigable for large river-boats. Continuing in the same direction, it unites with the Eu-ho, a much larger river than the Pei-ho itself, which rises near the banks of the Hoang-ho, and running in a north-east direction is connected with the Great Canal at the town of Lin-tchin-tcheou: the remainder of its course may be considered as the continuation of the canal. The tides come up nearly to the place where the Eu-ho meets the Pei-ho, a distance of more than eighty miles. Hence to the sea the Pei-ho runs nearly due east, and at its mouth has a bar which at low tides has only two or three feet water upon it; but at high tides, which here rise five or six feet, the bar does not prevent the flat-bottomed Chinese junks from entering the river. There is perhaps no river in the world which is navigated by so many vessels as the Pei-ho.

The Ta-si-kiang, or the river of Canton, rises east of the town of Yunnan (103° E. long.), and runs the first half of its course in a narrow valley between high mountains, and the other half in a wide, fertile, and well-cultivated one; towards its mouth it drains the plain of Canton, and receives the Pe-kiang. The general direction of its course is from west to east, and it seems to be navigated to a considerable distance.

Climate.—In regard to the climate of China, a distinguishing feature is the unusual excess in which heat and cold prevail in some parts of the empire at opposite seasons of the year; as well as the low average of the thermometer in comparison with the latitude. Although Peking is nearly a degree to the south of Naples, the latitude of the former place being 39° 54′, of the latter, 40° 50′, the mean temperature of Peking is only 54° of Fahrenheit, while that of Naples is 63°. But as the thermometer at the Chinese capital sinks much lower during the winter than at Naples, so in summer it rises somewhat higher. The rivers are said to be frozen for three or four months together, from December to March; while, during the last embassy in September, 1816, a heat of between 90° and 100° was experienced in the shade. It is well known that Naples and other countries in the extreme south of Europe are strangers to such a degree of long-continued cold, and are not often visited by such heats. Europe, observes Humboldt, may be considered altogether as the western part of a great continent, and therefore subject to all the influence which causes the western sides of continents to be warmer than the eastern; and at the same time more temperate, or less subject to excesses of both heat and cold, but principally the latter. The mean annual temperature of Canton and Macao, which lie nearly under the tropic, is what commonly prevails in the 30th parallel; and it is surprising to contrast their meteorological averages with those of Calcutta, which stands very nearly in the same latitude*. The total fall of rain varies greatly from one year to another; the average annual quantity is about 70 inches, but it has been known to reach 90 inches and upwards. Vegetation is checked in the interval from November to February, not less by the dryness than by the coldness of the atmosphere: the three winter months being known sometimes to elapse with scarcely a drop of rain. The north-east monsoon, which commences at Canton and in the adjacent seas to the southward and eastward in September, blows strongest from December to February, and begins to yield to the opposite monsoon in March or April. About that period the southerly winds come charged with the moisture which they have acquired in their passage over the sea through warm latitudes; and this moisture is suddenly condensed into thick fogs as it comes in contact with the coast of China, which has been cooled down to a low temperature by the long-continued northerly winds. The latent heat given out by the rapid distillation of this steam into fluid, produces the sudden advance of temperature which takes place about March; and its effect is immediately perceptible in the stimulus given, by this union of warmth with moisture, to vegetation of all kinds. With the progressive increase of heat and evaporation commence those rains which tend so greatly to mitigate the effects of the sun's rays in tropical climates. In the month of May the fall of rain has been known to exceed twenty inches, being more than a fourth of all the year, and this keeps down the temperature to the moderate average of about 75°, while in Calcutta there is no portion of the year more dreaded than May. At length the increasing altitude of the sun, which becomes just vertical at Canton about the solstice, and the accumulated heat of the earth, bring on the burning months of July, August, and September, which are the most oppressive and exhausting of the whole year. The extreme rarefaction of the atmosphere now begins to operate as one of the causes tending to the production of those terrible hurricanes, or rushes of wind, called typhoons, which are justly dreaded by the inhabitants of the south of China; but which chiefly devastate the coasts of Hainân, and do not extend much to the north of Canton. The principal circumstances to be observed concerning these hurricanes are, the state of the barometer previous to and during the storm, the influence of the moon, and the localities in which they prevail. The barometer falls slowly for many hours, often a whole day before the commencement, the mercury sometimes descending nearly to 27 inches during the progress of the gale; while its rising is a sure sign of subsidence. Another sign of the approaching storm is the long and heavy swell which rolls in upon the sea-beech, without any apparent cause, for some time before the hurricane begins; but which may perhaps be explained by so much of the usual pressure of the atmosphere (equal to two inches, or a fifteenth part of the mercurial column) being removed from the surface of the water; a circumstance which may likewise partly account for the overwhelming seas which are so much dreaded by ships encountering the typhoons. In addition to the prognostics already noticed, the storms are preceded by a thick muddy appearance of the atmosphere, and a show of unusual disquiet among the sea-fowl. They seldom last forty-eight hours, and their duration is commonly confined to twenty-four, or less.

Natural History.—As regards the natural history of China, there is no subject on which Europe is less indebted to the Romish missionaries. The Jesuits, while employed in constructing their excellent map of the empire, which of course required that they should have free access to every part, lost an opportunity, which may perhaps never again occur, for investigating and describing its natural productions. The studies of zoology, botany, and mineralogy, it must however be observed, were then far short of their present state of advancement. We must here confine ourselves to a general statement of the most remarkable productions of China in the animal, vegetable, and mineral kingdoms, as they have been made known to us by later researches; observing, that in a country whose interior is so little accessible to Europeans, there must be a great deal that remains to be known and described. The animals, as well as vegetables of China, belong principally to the temperate zone; since the low average of the thermometer (which, as far south as Canton, is little above 70°), and the cold winters, are unfriendly to the existence of numerous tropical tribes which are found in corresponding latitudes of India. Animals being, for obvious reasons, more generally diffused over continents than plants, it follows that the number of cases in which the zoological productions of China have been found peculiar to that country are rare in comparison with the botanical ones. The larger and more ferocious descriptions of carnivorous quadrupeds are not common in a country so well peopled and cultivated. In the forests of Yunnân, to the south-west, the Bengal tiger is said to exist, and the animal is well known to the Chinese; but at Canton, so nearly in the latitude of Calcutta, it is quite a stranger. Lions are almost a fabulous animal with them. The woods of the south abound in a small but fierce description of wild cat, which is fattened in cages for the table. The domestic dog of China is uniformly one variety, about the size of a moderate spaniel, of a pale yellow and occasionally a black colour, and a coarse bristly hair on the back; sharp upright ears and peaked head, not unlike a fox's, with a tail curled over the rump. Bears are common in the hilly wooded parts of Chansy, west of Peking. Of the common ruminant animals, the Chinese possess several varieties of deer, particularly a spotted kind kept about their residences. Gerbillon describes a species of antelope abounding on the borders of Mongol Tartary, but called by the Chinese *huâng-yâng*, 'yellow goat.' The sheep of China are the large-tailed kind; and, as the people never use milk, cows are rare and of a peculiarly small kind. The buffalo used in ploughing is also very small, with a skin of slate colour, thinly covered with hairs. Dromedaries are much used as beasts of burthen between Peking and Tartary; but in China Proper the reasons which cause human labour to supplant every other have prevented their being adopted. Chinese horses are not numerous, and of a poor and stunted breed, being very ill fed and kept. Asses and mules are common in the north of the empire the mules are generally of a good size, and said to bear a higher price than horses, as being capable of more labour on less food. Of pachydermatous animals, the domestic pig of China is well known in England, and has been freely introduced into our farm-yards. The wild boar may be found in the half-reclaimed countries on the western borders, but not in Central China, nor on the east coast, where tillage and population have reached their present height. Of the other wild pachydermatous tribes, the elephant is not at present an inhabitant of China, unless it be in Yun-nân, nor is he used for purposes of either peace or war. The one-horned rhinoceros is found in the forests of the extreme west and south. Of rodent animals, the common rat attains to an unusual size, and is well known to be eaten by the lowest orders of the Chinese. Mr. Gray has described a glirine animal discovered by Mr. Reeves, being nearly allied to the bamboo rat of Sumatra, as a new genus, 'in teeth and general appearance; most nearly allied to *spalax*, from which it differs in its tail of moderate length, its exposed eyes and ears, and the more complex character of its molar teeth.'

The ornithology of China is distinguished by some splendid varieties of gallinaceous birds, as the gold and silver pheasants, to which has been lately added the *Reeves's pheasant*, the longest tail-feathers of which approach the extraordinary dimensions of six feet. Another description is called the *medallion* pheasant, from a beautiful membrane of resplendent feathers which is displayed or contracted according as the animal is affected. China abounds in wild fowl of all kinds, and particularly in immense flocks of geese, observable during winter near Canton. The *yuen-yang*, a teal of splendid plumage, has been called the 'mandarin duck,' and is remarkable for the attachment between the male and female. The fishing corvorant, employed on the shallow lakes of the country in capturing fish, has been described as a brown pelican with white throat; body whitish beneath, spotted with brown; tail rounded; irides blue, and bill yellow. Among the miscellaneous birds of China may be enumerated quails which are often trained to fight; the common ringdove, of which great numbers breed in the woods about Canton; and the peculiar crow of the country, marked with white about the neck.

---

* In the winter of 1835, a fall of snow occurred at Canton, two and a half inches in depth.

Of reptiles, it is remarkable that the largest kinds of saurians, as the crocodile and alligator, are unknown even as far south as Canton, probably in consequence of the vast population and traffic that exists on the rivers. Great numbers of the small lizard tribes are visible during the hot months, some of them infesting trees and shrubs, while others inhabit holes in rocks or old walls. Several freshwater tortoises have been lately sent home, and two new genera of batrachians, or the frog kind, are described by Mr. Gray. Notwithstanding its situation under the tropic, Canton is little infested by the venomous kinds of serpents; the species most dreaded is a smallish slender snake, between two and three feet in length, called by the Chinese 'the black and white,' from being surrounded from head to tail with alternate rings of those colours.

Of fishes, a large collection of Chinese specimens has been lodged by Mr. Reeves in the British Museum. The golden carp is one of the most distinguished kinds, and has long been bred in Europe from the original specimens which were carried by the Dutch first to Java and thence to Holland. Of edible sea fish, the best kinds near Canton are a sort of rock-cod, and a flat fish called *Tsâng-yu* by the Chinese, and 'pomfret' by Europeans. Soles are good and plentiful, but the fish most valued by native epicures is the sturgeon.

Among insects, the locust commits great ravages occasionally in particular districts, and rewards are given for its destruction. Some of the most poisonous tribes, as scorpions, are not met with at Canton; but the centipede, which the Chinese call by exactly the same name of pĕ-tso, 'hundred feet,' is common. A monstrous spider has been seen, inhabiting trees, and attaining to a size and strength that enable it to devour small birds entangled in its webs. Dr. Abel notices the *Scarabæus molossus*, the *Cerambyx farinosus*, and the mole-cricket of a large size. At a mountain lying eastward of Canton, called Lo-fow-shan, there are butterflies of a gigantic size and very brilliant colours, a selection of which are sent annually to Peking. The pĕ-lă-shoo, or wax-tree, affords nourishment to an insect which is supposed to belong to the Coccus tribe, but which has never yet been correctly ascertained.

At the head of Chinese botany may properly be placed the tea-plant. The specimens from the black and green tea countries differ slightly in the leaf, the latter being a thinner leaf, rather lighter in colour, and longer in shape, than the other; though the Chinese themselves acknowledge that either black or green tea may be prepared from any tea-plant. The *Camellia* bears the same name in China with the tea-shrub, and possesses most of its botanical characters; they in fact constitute two genera very closely allied. The *Laurus camphora*, one of the most remarkable productions of China as well as Japan, is a fine timber-tree, growing in the southern provinces to the height of fifty feet. From the seeds of the *Dryandra cordata* the Chinese extract a varnish for boats, and for the coarser implements of domestic use. The fine japan varnish, however, is obtained from the *Tsiĕ-shoo*, or lacker-shrubs, a species of *Rhus*, from which the varnish distils like gum. The Chinese procure their tallow from the *Croton sebiferum*, the seed of which, as soon as it is ripe, opens and divides into three parts, discovering as many kernels within the capsule, each attached by a separate foot-stalk, and covered with the vegetable grease of a snowy whiteness. The plant from which the pithy substance vulgarly called 'rice-paper' is prepared, seems to be a leguminous species growing in marshes, and found in some parts of India. The square pieces purchased in China are obtained from the stem, which, not being above an inch or two in diameter, is cut in a circular manner, and the cylinder in this manner rolled out and flattened. The *Smilax*, or China root of commerce, commonly known as a sudorific, may be seen growing near Canton. That valuable medicine rhubarb is cultivated to the northward, in the cold and mountainous province of Shensy. The Chinese cassia, an inferior cinnamon, is grown in Kuâng-sy, and largely exported in European ships.

Among the most remarkable fruits of China are three distinct species of orange, as different as one sort of fruit can be from another of the same genus. The first is the 'China orange' of Europe; the second is of a pale yellow colour, but very sweet, and with a highly aromatic rind; the third, and perhaps best sort, has a deep crimson rind when ripe, quite detached from the fruit, the lobes of which are almost loose, and surrounded with a kind of net-work of fibres. Another description of *citrus*, of the lemon kind, by the exercise of some horticultural ingenuity, is made to run entirely into rind, the whole terminating at the head in long narrow processes like fingers, whence it has obtained the appellation of Fŏ-show, 'the hand of Fŏ.' Among the peculiar fruits of China, the *Lichi* has been naturalized in Bengal. Another of the Dimocarpus sort, called *Loong-yen*, or 'dragon's eye,' is much smaller, and has a smoother skin. The *Loquat* is a fine fruit (when well ripened) of the *Mespilus* kind. The *Wampee*, as it is called at Canton, has been compared to the gooseberry, which it resembles only in size; its fruit, which grows in bunches on a good sized tree, has a yellow skin, inclosing a rather acid pulp that surrounds two or three seeds of a green colour. At the head of cultivated flowers the Chinese place the *Nelumbium*, in consideration of both its beauty and utility. The seeds, in form and size like an acorn without its cup, resemble nuts in flavour: the roots are sliced and eaten as fruit. Another highly esteemed flower is the *Olea fragrans*, allied to the olive of Europe, and remarkable for the fine scent of its blossoms. The famous *Mow-tân*, or Tree-peony, flourishes only in the north of the empire. A flower much cultivated is the *Chrysanthemum Indicum*, valued for the variety and richness of its colours, and now common in this country. The *Choo-lân* (Chloranthus inconspicuus) is used in scenting the tea that bears its name.

The variety of surface through the wide extent of the empire affords a rich fund of minerals and metals. There can exist no doubt of the abundant supply of coal throughout China, nor of its general use, which we find from Marco Polo was known to them before its adoption in Europe. Lime they possess in all its combinations. The dark [illegible] marble used at Canton is coarse, and unsusceptible of a fine polish; the shops contain large quantities of striated gypsum or alabaster. At the head of minerals the Chinese place their famous *yu* stone, which is nephrite, or jade. As the country abounds in the primitive rocks, it is consequently rich in metals. Gold is obtained in the native state from the sands of the rivers in Yun-nân, near the frontiers of the Burmese country, well known for its richness in that metal; in Yun-nân also silver mines are worked. Ordinary copper comes from Yun-nân and Kuei-chow, and an abundance of malachite, or green copper-ore, is obtained near the great lake in Hoo-kuâng. The famous pĕ-tung, or white copper, which takes a polish not unlike silver, comes from Yun-nân: a considerable quantity of quicksilver is obtained in Kuei-chow; and there is a rich mine of tutenague or zinc in Hoo-pĕ.

Government.—The government of China is in principle an absolute despotism, and the succession depends on the will and nomination of the reigning emperor. The authority of a father over his family is well known to be the exemplar or type of political rule in the country. It is the object of the first of the 'Four Books' of Confucius to inculcate that from the knowledge and government of oneself must proceed the proper economy and government of a family, and from the government of a family, that of a province, and of a kingdom. The emperor is called the father of the empire; the viceroy of the province over which he presides; and the mandarin, or magistrate, of the which he governs; and the father of every family is absolute ruler of his own household. 'There is nothing more remarkable,' observes Mr. Davis, 'in their ritual, and in their criminal code, than the exact parallel which is studiously kept up between the relation in which every person stands to his own parent, and to the emperor. For similar offences against both he suffers similar punishments; and at the death of both he mourns the same time, and goes the same period unshaven; and both possess nearly the same power over his person. Thus he is bred up to civil obedience *tenero ab ungui*, with every chance of proving a quiet subject at least. Such institutions certainly do not denote the existence of much liberty; but if peaceful obedience and universal order be the sole objects in view, they argue on the part of the governors some knowledge of human nature, and an adaptation of the means to the end.' The emperor is head of the state religion, and, as high-priest of the empire, can alone, with his immediate representatives, sacrifice in the government temples. No hierarchy is maintained at the public expense, nor any priesthood attached to the Confucian or state religion, as the sovereign and his great officers perform that part. The two separate religious orders of Fo (Budha) and Taou, which are only tolerated, and not maintained, by the government, derive support entirely from their own funds, or from voluntary private contributions.

With respect to the machinery of civil government, the emperor's principal ministers form the 'interior council-chamber,' and the chief councillors are four in number, two Tartars and two Chinese; the former always taking precedence. Below these are a number of assessors, who form the chief council of state. The body whence these chief ministers are generally selected, is the Hân-lin, a sort of imperial college, or National Institute. The details of government business are distributed among six boards or tribunals, viz., 1. The board of civil appointment, which takes cognizance of the conduct and administration of all civil officers; 2. The board of revenues, which regulates all fiscal matters; 3. The board of rites and ceremonies; 4. The military board; 5. The supreme tribunal of criminal jurisdiction; 6. The board of public works. A very peculiar feature of the government is observable in the Too-chă-yuen, or office of censors, the members of which are generally styled Yushe. There are two presidents, a Tartar and a Chinese, and the members consist in all, of about forty or fifty, several of whom are sent to various parts of the empire, as imperial inspectors, or perhaps, more properly speaking, spies. By the antient custom of the empire, they are privileged to present any remonstrance to the sovereign without danger of losing their lives; but they are frequently degraded if their advice is unwelcome. The provinces are placed under the principal charge, either, singly, of a Foo-yuen, or governor, or two provinces together are made subject to a Tsoong-to, or general governor, who has a Foo-yuen under him for each single province. Canton and its adjoining province are together subject to the Tsoong-to, commonly called by Europeans the Viceroy. In each separate province there is a chief criminal judge and a treasurer, the latter having usually cognizance of civil suits, but his special business is the charge of the territorial revenue. With this, he first of all defrays the civil and military expenses of his province, and whatever surplus remains is remitted by him to Peking, in silver or in produce. The total surplus of all the provinces remitted to the capital is about 11 or 12 millions sterling annually, which has very erroneously been taken for the whole revenue of the empire. The subordinate cities and districts of each province in the three ranks of Foo, Chow, and Hien, are under the charge of their respective magistrates, who take their rank and titles from the cities they govern. The total number of civil magistrates through China is estimated at 14,000. At Canton the amount and importance of the European trade has given rise to the special appointment of the Haekuân, or commissioner of customs, called by Europeans Hoppo, who ranks as third in the province, but has no territorial jurisdiction beyond the trade. No individual in China can hold a magistracy in his own province; and each public officer is changed about once in three years, to prevent growing connexions with those under his government. A son, a brother, or any other very near relation, cannot hold office under a corresponding relative. The various degrees of civil and military offices are partly distinguished by the colour of the ball which they wear at the apex or point of their conical caps. These are red, light blue, dark blue, crystal, white-stone, and gilt. Each ball is accompanied by its corresponding badge, which is a piece of silk embroidery, about a foot square, with the representation of a bird, or other device, on the breast and back of the ceremonial habit; together with a collar or necklace of very large beads, down to the waist.

The whole amount of military throughout the empire including the militia of each district, has been estimated at 700,000, of which the largest portion are fixed to their native districts, and cultivate the land, or follow some other pursuit. The whole are under the direction of the military tribunal, or board, at Peking. The trusty Tartar troops are ranged under the eight standards, each of them comprising 10,000 men, and making a total of 80,000 for a standing army. Very few mounted soldiers were seen by either of our embassies, and whatever may be their actual amount, they are said to be nearly all Tartars. A great difference seems to exist between the pay of Tartars and Chinese. One of the former, being a foot-soldier, receives about five-pence a day, with an allowance of rice; one of the latter, only four-pence, without the rice. The principal arms of the cavalry are bows and arrows, the bow being of elastic wood and horn combined, with a string of silk. Their swords are generally ill made, and their matchlocks are considered by them as inferior weapons to the bow and arrow. Some are provided with shields, composed of rattans turned spirally round a centre.

The residence of the emperor and his court for some hundreds years past has been removed from Nanking to Peking, a city whose population has been stated at double that of London; but various reasons conduce to render this altogether improbable. Notwithstanding the great extent of the area enclosed within the walls, there are so many open spaces of great extent, that it is difficult, taking the lowness of the one-storied buildings into consideration, to imagine how such an immense number can exist within its precincts. A large portion of the Northern or Tartarian city is occupied by the enclosure which contains the palace and pleasure grounds of the emperor; the remainder is studded over at intervals with official or religious buildings, all of them surrounded by large open courts; and the Chinese city to the south has some very extensive spaces occupied by immensely-spreading public buildings, with grounds attached. There are, besides, large sheets of water, and gardens devoted to the growth of vegetables for the city. The streets of Canton and of most of the cities are extremely narrow, admitting only three or four foot passengers abreast; but the principal thoroughfares of Peking, connecting its different gates, are fully one hundred feet in width. These are unpaved, probably in consequence of the difficulty and expense of procuring stone in the flat that surrounds the city. In rainy weather the principal ways are said to be in a dreadful state, from the want of proper drains, and in consequence of the perfect level of the ground not allowing the water to run off.

Population.—The population of the empire has naturally been a subject of investigation with those persons who had the best opportunities of pushing the inquiry with success. A number of natural, social, and political causes no doubt combine to explain the very dense population which the country unquestionably contains. The advantages which China possesses from nature have been improved to the utmost by its industrious inhabitants: agriculture, the source of food, has been honoured and encouraged beyond every other species of industry. There is no meadow cultivation whatever; nothing is raised by labour for the food of cattle, but all for man, since the very small number of horses, oxen, or sheep maintain themselves as they can on pastures unsusceptible of cultivation; and in no other country is so much food derived from the waters. The political causes which tend to swell the population of China are numerous and powerful. Among these are the paternal rights, which continue during life, and render a son, even in that over-peopled country, an important acquisition. The laws of the empire grant life sometimes even to a condemned homicide, if the want of another son or grandson render his existence necessary to the support of a parent. The other cause, which renders male children so desirable, is the sentiment regarding sacrifices at the tombs and in the temples of ancestors. In default of male children there is a legalized mode of adoption by which the line is perpetuated and the family prevented from becoming extinct. Even the tendency of slavery to check population is counteracted by a law which makes the owners of domestic slaves, who do not procure husbands for their females, liable to prosecution; but the perpetuation of families does not tend more to the density of the population than the manner in which those families live and are maintained. It is a universal system of clubbing on the most economical plan, and the claims of kindred being universally admitted and enforced, the property of families is made to maintain the greatest number possible. Another political cause is the obstacle that exists, both in law and prejudice, to emigration. Besides the statute in the penal code, which punishes this offence according 'to the law against communicating with rebels and enemies,' the abandonment of his native place, and of the tombs of his ancestors, is always abhorrent to the mind of a Chinese. To the above list of causes tending to produce the excessive population of China, must be added the uninterrupted peace which has been enjoyed by that country since the complete establishment of the Manchow dynasty, a period now considerably exceeding a century.

Under the circumstances above briefly enumerated, there is less difficulty in admitting the extraordinary amount of population which has been given from various authorities, involving, however, statements occasionally so contradictory that it seems not altogether easy to come to any satisfactory result as to the actual number. Grosier made the population in 1743 amount to 198 or 200 millions. There is nothing incredible in this, considering that the area of China Proper is eleven times that of the British Islands. But on comparing it with the 333 millions of Lord Macartney's authority, just fifty years afterwards, an increase of considerably more than half within that period seems very large. When the census was taken by Kien-loong, a little before Lord Macartney's embassy, that emperor issued a proclamation addressed to the whole of his subjects, calling on all ranks and conditions of men to economize the gifts of heaven, and by industry to increase the quantity; for, observing the increase of population since the period of the conquest, he looks forward with deep concern to the future, when the numbers of the people shall have exceeded the means of subsistence. According to this highest authority then, a very great increase had really taken place; but when we come to the particulars, they seem to stagger all belief. The emperor goes on to say, that in the 49th year of Kâng-hy, the second sovereign of his family (and under the old system of the poll-tax), the population of the empire was rated at about 23,312,000; and that by the late census, according to returns from all the provinces, it amounted to 307,467,200. Unless some way can be found of reconciling such an account with bare possibility, it seems unworthy of serious acceptance. But we must remember that a great portion of the country was actually *unsubdued* in the reign of Kâng-hy. The southern parts of the empire held out obstinately against the Tartars, and some of them were long governed by independent Chinese rulers. These then for the time must have been excluded from a census of the subjects of the Manchow dynasty. Again we must call to mind that the census so remarkable for its small amount under Kâng-hy was with reference to a poll-tax, and to military service, two objects which were of all others the least calculated, during an unsettled and half-subdued state of the country, to ensure a correct or full return. The Manchow conquest is said, by the combined effects of war and flight, to have reduced the population of China to less than half its amount under the Ming race; but the conquest has since been followed by almost unexampled peace and prosperity during a period considerably exceeding a century. A census, said, on the authority of a Chinese statistical work, to have been taken in 1812, goes beyond the amount given to Lord Macartney, and makes the population reach the number of 360,279,897. Our faith in this must of course be determined by the degree of credit to be attached to the Chinese census. The account is said to be made up from the returns received in detail from every village in the empire, in which the houses are provided with what is called a *mun-pae*, or 'door-tables,' on which are inscribed all the individuals of a family. The lists are transmitted through several channels before they reach Peking, and may therefore occasionally, if not always, be liable to falsification by those who wish to flatter the emperor with the idea of increase. Taking the area of China at 1,200,000 square miles, in round numbers, we should have the latest estimate, 300 inhabitants on a square mile, which is more than England or Holland possesses.

Revenues.—The revenues of China are derived principally from a land-tax, and the monopoly of salt, to which are to be added something for customs and transit-duties. At the Manchow conquest a capitation or poll-tax was imposed, but this was soon taken off again; and the second emperor of the dynasty ordained that the land-tax, which under the Chinese had been taken from the cultivators, should ever after be taken from the land-owners. The subject of the Chinese revenues seems never before to have been very clearly understood. From the produce of taxation in each province, the treasurer of that province deducts the civil and military expenses, and all outlays, whether for public works or otherwise, remitting the surplus to Peking either in money or kind. This surplus has been the only point clearly ascertained, and it has been very erroneously mistaken for the gross amount of the revenue. The difficulty of ascertaining the real expense that attends the administration of the empire arises from a considerable portion of the taxes being levied in commodities instead of money, as grain, salt, silks, and stores of different sorts. A portion of the allowances of public servants, especially at Peking, as well as of the stipends of imperial relatives, is paid in the shape of rations and supplies. Du Halde states the total revenue of the empire, including the provinces, at 'about 200 millions of taels (or upwards of 60 millions sterling), of which only 12 millions sterling are transmitted to Peking.' The accuracy of the latter amount seems pretty nearly confirmed by what appeared in a Peking gazette of 1833. A Tartar officer therein states, 'that the whole receipts at Peking do not exceed 40 millions of taels, which is 12 or 13 millions sterling:' again, it appears from a statement translated by Dr. Morrison, that the surplus from land-tax, transmitted to Peking by two provinces, was 5 millions of taels, which, taken as an average for eighteen provinces, would give 45 millions; but one or two of them supply much below that average, and the true total may therefore be 40 millions, as above.

Laws.—We possess a translation of the Tartar-Chinese penal code, from Sir George Staunton, and of this specimen of legislation a very advantageous comparison with other Asiatic systems has been made by an able critic in the 'Edinburgh Review.' 'When (says he) we turn from the ravings of the Zendavesta, or the Puranas, to the tone of sense and of business of this Chinese collection, we seem to be passing from darkness to light; from the drivellings of dotage to the exercise of an improved understanding; and redundant and minute as these laws are, in many particulars, we scarcely know any European code that is at once so copious and so consistent, or that is nearly so free from intricacy, bigotry, and fiction. In everything relating to political freedom or individual independence, it is, indeed, wofully defective; but for the repression of disorder, and the gentle coercion of a vast population, it appears to us to be, in general, equally mild and efficacious.' If we estimate Chinese legislation by its result, we shall find it (as Sir George Staunton observes) wholly inconsistent with the hypothesis of a very bad government, or a very vicious state of society. Mr. Ellis, who had long been in Persia and India, pronounced China 'superior to the other countries of Asia, both in the art of government and the general aspect of society;' and adds, 'that the laws are more generally known, and more equally administered; that those examples of oppression, accompanied with infliction of barbarous punishment, which offend the eye and distress the feelings of the most hurried traveller in other Asiatic countries, are scarcely to be met with in China; that the proportion which the middling orders bear to the other classes of the community appeared to be considerable; that, compared with Turkey, Persia, and other parts of India, an impression was produced highly favourable to the comparative situation of the lower orders.' It is a popular maxim with the Chinese, that to violate the law is the same crime in the emperor as in a subject. 'This plainly intimates (observes Mr. Davis) that there are certain sanctions which the people in general look upon as superior to the will of the sovereign himself: these are contained in their sacred books, whose principle is literally, *salus populi suprema lex*; and however much this principle may at times be violated under the pressure of a foreign Tartar dominion, it nevertheless continues to be recognised, and must doubtless exercise more or less influence on the conduct of the government.'

Moral Character, &c.—The moral character of the Chinese people is a compound of bad and good traits, which, as usual, may be traced to the influence of their political and social system. The late Dr. Morrison seems to have formed a fair estimate of a nation with whom he was better acquainted than most Europeans. 'In China (he observes) there is much to blame, but something to learn; and moral instruction is ranked above physical.' The consequence is, that industry, tranquillity, and content, are unusually prevalent in the bulk of the population. Notwithstanding his power is absolute, the emperor himself always endeavours to prove that his conduct is based in reason and benevolence, the truth of the argument being, of course, a distinct affair. From the habits in which they are brought up, the people are more ready to reason with each other than to resort to violence. The advantageous features of their character, as mildness, docility, industry, peaceableness, subordination, and respect for the aged, are accompanied by the vices of insincerity and falsehood, with their consequences, mutual distrust and jealousy. Lying and deceit, being generally the refuge of the weak and timid, have always been held among us as disgraceful vices, while the Chinese, at any time, do not attach the same degree of disgrace to deceit, and least of all when it is practised towards a European. It would however be as unreasonable to infer the character of the whole nation from the unfavourable aspect in which it appears at Canton, a trading seaport, as to form an estimate of our national character in England from an experience equally limited and disadvantageous. It has, in fact, been considered as a matter for surprise, that the Chinese at Canton should be no worse than we find them: they are well acquainted with the maxim of their government, by which it professes 'to rule barbarians like beasts, and not like native subjects;' and they are continually supplied by the local authorities with every motive to behave towards strangers as if they were a degraded order of beings. Their conduct to Europeans therefore is different from their conduct among themselves.

In their physical characteristics, the Chinese have been recognised as superior to many other Asiatics. A finer shaped and more powerful race of men exist nowhere than the coolies or porters of Canton; and as sailors, they have been found stronger and more efficient than natives of India on board of English ships, but it has always been both difficult and expensive to employ them. Though the Chinese are allied to the Mongols in the general cast of their features, the harsher points of the latter are softened down in the former considerably: in the thickness of the lips, the Chinese in some degree approaches, but by no means equals, the Negro, nor is that feature at all so prominent as in the latter; the nose is flattened, and the nostril expanded in the Chinese, but not to the same extent as in the African: there is the same lank, black, and shining hair in the case of the Chinese as in that of the North American Indians; the same obliquity of the eyes and eyebrows, turned upwards at the outer extremities, and a corresponding thinness and tufty growth of beard. The Chinese too is distinguished by a nearly total absence of hair from the surface of the body. In the smallness of the hands and feet, and of the bones of the body, compared with Europeans, he resembles the generality of Asiatics. The features of the people in the South have perhaps less of the harsh angularity of the Tartar countenance than at Peking. Among those who are not exposed to the climate the complexion is fully as fair as that of the Portuguese; but the sun has a powerful effect on their skins, and that upper portion of a man's person which is habitually exposed in the summer above his loose trowsers is often so different from the remainder, that when stripped he looks like the lower half of a European joined on to the upper moiety of an Asiatic. Up to the age of twenty, or a little more, they are often very good looking; but soon after that time the prominent cheek-bones generally give a harshness to the features as the roundness of youth wears off. With the progress of age the old men in most cases become very ugly, and the old women, if possible, still more so.

China is now politically divided into provinces, of which seven extend entirely or partly over the great plain, two comprehend the hilly districts, two others the mountainous country along the sea, and the others the mountainous country in the interior.

1. Pe-tche-li extends over the most northern and less fertile portion of the plain, but is well cultivated, and produces, besides vegetables for the supply of the capital, large quantities of millet and wheat. In it is situated Peking, the capital of the whole empire; the capital of the province is Pao-ting-foo, a very large and populous town in which the governor resides.

2. Chang-tung comprehends a part of the plain and the peninsula of Chang-tung, on which an isolated mountain-range rises to a moderate height. It produces wheat, millet, and cotton. Its capital is Tsi-nan-foo, a large and populous town. Lin-tchin-tcheou, at the confluence of the canal with the river Eu-ho, is the deposit of goods which are carried from the southern provinces to Peking, and a very large place.

3. Kiang-su, which with the following province once formed that of Kiang-nan, comprehends the low and swampy country on both sides of the Great Canal. It chiefly produces rice and pulse, and has extensive fisheries. Besides the capital, Nanking, it contains many large towns on the banks of the canal, among which the most remarkable are Yang-tcheou-foo, which is at a short distance from the Yang-tse-kiang, and carries on an active trade; and Su-tcheou-foo, which to an extensive commerce unites great industry in manufacturing silk and cotton goods. Its principal port is Shang-hae.

4. Ngan-hoei or An-hoi, on both sides of the Yang-tse-kiang, produces, besides grain and rice, some silk. In its south-eastern districts are extensive plantations of tea, and also some mines of gold, silver, and copper. The capital is Ngan-king-foo, on the Yang-tse-kiang.

5. Ho-nan is chiefly in the plain, but its western districts are traversed by the Pe-ling mountain-range and its branches. It is rich in grain and cotton, and is supposed to contain some mines. In its south-eastern districts tea is cultivated. The capital, Khai-fong-foo, is not far from the banks of the Hoang-ho; but the most populous town appears to be Ho-nan-foo, on a river which falls into the Hoang-ho, in a richly-cultivated valley.

6. Hoo-pĕ comprehends part of the undulating portion of the plain, and the wide valleys of the Han-kiang and Yang-tse-kiang, with some mountainous districts. It lies in the centre of China, and formerly constituted, with the more southern province of Hoo-nan, one province called Hou-quang. Its fertility is very great: its products are grain, cotton, silk, and tea, which are cultivated on its north-eastern border. Its capital, Wu-tchang-foo, situated on the Yang-tse-kiang, opposite its junction with the Han-kiang, is one of the largest of the inland towns of China, and carries on an extensive commerce. King-tcheou-foo, farther to the west, likewise on the banks of the Yang-tse-kiang, has also a very extensive trade.

7. Che-kiang comprehends the south-eastern corner of the plain, and the northern portion of the mountainous country extending along the sea. It produces more green tea than other provinces, and also silk, rice, grain and pulse, in abundance. Its capital is Hang-tcheou-foo, on the banks of the Tsien-tong-kiang, at the southern termination of the Great Canal, in a very pleasant situation. According to Staunton, its population was thought to be not much less than that of Peking, and the missionaries estimated it at one million. None of the houses exceed two stories in height: the streets are well paved. It has extensive manufactures of silk and cotton goods, especially in flowered and embroidered satins, and a very active commerce, as well by means of the canal as by the river, which is navigable for large vessels up to the town. The principal port of this province is Ning-po.

8. Kiang-si extends over the eastern portion of the hilly country, along the western side of the Nan-ling range, and produces in its well-cultivated valleys and plain, grain, rice, silk, cotton, indigo, and sugar. It has some plantations of tea. The capital, Nan-tchang-foo, on the Kan-kiang, not far from the place where it falls into the lake Poyang, is a large town, and carries on a great trade. In the hilly country which begins at some distance from the lake of Poyang on the east, is the borough of King-te-ching, which is said to contain one million of inhabitants, who are occupied exclusively in the fabrication of china-ware, which is here made in the greatest perfection. The number of furnaces is said to amount to five hundred. Kan-tcheou-foo, on the Kan-kiang, not far from its source and the Mei-ling Pass, is a large town, in which Indian ink and varnish are made on an extensive scale.

9. Hoo-nan, or the southern part of the antient province of Hoo-quang, contains the remainder of the hilly country. Its productions are like those of Kiang-si. It is said to be rich in minerals. The capital, Tchang-cha-foo, on the Heng-kiang, is a large commercial town. Yo-tcheou-foo, on the channel connecting the large lake of Tung-ting with the Yang-tse-kiang, also carries on a very active trade.

10. Fo-kian, or Fochan, extends over the mountainous country on the shores of the sea opposite the island of Formosa. Some of the summits of the Nan-ling range here rise to a great height, but do not attain the perpetual snow-line. The higher parts of some of the mountain-ridges are bare; others are covered with trees, but in its extensive and fine valleys all the commercial productions of China are met with, except perhaps varnish. Its plantations of tea are extensive, and the greatest quantity of black tea is grown here. The inhabitants of this province are noted for their industry, and still more for their spirit of enterprise and their love of emigration. The numerous settlements of Chinese in the islands of India and the countries without the Ganges have been formed by them, and are continually increasing by new adventurers from Fo-kian. The capital is Fu-tcheou-foo, on the river Mingho, over which a bridge is built of thirty-three arches of fine white stone. The largest Chinese vessels can come up almost to the wall of the city, the maritime commerce of which is very considerable, and its population greater than that of Canton. Tsuen-tcheou-foo, between Fu-cheou-foo and Amoy, is likewise a large town. A great number of vessels sail hence to the neighbouring countries. It has a bridge built over an arm of the sea, on 300 piers of black stone. Here is also the harbour of Amoy, which was formerly visited by Europeans. [AMOY.]

11. Quang-tun, or Canton, extends over the whole southern coast from 117° E. long. to the very boundary of Cochin-China, and is likewise mountainous, but its mountains are not so high as those in Fo-kian. It has a great number of fine and wide valleys, and the plain about Canton is of considerable extent: it produces all the commercial commodities of China, except tea and varnish. The number of its harbours is considerable, but Canton is alone visited by Europeans. This town is the capital of the province. [CANTON.] Fochan, lying south-west of Canton, at a distance of about 20 miles, is said to contain a population of one million of souls, and to have numerous manufactures of silk, cotton, china-ware, and colours.

12. Quang-si, extending on both sides of the Ta-si-kiang, is covered with mountains: the valleys, which are generally narrow, occupy a small portion of its surface. The mountains belonging to the Nan-ling range, enclosing the northern side of the province, rise to a great height, and some summits above the perpetual snow-line. The forests on the declivities of the hills are extensive. Its productions are rice, silk, and timber, and it is supposed to contain gold and other metals. A mountainous district, towards the northern boundary of this province, is inhabited by the Tchang-Colas, an aboriginal and independent tribe, differing from the Chinese in language and manners. The capital of the province, Kuei-ling-foo, lies in a narrow but fine valley.

13. Kuei-tcheow, to the north of Quang-si, is one of the most mountainous provinces of China, being traversed in all its length by the highest portion of the Nan-ling range, several summits of which are always covered with snow. In these mountains live the Seng Miao-tsee, an aboriginal tribe, who differ in language and manners from the Chinese, and often make war on them. Many fortresses have been erected in the narrow parts of the valleys to stop their incursions. Its productions are timber and metals, gold, silver, &c., but especially copper and quicksilver. The capital is Kuei-yang-foo, a comparatively small town, its circuit being not much more than two miles.

14. Yun-nan, the most south-western province, bordering on Cochin-China, Siam, and the Birman empire, forms an extensive but uneven table-land, studded here and there with high mountains, especially towards the north, where there are several snow-capped summits. The mountains towards the south, on the boundary line of the Birman empire and Siam, are inhabited by a tribe of mountaineers, called Lolos, or Lowas, who are only nominally dependent on the Chinese. Its commercial wealth consists of the produce of its mines, gold, silver, copper, &c., and of its forests, which contain timber trees, and several kinds of rare wood. The capital, Yun-nan-foo, situated on the least mountainous part of the table-land, is a considerable place, and carries on an active trade with the Birman empire. A much-frequented road, running mostly on the banks of the Yang-tse-kiang, connects this town with the interior provinces of China, and another passes hence, west to Yang-tchang-foo, another considerable town, perhaps larger than Yun-nan. From this place the road continues to the Irawaddi river, and to Bhanmo, in the Birman empire. A considerable trade is carried on by this route. [BIRMAN EMPIRE.]

15. Se-tchu-an, the largest of the provinces, is nearly everywhere enclosed by high mountain-chains, and its interior is traversed by lower ranges. Its valleys are commonly wide, and often expand into plains. The soil is rich, and produces every kind of grain, as well as rice and sugar, in abundance; but its commercial riches consist principally of silk, timber, and different kinds of metals. Its capital, Tching-too-foo, situated on an island formed by the Min-kiang, in an extensive and richly-cultivated plain, is a place of considerable trade, and very populous. Koci-tcheou-foo, on the banks of the Yang-tse-kiang, is one of the most commercial places in the interior of China, and very populous.

16. Shen-si is more covered with rugged mountains than Se-tchu-an, and contains a much smaller portion of cultivable land; yet the wide valleys through which the Wei-ho and Han-hiang run are very fertile, and produce abundance of wheat, millet, and pulse, but little rice. The capital is Si-ngan-foo, on the Wei-ho, once the metropolis of the whole empire, a town so large that it is compared with Peking itself; it is strongly fortified, and carries on a considerable trade.

17. Shan-si is still more mountainous than Shen-si; it has one wide and fertile valley along the banks of the Fen-ho, or Fien-ho, which is well cultivated, and studded with villages and towns. It exports wheat, millet, raisins, iron, and coal. The capital is Tai-yuen-foo, a large place, with considerable manufactures in silk and carpets, and some trade. Tai-tong-foo is one of the principal fortified places near the Great Wall.

18. Kan-si, the most north-western province of China, consists of the western portion of Chen-si, to which has been added a comparatively narrow tract of land, which extends far westward to the centre of Asia. This tract has been added with the view of separating the warlike and wandering tribes, which inhabit the table-lands to the north and west of China, from one another, and of preventing their incursions into China. The eastern part of this province is studded with high and many snow-capped mountains, and the western extends over the stony and sandy deserts of Central Asia; the whole is a poor country, and thinly inhabited. The capital is Lan-tcheou, a small place, on the banks of the Hoang-ho, which however carries on a brisk trade with the tribes inhabiting the table-lands to the north and west of it.

To these eighteen provinces may be added the province of Leao-tong, or Mougden, which extends along the northern shores of the Hoango-Hai, or Yellow Sea. It constituted formerly a part of Manchuria, but after the present dynasty had ascended the throne of China, this portion was separated from it, and considered as the domain of the imperial family. It is divided from China by the eastern extremity of the Great Wall, and from Mongolia by a stockade of wooden piles, which extends to the mountains which separate it from Corea. This country is covered with high mountains, except on the banks of the Leao-ho, where there is a plain of considerable extent, and pretty well cultivated. Here is the capital, Mukden, or Mougden, now called Fung-thian-foo, a place of moderate extent, in which are the tombs of the Manchow dynasty. Towards the boundary of Corea is Fon-Hoan, traversed by the only road which connects Corea with China, and on which some trade is carried on.

History.—Without attempting to deny to the historical records of the Chinese empire a very high degree of antiquity it is now pretty generally admitted, on the testimony of the most respectable native historians, that this point has been considerably exaggerated. In reference to the earliest traditions of their history, a native commentator observes, 'it is impossible to give entire credit to the account of these remote ages.' The persons styled Fohy, Shin-noong, and their immediate successors, must be ranged rather under the head of mythology than of history; resembling those demi-gods and heroes of Grecian fable who rescued mankind from primeval barbarism. The fabulous part of Chinese history commences with Puăn-koo, who is represented in a dress of leaves, and concerning whom everything is wild and obscure. He is said to have been followed by a number of persons with fanciful names, who, in the style of the Hindoo chronology, reigned for thousands of years, until the appearance of Fohy, who is said to have invented the arts of music and numbers, and taught his subjects to live in a civilized state. At length came Yaou and Shun, who are stated to have been the patterns of all Chinese emperors. To the age of Shun they refer their tradition of an extensive flooding of the lands, which by some has been identified with the Mosaic deluge. It was for his merit in draining the country, or drawing off the waters of the great inundation, in which he was employed eight years, that 'Yu the Great' was chosen by Shun for his successor. He commenced the period called Hea, upwards of 2100 years before Christ; and the whole of the long space of time included under Hea and Shang is full of the marvellous: until Woo-wong was called upon to depose a tyrannical emperor, the last of the Shang, about 1100 years B.C. With him began the period of Chow, which may be considered as the commencement of authentic history, and during which Confucius himself lived. Though it might be going too far to condemn all that precedes that period as absolutely fabulous, it is still so much mixed up with fable as hardly to deserve the name of history. The race of Chow filled the long period of 800 years, during which China appears to have been divided into a number of petty independent states, engaged in perpetual disputes with each other. The king of Tsin had long been growing powerful at the expense of the other states: he fought against six nations, and at length compelled them all to acknowledge his authority. The chief government began now to assume the aspect of an empire, which comprehended that half of modern China lying to the north of the great river Kiang, but which was doomed, after the lapse of some centuries, to be split again into several parts. The first emperor of the Tsin dynasty rendered himself famous by the erection of the Great Wall, which has now stood for 2000 years; as well as by ordering all the books of the learned (including the writings of Confucius), to be cast into the flames. About the year 201 B.C., the race of Tsin was succeeded by that of Hân, which filled one of the most celebrated periods of Chinese history. It was now that the Tartars became the cause of endless disquiet to their more civilized and peaceful neighbours, who were frequently obliged to buy them off with tribute. The period of the Jan-kuo, or 'Three States,' into which the country was divided towards the close of Hân, about A.D. 184, is a favourite subject of the historical plays and romances of the Chinese. The leader of one of these 'Three States,' having at length obtained the sovereignty, established the capital in his own country Honân, and commenced a new dynasty. In consequence of the distractions which had arisen from women and eunuchs interfering in affairs of government during the period of the 'Three States,' a kind of salic law was passed, that 'queens should not reign, nor assist in public matters,' and accordingly we meet with no female sovereigns in their history. On the conclusion of this race of monarchs, in A.D. 416, China became divided into two principal kingdoms, Nanking being the capital of the southern one, and Honân of the northern. For about 200 years afterwards, five successive races (Woo-tae) rapidly followed each other, and the salutary rule of hereditary succession being constantly violated by the strongest, the whole history of the interval is a mere record of contests and crimes. At length, in A.D. 585, the north and south of modern China were united for the first time into one empire, the capital of which was fixed at Honân. The last of the five contending races was soon after deposed by Ly-yuen, who in A.D. 622 founded the dynasty of Tâng. There is reason to believe that certain Christians of the Nestorian church first came to China about this time. It is recorded that foreigners arrived, having fair hair and blue eyes. According to the Jesuits, whom Du Halde has quoted, a stone monument was found by them in Shen-sy, with the cross, an abstract of the Christian law, and the names of seventy-two preachers in Syriac characters, bearing the date of A.D. 640. The dynasty of Tâng was put an end to by a powerful leader in the year 897, and the whole country was thrown into a state of war and confusion, with several aspirants to the sovereignty. This period, which lasted about fifty-three years, is principally distinguished by the incursions of the Tartar people at the eastern extremity of the Great Wall, who, being encouraged by the unsettled and divided state of the country, gave great trouble by their inroads. After a succession of civil wars, Tae-tsoo, the first emperor of the Soong dynasty, was raised to the throne by the military leaders, A.D. 950. The art of printing having been just previously invented (about 500 years before it was known to us), the multiplication of books became a principal cause of the literary character of the age of Soong. The Chinese however being much less warlike than learned, the eastern Tartars advanced apace; they took possession of a part of northern China, and threatened the whole country. They were destined soon to be checked, not by the Chinese, but by the Mongols, who inabhited the countries which extend from the north-western provinces of China to Tibet and Samarcand. They had already conquered India, and being now called in against the Kin or eastern Tartars, they soon subdued both them and the enervated Chinese, whom they had been invited to protect. The Mongols might be said to be masters of the northern part of modern China from the middle of the thirteenth century. Kublai Khan, finding himself possessed of the provinces bordering on the Wall, with Peking for his capital, sent his army against the last sovereign of the Soong dynasty, then a child. Little or no resistance was offered to the Tartars, who exercised great cruelty on the vanquished. The remains of the Chinese court betook themselves to the sea near Canton, and perished with the emperor, A.D. 1281. Notwithstanding the great qualities of Kublai Khan, which were calculated to lay the foundation of a permanent dominion, his successors of the Yuen race, as they are called, by their rapid degeneracy caused the empire to pass out of the hands of the Mongol race in a little more than eighty years' time. Enervated by the climate and vices of the south, they quickly lost the courage and hardihood which had put the country in possession of their ancestors; and Shun-ty, the ninth emperor in succession, was compelled to resign the empire to a Chinese. The new sovereign, who commenced the native dynasty of Ming, A.D. 1366, selected Nanking as his capital, erecting Peking into a principality for one of his younger sons, Yoong-lo. When this prince succeeded as third emperor of his family, the capital was finally transferred (A.D. 1408) to Peking; a principal reason perhaps being the necessity of keeping in check the Eastern Tartars, who had been joined by some of the refugees among the expelled Mongols. From this union sprung the Manchows, who were destined at length to expel the Chinese dynasty, and establish a permanent Tartar dominion. In the year 1618, Wan-liĕ, the thirteenth emperor of the Chinese dynasty, being on the throne, a war commenced with these Manchows: and the empire passed in 1644 to Shunchy, the first of the Ta-tsing race, of whom the sixth emperor is now reigning. Such is the brief summary of the principal revolutions in the history of this antient empire, which for nearly two centuries past has been governed by a foreign race, who had the sagacity to adopt the political and social system of a nation which so greatly out-numbered themselves.

Arts, &c.—Whatever may be the actual antiquity of the Chinese people, no doubt seems now to exist of their having been the authors of what are justly considered in Europe as three of the most important inventions or discoveries of modern times: the art of printing, the composition of gunpowder, and the magnetic compass. To these may be added two very remarkable manufactories, of which they were unquestionably the first inventors, those of silk and of porcelain. There cannot be the least doubt of the art of printing having been practised in China during the tenth century of our æra. The precise mode in which they operate is certainly different from ours, but the main principle, that of multiplying and cheapening books, by saving the time and labour of transcription, is altogether the same. The invention of powder, as compounded of 'sulphur, saltpetre, and willow-charcoal,' is carried back by the Chinese to a very remote date; but its particular application to fire-arms seems to have been European. The Chinese name has no reference whatever to guns, and simply implies *fire-drug*, which seems to show that the composition was applied by them merely to fire-works (in which they excel at present) and other harmless or useful purposes, long before their unwarlike spirit could have suggested the use of guns to themselves, or they could have borrowed the notion from Europe. With regard to the compass, the attractive power of the loadstone had been known to them from remote antiquity, but its property of communicating polarity to iron is for the first time explicitly noticed in a Chinese dictionary finished in A.D. 121. Under the head of 'Loadstone' appears this definition: 'A stone with which a direction can be given to the needle.' The same word (*chin*) is used by them to express the magnetic and the common working-needle, as among ourselves. Père Gaubil, in his History of the Tâng dynasty, states that he found, in a work written one hundred years later than the above, the use of the compass distinctly recorded. It is curious to contrast inventions of such high utility and importance with the very small progress which the Chinese have made in the sciences, as astronomy, geography, and mathematics, for which they were not ashamed to be indebted to the European missionaries. With regard to the fine arts, or those which minister rather to the pleasures than to the wants of mankind, it becomes necessary to make some allowances for the peculiarities of national taste. The arts of drawing and painting do not rank so high among the Chinese as among ourselves in Europe, and having therefore met with less encouragement they may be expected to have made less progress. In drawings where perspective is not very strictly required, as in representations of birds, insects, fruits, and flowers, they are eminently successful, and nothing can exceed the splendour and variety of their colours. In regard to the Chinese music, their instruments are mostly tuned in unison, and they have little or no idea of accompaniment. They have certain characters to express the name of every note in their very limited scale, and these they use in writing down their airs; but whether this mode of notation is indigenous, or whether they obtained it from the Jesuits, in imitation of the European method, is doubtful. It is indeed stated that the Emperor Kâng-hy was much surprised when Père Pereira pricked down the Chinese tunes as they were played, and repeated them afterwards. Their instruments are numerous, consisting of different species of lutes and guitars; flutes and other wind-instruments; an harmonicon of wires, touched with two slender slips of bamboo; bells and pieces of sonorous metal; drums, and a sort of clarionette which emits as nearly as possible the tones of the Scottish bagpipe.

Literature and Language.—The antiquity of Chinese literature is proportionate to that of their language, and has been of course greatly promoted and increased by the early invention of the art of printing, which they have now possessed for 900 years. Specimens of this literature in various departments have been afforded to Europe by the labours of Staunton, Davis, Morrison, Klaproth, and Rémusat, who followed up the earlier investigations of the Jesuits at Peking, and have enabled us to form a judgment regarding the merits of compositions, which for a long period were considered to be inaccessible, from the difficulties of the language in which they were written. In legislation, we possess a translation of the Penal Code of the empire; in politics and morals, the sacred books of Confucius and his followers; and, in Philology and Belles Lettres, we have a copious and well-executed dictionary of the language; several translations or abstracts of histories; the Dramas of the 'Heir in Old Age,' the 'Sorrows of Hân,' 'Le Cercle de Craie;' an elaborate treatise concerning their poetry; and the excellent novel or romance of the 'Fortunate Union.' The mastery which has thus been obtained of the language of China by several Europeans, among whom our own countrymen hold a conspicuous place, seems to prove that the rumoured difficulties attendant on its acquisition, from the alleged number and variety of the characters, are the mere exaggerations of ignorance. We may close this article with giving some account of so singular and original a language from Davis's work on China.

It appears that the theory of a universal medium for the communication of ideas, as conceived by Bishop Wilkins, has been realized by the Chinese. While the letters of our alphabet are mere symbols of sounds, the Chinese characters or written words are symbols of ideas, and alike intelligible to the people of Cochin-China, Japan, Loo-choo, and Corea, with those of China itself. As the best practical illustration of a written character, common to several nations who cannot understand each other's speech, Mr. Davis adduces the Arabic numerals common to all Europe. An Englishman, who could not understand what an Italian meant if he said *venti-due*, would comprehend him immediately if he wrote down 22. This advantage, which belongs to our numerals only, pertains to the whole language of the Chinese. The uniformity however in the written character does not prevent the existence of great diversities in the oral languages of the neighbouring countries and China, and even of the separate provinces of the latter country. These diversities are precisely analogous to the different pronunciation given to the same numeral characters in the various countries of Europe. To adduce the foregoing example, the number 22, which an Italian calls *venti-due*, a Frenchman pronounces *vingt-deux*, and an Englishman *twenty-two*, though all three write them just alike. It is in this manner that the universality of the Chinese language extends only to the written character, and that the natives of the two extremities of the empire, who read the same books, and understand each other perfectly on paper, are all but mutually unintelligible in speech. The roots, or original characters of the Chinese, are only 214 in number, and might indeed be reduced to a much smaller amount by a little dissection and analysis. These are combined with each other to form other words, or express other ideas, very much in the same way that the individual Arabic numerals are combined to express the infinite varieties of numbers. By a species of analogy they may be called the alphabet of the language; with the difference that exists between an alphabet of ideas, and an alphabet of sounds. To assert that there are so many thousand characters in the Chinese, is much the same thing as to say that there are so many thousand words in Johnson's Dictionary; nor is a knowledge of the whole at all more necessary for every practical purpose than it is to get all Johnson's Dictionary by heart, in order to read English. Prémare observes, 'that there is nobody who might not read and write Chinese, after he had once acquired a good knowledge of 4000 or 5000 characters or words.' The roots already mentioned serve, like our alphabet, for the arrangement of the words in the large Chinese Dictionary, a national work compiled by the most learned persons in the empire, more than a century since, by order of the enlightened monarch Kâng-hy. So ingenious and lucid is the arrangement, that to a practised person there is little more difficulty in turning to a word than, among ourselves, in consulting Johnson. From the principle on which the written language has been constructed, there has accrued to it a remarkable property noticed by the late professor Rémusat, in his paper 'On the State of the Natural Sciences among the People of Eastern Asia.' As the 214 roots, or radical characters, whose combinations with each other form the whole language, singly express or represent the principal objects or ideas that men have occasion to communicate in the infancy of their knowledge, they comprise within their number the heads of genera and classes in nature, and thus afford the elements and means of a philosophical system of arrangement. As their knowledge increased, a fortunate instinct (M. Rémusat observes) guided the framers of the written language, and led them, instead of forming characters altogether new, to express new objects by the ingenious combination of those elementary symbols which they already possessed. Among the roots, for instance, we find *horse, dog, metal,* the addition to which, of some other significant symbol, expressive of some peculiar property or characteristic, serves to designate the different species comprised under their principal genera.

In this manner, as M. Rémusat remarks, each natural object becomes provided with a binary denomination, inasmuch as the complex character is necessarily formed of two parts; one for the class, order, or genus: the other for the species or variety. Thus they express horse,—horse-ass—horse-mule; dog—dog-wolf—dog-fox; metal—metal-silver—metal-iron, &c. &c.—the elementary or generic words, horse, dog, metal, being those under which the compounds are arranged in the Dictionary. Much consideration is attached by the Chinese to the graphic beauty of their written characters. The advantage of simplicity constitutes the merit of our alphabetic writing: but that of variety and picturesque effect must fairly be claimed by the Chinese; as well as the peculiar characteristics of a universal medium of communication. The two most usual forms of their character are the printed and the written, besides which, there are the seal, or engraved form, and one or two others. The printed form (analogous to our Roman type) lays claim only to clearness and accuracy; but the written combines correctness with elegance. It may suffice to observe generally, that the grammar of the language is extremely limited. In the absence of all inflexion, of which their characters are utterly incapable, the relation of words to each other in a sentence can only be marked by their position. The verb, for instance, must always precede its object, and follow its agent. The plural number is denoted by the affix of mun to nouns—jin-mun, men; t'ha-mun, they; or by repeating the noun, as jin-jin, men. Either of these is rendered unnecessary when a specific number is prefixed, as san jin, three men. The genitive or possessive case is commonly marked by an affix, che, succeeding the noun like our 's, as T'hien che gen, 'heaven's favour—shoo che ken, 'the tree's root.' The comparison of adjectives is marked by affixes, as haou, 'good'—keng haou, 'more good'—ting haou, 'most good.' The tenses of verbs are denoted by auxiliaries, or expletives, as t'ha yew tso, 'he has done.' The cases of nouns and pronouns are determined by prepositions, as tsoong t'hien, 'from heaven.' The collocation of words in a sentence must of course be a matter of more consequence in Chinese than in those languages where the relations of different words to each other are marked by the distinctions of number, gender, case, and person, as shown by declension and conjugation. The *Notitia Linguæ Sinicæ* of the Jesuit Prémare may be recommended as the best Chinese Grammar ever written.

As before the arrival of the Europeans China was frequently divided into two or three states, the northern portion of it was called by the adjacent nations of Central Asia *Cathay*, and under this name it became known to the Russians and Mongols, whilst the inhabitants of India called the southern part *Chin*, under which name the Portuguese and other Europeans became acquainted with it. In the seventeenth century, and not before, it was ascertained that Cathay was China, and that the great town of Cambalù was identical with Peking. (Du Halde; Staunton; Lindsay; Davis's *China;* Ritter's *Asia.*)

CHINA-WARE. [PORCELAIN.]

CHINCHI'LLIDÆ (Zoology), a small natural family of Rodent (gnawing) animals, to which the attention of English naturalists was first called by Mr. Bennett, from whose writings the principal part of this article is compiled.

Order. RODENTIA.
Tribe. Herbivora. F. Cuvier.

Molar teeth without true roots, growing throughout life by means of a persistent pulp.

Family. *Chinchillidæ.* Bennett.

Upper incisors simple; molars, $\frac{4-4}{4-4}$, consisting of two or three tænial or riband-like bony lamellæ or plates, parallel with each other, entirely surrounded with a vitreous substance; the crowns exactly opposite to each other and flattened by attrition. The posterior limbs nearly twice as long as the anterior. The tail produced with long and somewhat bristly hairs above and at the tip. The *chinchillidæ* are gregarious and subterranean in their habits, and mild in disposition.

Genera. Lagotis.

Dental formula: incisors, $\frac{2}{2}$, molars, $\frac{4-4}{4-4}=20$. The incisors are sharpened, and each molar consists of three complete oblique plates. *Skull* arched posteriorly and above; the superior cellules of the tympanum inconspicuous. All the feet four-toed, the great toe being entirely absent; nails long and subfalcular. Ears very long. Tail long. Fur soft, but caducous.

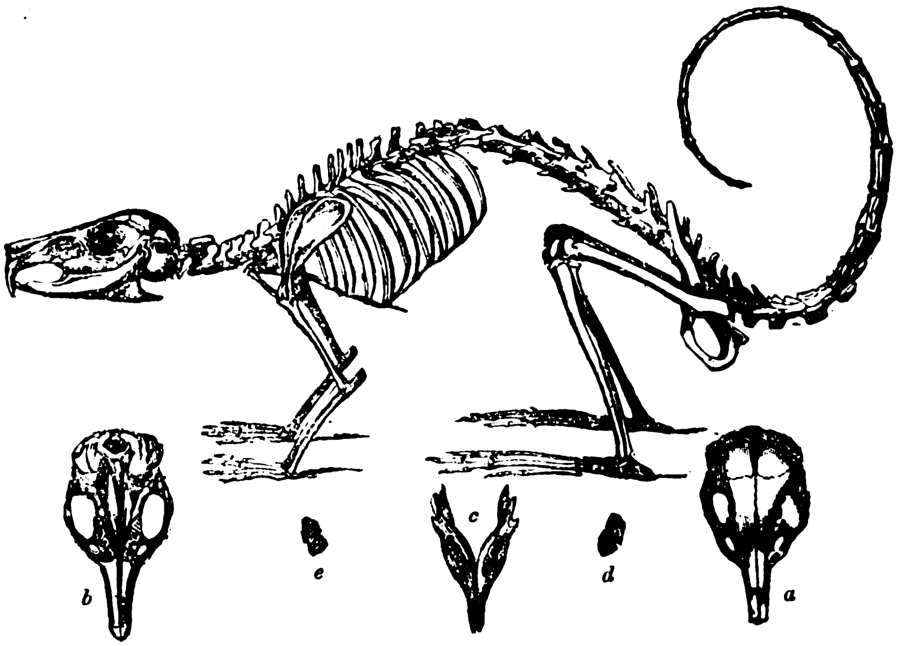
Example. *Lagotis Cuvieri.* Size, and much of the general form of the rabbit. Posterior limbs twice the length of the anterior: tail about equal in length to the body, excluding the head. Whiskers very numerous, closely set, jet black, ten or twelve of the longest on each side being exceedingly thick and rigid, and seven inches long. Ears nearly like a long parallelogram, rounded at the tip, three inches long and one broad, with the margins rolled in below, so sparingly furnished with short scattered hairs as to appear almost naked. Fore feet like the hinder, with four toes only, there being no vestige of a thumb; claws small, slightly sharpened, and entirely concealed by long and somewhat bristly hairs; those of the hinder feet similar in shape and rather larger, but that of the inner toe flattened, curved inwards, and exposed, the immediately adjoining hairs giving place to a tuft of about eight rows of short, stiff, horny, curved bristles, approaching nearly in rigidity to the comb-like appendage found in almost the same situation in the *Ctenomys Massonii* of Gray. A similar structure occurs in the *chinchilla.* The fur is beautifully soft, downy, and of considerable length, but so loosely attached to the skin that it readily falls off, unless handled with care. It is dusky at the base, and to within a short distance of the tip, where, for an extent of from one to three lines, it is dirty white, more or less tinged with yellowish brown. A few long black hairs, most numerous posteriorly, protrude through it. The general tone of colour is a mottled greyish ash. On the sides of the neck and body, where the tips of the fur merge more into yellowish-brown than on the back, and where they are also of greater length, as well as on the haunches and beneath, the latter tinge appears rather more predominant. There is little of the dusky colour visible on the under surface. The hairs of the tail below are extremely short, closely depressed, and of a brownish black; on its sides they are of two kinds, black and white; and this is also the case with the very long, rigid, and erectile hairs which form a crest along its upper surface. The very long, bristly hairs, which project in a tuft at the tip, are wholly black.

Mr. Bennett believes this species to be the *viscacha* of all the writers from Pedro de Cieça downwards, including Acosta, Garcilasso, Peter de Laet, Nieremberg, Feuillée, Ulloa, Vidauré, Molina, Schmidtmeyer, and Stevenson, who have stated that animal to be an inhabitant of the western or Peruvian acclivities of the Andes. M. de Blainville, Desmarest, and Lesson, are among the modern zoologists who have noticed the viscacha; Lesson, in his Manual, apparently confounding the eastern and western species, gives it as the *lepus viscaccia* of Gmelin, places it among the hares, and quotes Desmarest, as expressing his opinion in his 'Mammalogie,' that it ought to be the type of a new genus, under which the *chinchilla* might be perhaps arranged.

Cuvier, in the last edition of the 'Règne Animal,' says that the viscacha, as described by D'Azara, and according to the figures which he had seen and which were communicated to him by Mr. Brookes and Major Hamilton Smith, can scarcely be any other than a large species of chinchilla, with hair less long and soft; and he says that it is the animal described under the name of *Gerboise géante* (Giant Jerboa) by M. de Blainville in Desmarest's 'Mammalogie, and in the 'Nouv. Dict. d'Hist. Nat.,' and represented in the English translation of the 'Règne Animal' under that of *Marmot Diana.* Cuvier seems to be here speaking of the *Lagostomus* of Brookes, the other viscacha (of which we shall presently treat), and the *Dipus maximus* (*Gerboise géante*) of De Blainville, to include which and the chinchilla, M.M. Isidore Geoffroy St. Hilaire and Dessalines D'Orbigny had proposed in the 'Annales des Sciences Naturelles,' for November, 1830, the creation of a new genus—*Callomys.*

Mr. Bennett, in the concluding part of the first volume of the 'Transactions of the Zoological Society of London,' has recorded a second species, *Lagotis pallipes.* The fur of this, he observes, is perhaps even softer to the touch than that of *Lagotis Cuvieri;* a feel which is probably owing to its being less dense, on account of the comparative shortness of the hairs composing it; the fur of *Lagotis Cuvieri* imparting to the hand the sensation of fullness and consequent firmness, while that of *Lagotis pallipes* is yielding with its softness. The hairs in both species, especially those which form the mass of the fur, are wavy for the great part of their length, their tips only being straight; those of the middle of the sides measure, when their natural waves are not interfered with, three-quarters of an inch in *Lagotis pallipes,* and an inch and a quarter in *Lagotis Cuvieri.* In neither of these species, however, is the quality of the fur at all comparable to that of *Chinchilla lanigera.*

We have already observed that Mr. Bennett is of opinion that this species is the Peruvian viscacha of the authors above alluded to. The following is the English version (1709) of the passage in Pedro de Cieça's 'Chronica del Peru' (1554), descriptive of the habits of that animal:—'There is another sort of creature they call viscacha, about the bigness and resembling a hare, but that it has a long tail like a fox. These breed in stony places and among rocks, and many of them are shot with guns and crossbows, and taken by the Indians in gins (with the lasso), they being good to eat after hanging to tender; and of their hair or wool the Indians make large mantles, cloaks, or blankets, as soft as silk, and very valuable.' Ulloa's account (*Noticias Americanas,* 1772) is, in the opinion of Mr. Bennett (whose translation we adopt), the best history that has been given of its habits and manners. 'Taking the place of the rabbit, which is wanting in Peru, there is another kind of animal called viscacha, which is not found in Quito. In form, and in the colour of its fur, it is similar to the rabbit, but differs from it in having a long tail furnished with tufted hair (like that of the squirrel), which is very thin towards



[Skeleton of Lagotis Cuvieri *.]

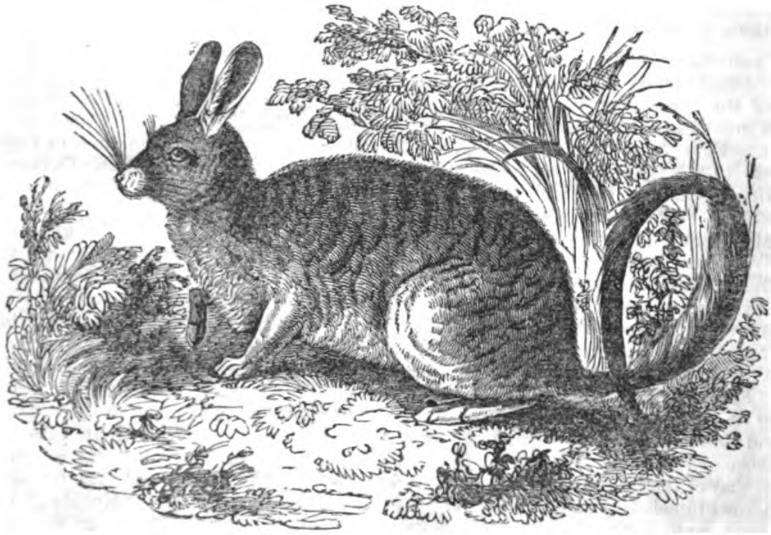
the root, but thick and long as it approaches the tip. It does not carry its tail turned over the head like the squirrel, but stretched out, as it were, in a horizontal direction; its joints are slender and scaly. These animals conceal themselves in holes of the rocks, in which they make their retreats, not forming burrows in the earth like rabbits. There they congregate in considerable numbers, and are mostly seen in a sitting posture, but not eating; they feed on the herbs and shrubs that grow among the rocks, and are very active. Their means of escape do not consist in the velocity of their flight, but in the promptitude with which they run to the shelter of their holes. This they commonly do when wounded; for which reason the mode of killing them is by shooting them in the head; as if they receive the charge in any other part, although much injured, they do not fail to go and die in the interior of their burrows. They have this peculiarity, that as soon as they die their hair falls off, and on this account, although it is softer and somewhat longer and finer than that of the rabbit, the skin cannot be made use of for common purposes. The flesh is white but not well flavoured, being especially distasteful at certain seasons, when it is altogether repugnant to the palate.' The author (supposed by some to be the Abbé Vidauré) of an anonymous Italian work on the natural history of Chile, extracts from which are given in the 'Journal de Physique' for 1779, has evidently confounded the eastern and western species; and his account, as Mr. Bennett well observes, is in several particulars apocryphal. Molina speaks of the employment of its wool among the antient Peruvians, adding, that the Chilians of the present day (his work was originally published in 1782, and reprinted with additions in 1810) use it in the manufacture of hats. Its burrows, according to the report of eye-witnesses, have two flats, communicating by a spiral staircase; in the lower it deposits its food, while it lives in the upper, which it seldom quits, except at night. It collects round the mouth of its burrow whatever has been left behind or lost by travellers: and its flesh, which is white and tender, is preferred to that of the rabbit or hare. But this account is liable to the same objections as that in the 'Journal de Physique.'



[Lagotis Cuvieri †.]

Chinchilla.

Dental formula: incisors, $\frac{2}{2}$, molars, $\frac{4-4}{4-4} = 20$, the molars generally consisting of three complete oblique plates, except the anterior lower molar, which has but two lamellæ, the anterior lamella being deeply bilobated. Skull posteriorly retuso-truncated, above depressedly flattened; cellules of the tympanum conspicuously inflated. Anterior feet five-toed: posterior feet four-toed, the nails small and subfalcular. The ears ample. The tail rather long. In addition to *Chinchilla lanigera*, which we select as an example, Mr. Bennett gives a second species, *Chinchilla aurea*, *Callomys aureus* of Isid. Geoff. St. Hilaire.

---

* From Mr. Bennett's figure, 'Zool, Trans.,' vol. i., part i.

† From Mr. Bennett's figure.

The length of the body of *Chinchilla lanigera* is about nine inches, and that of the tail nearly five. Its proportions are close-set, and its limbs comparatively short, the posterior being considerably longer than the anterior. The fur is long, thick, close, woolly, somewhat crisped, and entangled together, greyish, or ash-coloured above, and paler beneath. The form of the head resembles that of the rabbit; the eyes are full, large and black; and the ears broad, naked, rounded at the tips, and nearly as long as the head. The moustaches are plentiful and very long, the longest being twice the length of the head, some of them black and others white. Four short toes, with a distinct rudiment of a thumb, terminate the anterior feet; and the posterior are furnished with the same number, three of them long, the middle more produced than the two lateral ones, and the fourth, external to the others, very short and placed far behind. On all these toes the claws are short, and nearly hidden by tufts of bristly hairs. The tail is about half the length of the body, of equal thickness throughout, and covered with long bushy hairs; it is usually kept turned upwards towards the back, but not reverted as in the squirrels.' Such is the minute description of Mr. Bennett, who, in 1820, described the animal as the type of a distinct genus under its common name. Mr. Gray, in August, 1830, also described and gave an interesting account of its domesticated habits obtained from Mr. Hennah *.

Organization.—Mr. Yarrell, in February, 1831, gave to the Zoological Society of London the following account of the skeleton and parts of the *viscera* of one which died in the menagerie of the Society, premising that at the time of examination all the *viscera* had been preserved some months in a weak solution of spirit. 'The lungs are composed of three small lobes on each side. The heart is flattened in form from behind forwards, measuring $\frac{6}{10}$ths of an inch across its base, and but $\frac{4}{10}$ths in depth; the want of apex gives it a round and muscular appearance. The liver exhibits two large and equally sized lobes, and two smaller lobes. The stomach, a single cavity, measures from the entrance of the *œsophagus* round the great curve to the pyloric contraction five inches $\frac{1}{10}$ths, the greatest breadth 2 inches $\frac{3}{10}$ths, the depth, 1 inch $\frac{4}{10}$ths; the spleen is small and elongated. The length of the small intestines from the *pylorus* to the end of the *ilium*, 3 feet 10 inches; the *cœcum* and first portion of the *colon* are of large size; made up of three half circular convolutions, one central, with one of smaller dimensions on each outer side, containing numerous cells and divisions, strengthened by muscular bands and *septa*, the whole length of *cœcum*, *colon*, and *rectum*, measures 4 feet 10 inches. With the exception of the *cœcum* and commencement of the *colon*, which are voluminous, all the intestines are of very small calibre. The kidneys vary somewhat in shape; one measures $\frac{5}{10}$ths of an inch in length, and $\frac{3}{10}$ths in breadth; that on the opposite side is much more spherical. The specimen is female, and the uterine *cornua* measure each $3\frac{1}{4}$ inches in length.'

'Of the skeleton when mounted, the whole length, from the nose to the end of the tail, is 13 inches $\frac{6}{10}$ths; the upper surface of the *cranium* from the *occiput* to the inter-orbital space is triangular and flat, the width at the occiput 1 inch $\frac{1}{10}$th; of the inter-orbital space, $\frac{3}{10}$ths, the whole length of the head, 2 inches $\frac{3}{10}$ths; the mastoid processes and auditory cells of very large size; the external *meatus* also large, oval, directed upwards and backwards; the *zygoma* narrow and slender posteriorly, but deep and stronger at its junction with the malar bone, which has an ascending bony division between the orbits and temporal *fossæ*, the nasal bones narrow, convex, and of parallel diameter; the lower jaw is curved, broad, and strong; the course of the incisor teeth is visible, and the alveolar cavities of the molar teeth are well defined externally; the coronoid processes are wanting, apparently as if broken off during the preparation of the skeleton, but have obviously been of very small size; the condyle elongated from before backwards; the plate deep, and the posterior angle of considerable length. The exposed portion of the incisors measures $\frac{4}{10}$ths of an inch in length; the molar teeth are all made-up of three parallel portions, or bony *laminæ*, each portion invested with a thin coat of enamel, and closely united; the base of a molar tooth presenting six lines of enamel and three cavities; the anterior third of the first molar tooth on each side, above and below, is smaller than the other two portions, and gives to these teeth a triangular shaped crown; the posterior third portion of the last molar tooth on each side above, is nearly round, and gives an increase of surface to these also; in the molar teeth of the lower jaw the fold of enamel between the first and second portions of the bony *laminæ* of each tooth does not reach quite to the outer edge, and the two portions of bone appear therefore to be only partially separated. The direction of the parallel *laminæ* of all the molar teeth is not at right angles with the line of the maxillary bones, but inclining obliquely from without backwards. The length, from the *atlas* to the end of the tail, is 11 inches $\frac{4}{10}$ths; cervical

* Spicilegia Zoologica.

† From Mr. Bennett's figure.

vertebræ, 7; dorsal, 13; lumbar, 6; sacral 2, and caudal, 23. The *scapulæ* are small, measuring 1 inch from the external angle to the articulation with the *humerus*, the spine is but little elevated, the *acromion* ample, the clavicles perfect; length of the *humerus*, 1 inch $\frac{4}{10}$ths; the bone strong and furnished with an elongated crest descending from the head; from the *olecranon* to the carpal articulation, 1 inch $\frac{4}{10}$ths; the *ulna* and *radius* firmly anchylosed throughout the distal half of their length; thence to the longest of the five toes $\frac{4}{10}$ths of an inch. The ribs, 13 pairs. The bones of the *pelvis* slender and elongated; from the crest of the *ilium*, which is but little produced, to the inferior edge of the *ischium* is 1 inch $\frac{4}{10}$ths; the *ossa pubis* slight in structure, advancing but little; the *symphysis* elongated, and the *obturator foramen* of large size. The *femur* is straight, strong, and smooth, and measures 1 inch $\frac{4}{10}$ths; the *tibia* 2 inches $\frac{7}{10}$ths; the *fibula* is complete, and forms the external *malleolus*; from the *os calcis* to the end of the longest toe, 2 inches $\frac{1}{10}$th; the toes, four in number, of which the outer one is the shortest, the third from the outside, the longest; the second and fourth equal'

Yarrell remarks that in some previously published observations, he had stated that the *Chinchilla* appeared to be closely allied to Mr. Brookes's *Lagostomus*, but that the more complicated structure of the teeth, and the existence of an additional toe on each of the feet, require for the *Chinchilla* the generic distinction claimed for it by Mr. Bennett and Mr. Gray. He adds that the resemblance of the skeleton to that of the *Jerboa* is also remarkable, particularly in the form of the head, in the excessive development of the auditory cavities, and the small size of the anterior extremities compared with the hind legs; and that the true characters of the Chinchilla 'seem even now to be unknown to the French authors above referred to*, who appear to be acquainted with its skin alone, and never to have examined either its teeth, or the number of its toes. In these respects it deviates from the characters of their proposed genus (*Callomys*); a genus which cannot be adopted, inasmuch as it is composed of heterogeneous materials, and as the two types included in it have both previously been described and designated as distinct groups.'

We now go back to Mr. Bennett's interesting account, in 'The Gardens and Menagerie of the Zoological Society delineated†,' of this animal, which that author observes, notwithstanding the extensive trade carried on in its skins, 'might have been regarded until the last year almost as an unknown animal.'

The earliest account cited by Mr. Bennett is an English translation (London, 1604) of Father Joseph Acosta's 'Natural and Moral History of the East and West Indies,' published at Barcelona, in Spanish, in 1591. 'The Chinchilles is another kind of small beasts, like squirrels; they have a woonderfull smoothe and soft skinne, which they (the natives) weare as a healthfull thing to comfort the stomacke, and those parts that have neede of a moderate heate.' Sir John Hawkins, in his 'Voyage into the South Sea, A.D. 1593,' (London, small folio, 1622, reprinted in 'Purchas his Pilgrims,') says, 'Amongst others they have little beastes, like unto a squirrell, but that he is grey; his skinne is the most delicate, soft, and curious furre that I have seene, and of much estimation (as is reason) in Peru; few of them come into Spaine, because difficult to be come by, for that the princes and nobles laie wait for them; they call this beast Chinchilla, and of them they have great abundance.' Alonso de Ovalle, in his 'Historical Relation of the Kingdom of Chili' (Rome, 1646), calls them squirrels. 'The squirrels (Ardas) which are found only in the valley of Guasco, are ash-coloured, and their skins are in great esteem for the fineness and softness of the fur.' An anonymous Italian author, supposed by some bibliographers—erroneously, as Mr. Bennett thinks—to be the Abbé Vidauré, who published at Bologna, in 1776, a 'Compendium of the Geographical, Natural, and Civil History of the Kingdom of Chili,' speaks of the Arda (Spanish for a squirrel) as a species of rat, or campagnol, of the size of a cat, found only in the province of Copaipo, moderately docile, and covered with ash-coloured wool, as close and delicate as the finest cotton. Buffon, and that too, after quoting Feuillée's excellent description, confounded it with the *Chinche*, the most stinking of beasts. D'Azara corrected this error, but falls into another himself, in regarding the chinche of Feuillée and Buffon as his Yagouaré. Molina (Natural History of Chili—Italian, Bologna, 1782) describes the Chinchilla as a species of Linnæan *Mus*, under the name of *Mus laniger*. Gmelin adopted the appellation, but M. Geoffroy St. Hilaire considered that it ought to be regarded as one of his *Hamsters*. Zoologists generally took up this opinion, and Molina, in a second edition of his essay (1810), seems to have entertained it. 'The Chinchilla,' says Molina, 'is another species of field-rat, in great estimation for the extreme fineness of its wool, if a rich fur as delicate as the silken webs of the garden spiders may be so termed. It is of an ash-grey, and sufficiently long for spinning. The little animal which produces it is six inches long from the nose to the root of the tail, with small pointed ears, a short muzzle, teeth like the house rat, and a tail of moderate length, clothed with a delicate fur. It lives in burrows underground, in the open country of the northern provinces of Chili, and is very fond of being in company with others of its species. It feeds upon the roots of various bulbous plants which grow abundantly in those parts; and produces twice a year five or six young ones. It is so docile and mild in temper that, if taken into the hands, it neither bites nor tries to escape; but seems to take a pleasure in being caressed. If placed in the bosom it remains there as still and quiet as if it were in its own nest. This extraordinary placidity may possibly be rather due to its pusillanimity, which renders it extremely timid. As it is in itself peculiarly cleanly, there can be no fear of its soiling the clothes of those who handle it, or of its communicating any bad smell to them, for it is entirely free from that ill odour which characterizes the other species of rats. For this reason it might well be kept in the houses with no annoyance, and at a trifling expense, which would be abundantly repaid by the profits on its wool. The antient Peruvians, who were far more industrious than the modern, made of this wool coverlets for beds and valuable stuffs. There is found in the same northern provinces another little animal with fine wool, called the Hardilla, which is variously described by those who have seen it; but as I have never observed it myself, I cannot determine to what genus it belongs.' Upon this, Mr. Bennett, whose translation we have given, remarks that there can be little doubt that this animal is identical with the Chinchilla, the latter being frequently spoken of by the name of Arda, the same with Harda, the diminutive of which is Hardilla. Schmidtmeyer ('Travels into Chile over the Andes,' London, 4to, 1824) thus describes the animal. 'The Chinchilla is a woolly field-mouse, which lives underground, and chiefly feeds on wild onions. Its fine fur is well known in Europe; that which comes from Upper Peru is rougher and larger than the Chinchilla of Chile, but not always so beautiful in its colour. Great numbers of these animals are caught in the neighbourhood of Coquimbo and Copiapo, generally by boys with dogs, and sold to traders who bring them to Santiago and Valparaiso, from whence they are exported. The Peruvian skins are either brought to Buenos-Ayres from the eastern parts of the Andes, or sent to Lima. The extensive use of this fur has lately occasioned a very considerable destruction of the animals.'

Captain Beechey, R.N., on his return from his expedition to the north-west coast of America, presented a living specimen to the Zoological Society; and an entire skin, rendered particularly valuable in consequence of its having the skull preserved in it, was at the same time brought home by Mr Collie, the surgeon of Captain Beechey's ship, and deposited in the British Museum.

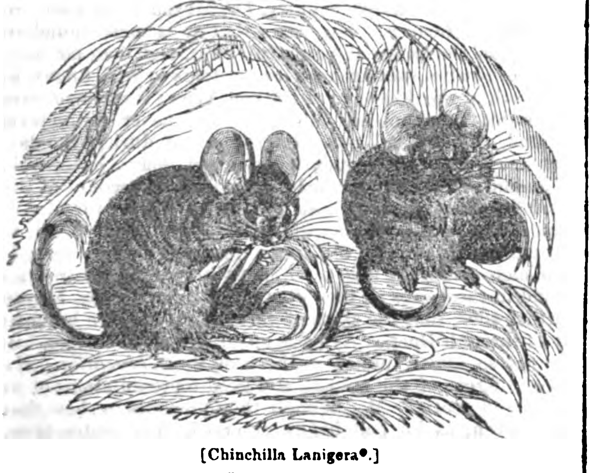
'To the account of its habits given by Molina,' says Mr Bennett, 'we can only add, that it usually sits upon its haunches, and is even able to raise itself up and stand upon its hinder feet. It feeds in a sitting posture, grasping its food, and conveying it to its mouth by means of its fore paws. In its temper it is generally mild and tractable, but it will not always suffer itself to be handled without resistance, and sometimes bites the hand which attempts to fondle it when not in a humour to be played with. Although a native of the Alpine valleys of Chili, and consequently subjected in its own country to the effects of a low temperature of the atmosphere, against which its thick coat affords an admirable protection, it was thought necessary to keep it, during the winter, in a moderately warm room, and a piece of flannel was even introduced into its sleeping apartment for its greater comfort. But this indulgence was most pertinaciously rejected, and as often as the flannel was replaced, so often was it dragged by the little animal into the outer compartment of its cage, where it amused itself with pulling it about, rolling it up, and shaking it with its feet and teeth. In other respects it exhibits but little playfulness, and gives few signs of activity; seldom disturbing its usual quietude by any sudden or extraordinary gambols, but occasionally displaying strong symptoms of alarm when startled by any unusual occurrence. A second individual of this interesting species has lately been added to the collection by the kindness of Lady Knighton, in whose possession it had remained twelve months previously to her presenting it to the Society. This specimen is larger in size, and rougher in its fur than the one above described; its colour is also less uniformly grey, deriving a somewhat mottled appearance from the numerous small blackish spots which are scattered over the back and sides. It is possible that this may be the Peruvian variety, mentioned in the extract from 'Schmidtmeyer's Travels,' as furnishing a less delicate and valuable fur than the Chilian animal. It is equally good tempered and mild in its disposition, and, probably, in consequence of having been exhibited in a public collection, is much more tame and playful. In its late abode it was frequently suffered to run about the room, when it would show off its agility by leaping to the height of the table. Its food consisted principally of dry herbage, such as hay and clover, on which it appears to have thriven greatly. That of the Society's original specimen has hitherto been chiefly grain of various kinds, and succulent roots. When the new-comer was first introduced into Bruton Street, it was placed in the same cage with the other specimen; but the latter appeared by no means disposed to submit to the presence of the intruder; a ferocious kind of scuffling fight immediately ensued between them, and the latter would unquestionably have fallen a victim had it not been rescued from its impending fate: since that time they have inhabited separate cages, placed side by side; and although the open wires would admit of some little familiarity taking place between them, no advances have as yet been made on either side. Such an isolated fact can, of course, have little weight in opposition to the testimony of Molina, that the Chinchilla is fond of company. It is nevertheless a remarkable circumstance, and deserves to be mentioned in illustration of the habits of these animals.'

---

* M.M. Isidore Geoffroy St. Hilaire and Dessalines D'Orbigny.

† Vol. i. 1830.

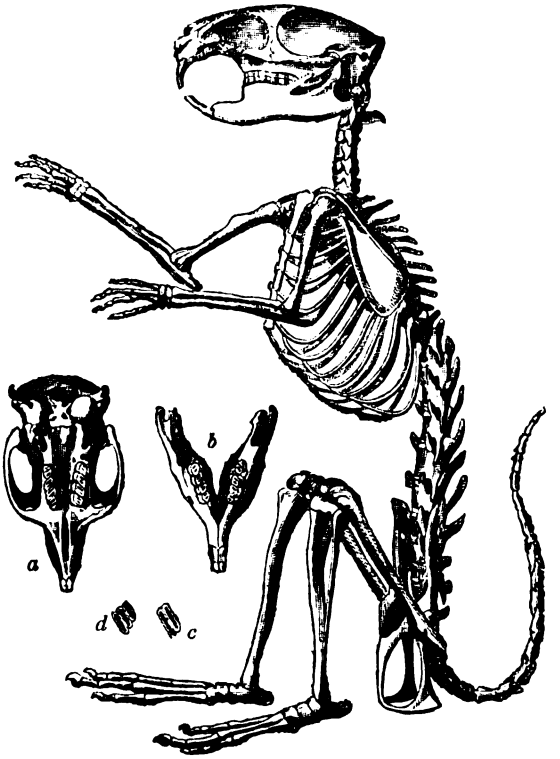
Utility, &c.—The fur is a considerable article of commerce. In muffs, tippets, linings to cloaks and pelisses, and trimmings for the same, it is sold extensively, and at a comparatively high price. There is now (August, 1836) a living specimen in the Garden of the Zoological Society, in the Regent's Park.



[Chinchilla Lanigera*.]

LAGOSTOMUS.

Dental formula, incisors, $\frac{2}{2}$, molars, $\frac{4-4}{4-4} = 20$. The incisors sharpened. The molars each consisting of two complete oblique lamellæ, the upper posterior one being trilamellar. Anterior feet four-toed, the thumb being altogether deficient, the nails small and falcular. Posterior feet three-toed, the nails produced, straight, and robust. Ears moderate. Tail moderate. Example. *Lagostomus trichodactylus*, Brookes.



[Skeleton of Lagostomus trichodactylus*.]

a, upper jaw; *b*, lower jaw; *c*, crown of the second molar tooth of the left side of the lower jaw; *d*, crown of the last molar tooth of the right side of the upper jaw.

In 1814 there was a living specimen of this animal at Exeter Change, where it was observed by M. de Blainville and M. F. Cuvier. The former described it in the 'Nouveau Dictionnaire d'Histoire Naturelle,' and the latter in the 'Dictionnaire des Sciences Naturelles,' under the name of *Dipus maximus*, Blainv., erroneously referring it to the Jerboas, and not suspecting its identity with the Eastern Viscacha, or Biscacho, an identity overlooked also by Mr. Brookes†, who obtained the specimen after its death, and prepared from it a stuffed skin and skeleton, which, on the breaking up of his museum, passed, according to Mr. Bennett's belief, into the hands of M. Temminck, who purchased them for the Leyden Museum. It had been figured, while living, in Mr. Griffith's 'Translation of the Règne Animal,' under the name of *Marmot Diana*, as before observed. MM. D'Orbigny, fils, and M. Isidore Geoffroy St. Hilaire, published in the 'Annales des Sciences' for November, 1830, a paper 'on the Viscacha and the Chinchilla, regarded as the types of a genus named *Callomys*, together with the description of a new species.' But M. Isidore Geoffroy has since seen reason to abandon his opinion of the generic identity of the two animals. In August, 1831, M. Lesson gave, in the 'Bulletin des Sciences Naturelles,' an extract from his 'Illustrations de Zoologie,' containing a new description of the Viscacha, under its original name of *Lagostomus trichodactylus*, which M. Kuhn had previously restored to the animal. The 'Illustrations' give a figure of the animal, and representations of its feet and of its muzzle.

Mr. Bennett is clearly of opinion that it is the Viscacha, described by so many travellers as colonizing the vast plains eastward of the great chain of the Andes. Dobrizhoffer, Jolis, D'Azara, Proctor, Head, Miers, and Haigh, all mention it. Capt. (now Sir Francis Head) gives a picture of these animals, sitting solemnly at the entrance of their burrows, quite in his peculiar style. Biscacho is the name he assigns to them, and, according to his account, the Biscachueras, or Biscacho burrows, which perforate the plains, are terrible traps for the unwary horsemen.

---

* Goldfuss has figured it in his 'Naturhistorische Atlas,' under the name of *Lagostomus laniger* of Wagler, referring as a synonym to *Eriomys Chinchilla* of the Frankfort Museum.

* From Mr. Brookes's figure in the 16th vol. of the 'Linnæan Transactions.'

† 'Linn. Trans.,' vol. xvi., p. 95.

Habits.—We select the accounts of two foreign travellers (whose works are not in the hands of every one) of the habits of this species. 'The Biscacha, called by the Abipones Nebelaterek,' says Dobrizhoffer in his curious *Historia de Abiponibus* (Viennæ, 1784), 'digs its burrows in the more elevated parts of the plains with so much art, that no aperture is left by which the rain can penetrate; and these burrows are divided into distinct settlements, numerous families inhabiting the same locality. On the surface of the ground are several entrances to the burrows, at which, towards sunset, they are seen seated in crowds, diligently listening for the sound of any person approaching. If everything remains quiet, they seek their food in the obscurity of the night, and commit grievous devastation on the neighbouring fields, devouring both wheat and Indian corn with extreme avidity, and when either is to be had, despising grass. For this reason the stations of the Biscachas are rarely to be seen in the desert plains, but indicate with certainty the near neighbourhood of the Spanish settlements. I have often wondered never to have seen the Biscacha in the territories either of the Abipones, or the Guaranis, although well supplied with all kinds of crops. They daily heap up, at the entrances of their burrow, dry bones, chips of wood, or whatever other refuse they may meet with, but for what purposes they collect such things it is impossible even to conjecture. The Spanish colonists amuse themselves with hunting them; pouring many buckets of water into their subterraneous retreats, until, to avoid drowning, the animals come forth into the plain, where, no means of escape being afforded them, they are killed with sticks. Their flesh, unless when very old, is not considered despicable even by the Spaniards.' The Abbé Jolis dwelt for twelve years in South America, and made three journeys into the remote districts of the interior. His work, 'Saggio sulla Storia Naturale della Provincia del Granchaco' (Faenza, 1789), is so little known, and his description, in some particulars, differs so much from that of Dobrizhoffer, that we give Mr. Bennett's translation of it. 'The Biscachas live in society, in burrows, under ground, which they form for themselves, excavating in all directions to the extent of a mile in circumference, with various exits and separate retreats, in which the old live distinct from the younger. The soil in which these are usually made is that which is hard and barren, and destitute of everything, but with bushes (boscaglie) at no great distance, and pasture of tender grass, roots, and the bark of trees. They collect around their retreats bones, dried leaves, and whatever they find in the neighbourhood: if anything is missing in their districts, it is to be found with certainty piled up in these situations the following day. As they are animals that avoid the light, having little power of vision, they are not to be seen in the day-time, unless at dawn, or towards evening after sunset. The night, and especially when the moon shines, is the proper time for seeking their food. Those among the Biscachas which are called Chinchillas, and which may be said to belong to the first species, inhabit only the mountains and cold situations; in size they are like a rabbit, and are clothed with a fine long fur. Their agility is surprising; they are seen leaping from rock to rock as if they had the faculty of flight. The others, indicated above, inhabit the level country, in warm situations..... Fierce and courageous, they defend themselves with all their might against the dogs, and sometimes even attack the legs of the hunters. I shall speak in my travels, as a fitter place, of the three curious modes in which they are driven out of their retreats; that is to say, with water, with fire, and by rubbing sticks together.'

But neither of those authors mentions the somewhat anomalous companions with which the Biscachos are associated, and we select, from the travels of Proctor, Head, Miers, and Haigh, the account of the first-named traveller, which, as Mr. Bennett observes, gives nearly all the particulars which are to be found in the rest. 'The whole country, from Buenos Ayres to San Luis de la Punta, is more or less burrowed by an animal between a rabbit and a badger, called the *biscacho*, which renders travelling dangerous, particularly by night, their holes being so large and deep, that a horse is almost sure to fall if he steps into one of them. The *biscacho* never ventures far from its retreat, and is seldom seen till the evening, when it comes out to feed, and hundreds may be observed sporting round their holes, and making a noise very similar to the grunting of pigs. Their flesh is much liked by the people, and they are remarkably fat, and on that account, when caught at any distance from their holes, are easily run down; they will however defend themselves from a dog a considerable time. The holes of these animals are also inhabited by vast numbers of small owls, which sit, during the day, gazing at the passing travellers, and making a very ludicrous appearance. The parts of the road most frequented by the *biscacho* are generally overrun by a species of small wild melon, bitter to the taste; whether it thrives particularly on the manure of the animal, or whether the *biscacho* chooses his hole nearer this running plant, does not seem to have been ascertained.'

In March, 1833, Dr. Meyen sent to the Imperial Academy Naturæ Curiosorum, the second part of a series of zoological observations, made during a voyage round the world, containing a revision of this family, for which he adopts from Wiegmann the name of *Lagostomi*, and to which he refers six genera; viz., *Pedetes*, *Lagostomus*, *Eriomys*, *Chinchilla*, *Galex*, and *Lagidium*; and he enumerates three distinct species of *Lagostomus*. His paper was published towards the end of 1833, in the 'Nova Acta Acad. Cæs. Nat. Cur.' His views differ widely from those of Mr. Bennett, which however we have retained, under the conviction that they are well founded, or, at least, unshaken by the observations of Dr. Meyen. As however confusion may arise from the discrepancy, we think it due to give Mr. Bennett's remarks on the paper in the last volume of the 'Zoological Journal.' 'As regards the South African genus *Pedetes*, Ill. (or *Helamys* of M. F. Cuvier),' says Mr. Bennett, 'I can by no means concur with the German zoologists who have proposed to associate it with the South American family of *Chinchillidæ*, although, as I have already stated in my paper in the Zoological Society's Transactions, p. 62, it seems in many of its characters to approach *Lagostomus*. I am still uncertain as to its true position, which I continue to think we are not yet furnished with sufficient materials to determine; but I am convinced that its relation to the *Chinchillidæ* is not one of near affinity.' 'The differences in the relative proportion of the limbs, in the elongated claws of its anterior extremities, in the character of its fur, and above all, in the structure of its teeth, forbid, as I have there stated, a close approximation.'

'The genus *Lagidium* of Dr. Meyen is synonymous with my *Lagotis*; and the species named by him *Lagidium Peruvianum* appears to be identical with *Lagotis Cuvieri*. The ascertainment of its habitat on the elevated plateaux of Peru confirms the accuracy of my decision, unassisted by any evidence as to locality, regarding its identity with the *Viscacha* of Peruvian travellers. Of its habits, as witnessed by himself in its native country, Dr. Meyen gives some interesting particulars. He states that it is most abundant just below the limits of perpetual snow, and does not form those extensive subterranean excavations so well known as the work of the *Viscacha* of Buenos Ayres; it was moreover invariably found among the rocks, and never on the level ground. On several occasions it was shot during the day, but was seen most frequently at sunset, being excessively abundant, although pursued with avidity on account of the good flavour of its flesh, which, however, is not so tender as that of the hare. The fabrication of stuffs from its wool, so general in the time of the Incas, has now entirely ceased; and such stuffs are only to be met with among the rarities found in the tombs of the antient inhabitants. Dr. Meyen further adds, that the skins of these Viscachas are brought to us through Buenos Ayres as an article of commerce, but are not so highly prized as those of the *Chinchilla*. He gives a figure of the animal, and good representations of its skull and teeth.' Mr. Bennett then proceeds to show that Dr. Meyen, as he had before observed, enumerates three species.

Of *Lagostomus*, the two first of these represent the animals respectively figured by the late Mr. Brookes and by M. Lesson, under the name of *Lagostomus trichodactylus*, which Dr. Meyen considers as distinct on account of the differences observable between the two figures. These consist in the small and curved claws of the hinder foot in the former, contrasted with the large size and nearly straight direction of the same organs in the latter; in the habit; and in the shape of the tail. The misapprehension may serve to show how dangerous it is to rely on figures only in the discrimination of species. As regards the first presumed distinction, Mr. Bennett has observed (p. 57 of his paper), that 'in this particular the figures given by Mr. Brookes are defective, as exhibiting the claws far smaller and more curved than is natural.' A reference to the descriptions of M. F. Cuvier and M. de Blainville, both taken from Mr. Brookes's specimen while living, will confirm the accuracy of this observation; the latter in particular (Desm. *Mammal.* No. 508), describing the middle toe of the hinder foot as furnished with a very strong claw. On the second point, the habit, it need only be observed, that both figures were taken from stuffed skins by artists who had never seen the living animal; and who could consequently give only their own conjectural ideas of its natural appearance when in a living state. On the third, it may be observed, that some obscurity is to be feared, M. de Blainville having described the animal while living as having its tail truncate and mutilated, and Mr. Brookes's skin and skeleton being both provided with perfect tails. A fine skin, now in the possession of the Zoological Society, agrees in all essential particulars with the animal figured by M. Lesson; and as far as Mr. Bennett's recollection goes, with that which once formed a part of Mr. Brookes's Museum. The figure given by the latter should only be considered as correct in so far as it is borne out by the descriptions of MM. F. Cuvier and De Blainville, which should be referred to in connexion with it.

The third species of *Lagostomus*, enumerated by Dr. Meyen, is the *Eriomys Chinchilla* of Dr. Lichtenstein, figured and described in the 'Darstellung neuer oder wenig bekannter Säugethiere,' a work unknown to Mr. Bennett when his paper was published; and Mr. Bennett acknowledges that the figure there given so closely resembles the true *Chinchilla lanigera* in all its prominent features, that he should not have hesitated to refer it to that animal, had it not been accompanied by separate representations of the feet, which offer only four toes on the anterior, and three on the posterior extremities. Dr. Meyen, however, quotes as a synonym *Callomys laniger* of M. Isidore Geoffroy and the younger D'Orbigny; and Mr. Bennett, therefore, observes, that there can be little doubt that they overlooked the small and almost rudimental inner toe both of the fore and hind feet; the identity of this animal with the *Chinchilla lanigera* of Dr. Rousseau being unquestioned by the Parisian zoologists, who have ample opportunities of comparing them, and M. Geoffroy himself having subsequently admitted the generic distinction of the *Chinchilla* (his *Callomys laniger*) from his genus *Callomys*, the true *Lagostomus*. The *Chinchilla* of Mr. Gray, the fourth genus of the family, according to Dr. Meyen, being beyond question the only *Chinchilla* yet noticed by English zoologists, and consequently identical with that figured in Mr. Griffith's edition of Cuvier's Animal Kingdom, and Mr. Bennett's Chinchilla. The author last named sees no reason for doubting that the *Eriomys* of Vander Hoeven, Dr. Meyen's fifth genus, is founded on the same species.

Galea, Dr. Meyen's sixth genus, is founded on a skull discovered at the entrance of a burrow belonging, according to Mr. Bennett, in all probability to a yet undescribed species of the family *Chinchillidæ;* as the character of the animal inhabiting the burrow, which was only seen at a distance, appeared closely to resemble a true *Chinchilla.* The skull and teeth, however, observes Mr. Bennett, according to the figures, belong to the *Caviidæ*, with none of the known genera of which do they altogether agree, although they approach most nearly to *Kerodon.*

Mr. Bennett concludes by stating that Dr. Meyen's *Dendrobius Degus* is his (Mr. Bennett's) *Octodon Cumingii*, described in March, 1832; and he observes that Molina's description of his *Sciurus Degus* differed so greatly from the animals from which Mr. Bennett's description was taken, and which were living in the garden at the Regent's Park, in September, 1834, that he hesitated to quote that name as a synonym, adding that he is not quite sure whether Dr. Meyen states of his own knowledge or on Molina's authority, that his (Dr. Meyen's) animal is called *Degus* by the natives of Chile. If the former, the synonym, he remarks, can be of course no longer doubtful.

As dates are of consequence in an investigation of this nature, the following note to Mr. Bennett's paper on *Lagotis pallipes* is given:—'Dr. Meyen's paper was communicated to the Imperial Academy in March, 1833: mine was communicated to the Zoological Society in May of the same year. But the genus *Lagotis* had been characterized by me, so far as its external characters could be ascertained from the living specimen, at a meeting of the Committee of Science and Correspondence, in June, 1832; and the name then given was affixed, throughout the life of the animal, to the cage in which the Society's animal was kept.'

CHINESE ARCHITECTURE. The architecture of the Chinese may be considered unique in its style. Their buildings differ also in construction from those of Europe and the rest of Asia. The peculiar character of Chinese architecture is displayed in their royal palaces, their temples, bridges, triumphal arches, and also in their houses and sepulchres. The materials employed are wood, of which that most in use is the nan-mon, a kind of cedar: stone, marble, bricks, bamboo, and glazed or porcelain tiles are also employed. The construction of houses is directed by a public functionary, whom we may not inaptly designate a district surveyor. Every one is obliged to build his house according to his rank, and for every house a certain size and details are fixed. The ordinary habitations have one floor, and we may presume the houses of the common people in the towns to be crowded, and badly ventilated, since the police force the people to sleep in the open air during the dog-days, lest they should be suffocated. The houses called heon, that is of many floors, were once very much the fashion, and some were built about 211 feet high. Wooden columns, so placed as to support the roof, are common, and are from eight to ten diameters in height. They are fixed on stone or marble bases, but have no capitals; an architrave of wood placed on the top of them runs through the wall of the house, and a beam which is carried through the upper part of the column, and passes through the wall also, is connected with the architrave on the outside of the house. The roofs, which are slightly constructed of bamboo, are often double, and resemble one roof rising out of the other: they turn up at the eaves, at the angles of which are hung grotesque figures of dragons, &c. The columns and beams are often made of precious woods, and are inlaid with ivory, copper, and mother-of-pearl. Not the least singular appearance in a Chinese house is the door, which is often a complete circle; the window frames and sashes are formed of small pannels of various forms moulded out of clay, and neatly joined together. The sills of doors are of stone. The wood of the nan-mon is said to last more than a thousand years. Stone and marble, though in abundance, are more rarely used than wood, brick, and tile. The palaces of the kings are built on large masses of alabaster as a foundation. The palace of Pekin is on an immense scale, 2513 feet by 3235 feet. It is spoken of by the missionaries as presenting a very imposing appearance. The palace, which is divided into a number of courts, is composed of towers, galleries, porticos, halls, and immense buildings: each court is more superb than the other as you approach towards the last court, the residence of the king, which is the richest of all. In Pekin, and in the environs, there are said to be 10,000 temples: those which are within the walls of the palace are beautiful, and some are magnificent.

Almost all the temples differ in their plan. That of Honang presents as you enter, first, a very extensive court with three rows of trees which lead to an open vestibule, the ascent to which is by a step; this vestibule leads to another, in which are four colossal seated figures, formed of stucco; this last vestibule leads into another great court surrounded with colonnades and rooms behind them for the priests. The court contains three square temples, equidistant, and set upon a plinth along the centre of the court; they are two stories high, and surrounded with columns both above and below, and filled with idols. The priests perform their religious ceremonies in these buildings. At the four corners of the court are other smaller and somewhat similar edifices but without columns, in which the chief priests reside. Under the colonnades and between the rooms of the ordinary priests, there are four chambers occupied by idols. Two smaller courts are placed on each side of the centre of the large court; these are surrounded by the kitchens, refectory, and hospitals· all the buildings are covered with green varnished tiles.

The towers which we call pagodas are very common in China. The most celebrated is at Nankin, and is commonly called the Porcelain Tower. The plan is octagonal, with a diameter of 40 French feet, each face being 15 French feet wide; it has nine stories. There are others of round, square, and hexagonal forms, built of stone, brick, porcelain, and wood: each story has a roof and an elaborate balcony railing; at the angles of the roof beds are hung. The pagoda at Kew is a poor representation of a pagoda, having neither the colours nor brilliant decorations of the Chinese. It was built by Sir William Chambers.

Triumphal arches, erected to the honour of women as well as men, are very common; and there is a great rage for them in China. In the smaller towns they are built of wood, and the workmanship of many is very coarse. At Ming-po the triumphal arches have three gates, two small and one large, the larger one being in the centre. The door-posts are of stone. The entablature consists of three or four faces, and the architrave is morticed and tenoned, although it is of stone. Mouldings are seldom used in these faces, except in the highest or the highest but one; instead of a cornice there is a projecting roof which crowns the whole. The ornaments of some of these arches consist of men, birds, and flowers, and the ground is cut away so that the day-light is seen behind: the three openings are also arched. Most towns have extensive walls, high enough to hide the buildings, except the pagodas or towers, and wide enough to ride on horseback. The walls of Pekin, which are built of brick, are 42 feet 6 inches high, and they have small square towers at every 200 feet. In some places there are long inclined planes for the cavalry to ascend. The isolated castle of Tien-sing-foo, at the confluence of the Pei-ho and Eu-ho rivers, is of a square form and built of slate-coloured bricks; the walls are ramped or inclined inwards; the basement is of stone, and the entrance, which is arched with stones, is at some height from the ground, with a square window on each side. The top of the castle has battlements, and below them is a large torus-moulding on a level with the terrace; just above the torus are small semicircular arches to let the rain run off the terrace. The parapets between the battlements are each pierced with two small holes, and a small guard-house with the roof having the usual turned-up eaves is built on the top of the terrace.

The Chinese varnish their columns, colour their roofs, and plaster their walls with stained substances of brilliant colours. Ornaments in China are little more than mere flat cuttings out, like the laced railwork of their balconies. The Chinese roofs, which for their form are unique, are considered by some to have been derived from the tents of this people in their nomadic state.

The tombs and monuments of China exhibit a variety of architectural designs, often resembling the familiar forms of their buildings; even the double roof is carved on some mausoleums. The common people have only a cone of earth with trees on the summit, not unlike the barrows in Wiltshire. Several forms of tombs are given in Alexander's 'Costume of China.' The forms are round, square, hexagonal, and octagonal, and the form of the coffin is also imitated.

Chinese architecture does not appear to be founded on the best principles. As in all semibarbarous nations, outward show is the great object, and thus the brightest coloured houses are thought the most beautiful.

For a general account of Chinese bridges, see BRIDGE; and for the Great Wall, see CHINA, p. 74. (Alexander's *Costume of China*, and his drawings in the museum of the East India House; Sir William Chambers's *Architecture; Il Costume Antico e Moderno*, plates; the *Encyclopédie Methodique* contains a very long article on China.)

CHINGLEPUT, a tract of country forming part of the grants obtained by the East India Company in 1750 and 1763, from the Nabob of Arcot, and known in the annals of the Indian government as the Company's Jaghire. This tract is bounded on the N. by Nellore district; on the W. by the districts of northern and southern Arcot; on the S. by the southern division of Arcot; and on the E. by the bay of Bengal; it therefore forms part of the province of the Carnatic, and is included in the presidency of [illegible] of the Chingleput district is generally bad; detached rocks of granite are continually met with in the fields, and interfere with the processes of cultivation. The district was invaded by Hyder Ali in 1768 and 1780; in the latter of these invasions the country was so ravaged that many parts were wholly depopulated, and for some years after presented to the view of the traveller only the ruins of houses and temples, and the bones of people who had been massacred. Shortly after this invasion the inhabitants of the less desolated parts experienced a famine which caused so considerable an emigration that nearly the whole country was deserted. In 1794 the district was formed into a collectorate under Mr. Place, and a gradual improvement took place, so that in 1823, according to returns made by the collector to the Madras government, the population amounted to 363,129 persons, of whom 190,243 were males, and 172,886 females. The principal towns in the collectorate are Chingleput and Conjeveram. Chingleput is situated in 12° 46′ N. lat., and 80° 2′ E. lon., on a stream which at a short distance west from the town falls into the Palaur. The town is distant 38 miles S.S.W. from Madras; it is irregularly built, and the houses are of mean appearance. The fort is of considerable extent, and has been of great strength; of late years it has been allowed to go into decay, and is garrisoned by a few invalids. In 1751 it was taken by the French under Dupleix, and in the following year was retaken by a small detachment under captain, afterwards lord Clive.

Conjeveram, called by the natives Kunji, is situated in a fertile valley watered by the small river Wegawutty, in 12° 49′ N. lat., and 79° 48′ E. long. The town is built in a straggling manner, and resembles a series of villages interspersed with extensive gardens and plantations. The streets, which are wide and regularly laid out, are planted on each side with cocoa-nut trees and bastard cedars. The houses are only one story high; they have mud walls and are roofed with tiles. Each house is built in the form of a square, with a small court in the centre. The buildings extend for between five and six miles; round the whole is a hedge of the Agave Americana, which has been found useful as a defence against irregular troops. A considerable part of the inhabitants are weavers, and employ themselves in making red handkerchiefs, turbans, and cloths adapted for the dresses of the natives. Conjeveram is also the residence of numerous Brahmins belonging to temples dedicated to Siva and Vishnu, which are much frequented. The pagoda of Siva is a large building said to contain 1000 pillars, many of them elaborately sculptured. The pagoda dedicated to Vishnu Conjee is not so large, but is more highly venerated. It was from this building that the town obtained its name of Conjeveram. There are many other pagodas, dedicated to various Brahminical deities. There are large tanks near to the different pagodas; for one of these, lying on the west side of the great pagoda, it is said the gods collected water from three millions of rivers. Every Brahmin who visits the place for the first time must perform his ablutions in this tank, and spend money in charity; the sums thus raised being in fact applied to the support of the Brahmins belonging to the temple.

(Mill's *History of British India*; Buchanan's *Journey through Mysore, Canara, and Malabar*; Heyne's *Historical and Statistical Tracts on India*; *Report of Committee of Commons on Affairs of India* 1832.)

CHIO'NEA (Dalman), a genus of Dipterous insects belonging to the section *Tipulariæ terricolæ*.

Only one species is yet discovered of this genus, but this is remarkable both in its structure and habits. It is less than half an inch in length; the head is of a brownish-yellow colour; the thorax and abdomen are ashy-brown; the latter is of an oval form and rather hairy; the legs are very long, rather thick and covered with hairs, not unlike the legs of a spider, and of a yellowish colour. It is perfectly destitute of wings, and is found upon the snow in the woods of Sweden throughout the winter. The generic characters are:—Body apterous; joints of the palpi nearly equal; antennæ setaceous, ten-jointed, and covered with fine hairs at the extremity; the abdomen of the male terminated by a forcep-like appendage composed of two horizontal jointed processes, and that of the female is terminated by a boring instrument, or ovipositor, consisting of two valvules, placed one upon the other, of which the upper one is the longer, and composed of two plates.

Upon turning to the article BOREUS, it will be found that there is another insect which, though it belongs to a different order (*Neuroptera*), resembles this species in its habits of appearing during the winter, and crawling upon the snow, as well as in being apterous, a character which is of rare occurrence in either tribe.

CHIOS, called by the modern Greeks, Khio, and by the Italians, Scio, is an island of Asiatic Greece, near the W. coast of Asia Minor. It faces the peninsula of Clazomenæ and Erythræ, which is formed by the gulf of Smyrna on the N., and that of Samos on the S. Chios lies at the entrance of the Gulf of Smyrna, and is separated from the main land by a channel about 8 miles wide. Its length from N. to S. is about 30 miles, and its greatest breadth about 10. It is mountainous, especially in the N. part, the principal summit of which, called Mount Pelinæus, consists of a long line of bare rocks. Strabo reckoned 400 stadia from the N. extremity of Chios to the nearest point of Lesbos. The oldest settlers, according to tradition once current in the island, were Pelasgi from Thessaly. Chios was afterwards one of the twelve Ionian states founded by the European colonists from Greece; the population that settled there was not pure Ionian, but mixed. (Strab. 633. Herod. i., 142.) The dialect of the inhabitants is said by Herodotus to have been the same as that of the people of Erythræ. In the great sea-fight between the Ionian Greeks and the Persians, (B.C. 494) which resulted in the entire defeat of the Greeks, the people of Chios furnished 100 ships, and fought bravely. After the battle the Persians took possession of the island, which suffered in nearly the same way that it has again suffered in our own time: the cities and temples were burnt, and all the handsome young females carried off.

The principal towns of the island in antient times were Chios, Posidium, Phanæ, which had a good port and a temple of Apollo, Notium, Elæus, and Leuconium. Ion, the dramatic writer, the historian Theopompus, and the sophist Theocritus, were natives of this island. Chios was also one of the places that claimed Homer as a native.

After the close of the Persian war, B.C. 480, the island passed successively under the dominion of the Athenians, the Macedonians, the Romans, and the Byzantines. The Genoese took it in 1346, and it was governed for a long time by the Genoese family of Giustiniani. Solyman the Great took it in 1566. In 1694 it was taken by the Venetians, but was soon after retaken by the Turks, by whom it was treated with especial favour, being allotted as a kind of dowry to the Sultana mother, who sent her officers to collect the mastic gum which is found in great abundance in the S. district of the island, and which constitutes a valuable commodity, being much used at Constantinople, and especially by the ladies of the seraglio for chewing. Under the protection of the Sultana mother, the people of Chios were safe from the vexations of the pashas and other arbitrary chiefs; they had their own magistrates, and lived in comparative freedom and security. The island accordingly prospered, and Tournefort, Dr. Chandler, Olivier, and other travellers, agree in representing it as a garden inhabited by a happy people. Its inhabitants amounted to more than 100,000, of whom nearly 30,000 lived at Khio, the capital, a handsome town built in the Italian style, with a castle raised by the Genoese, on the E. coast of the island. Khio is at the foot of Pelinæus, and occupies the site of the antient town of Chios. It had a college with fourteen professors, in which between 400 and 500 youths of the various Greek islands received their education, a printing-office, and a good library. The establishment was supported by voluntary contributions of the Chiote merchants, many of whom were wealthy, and carried on an extensive commerce with Italy and other countries.

Chandler speaks with rapture of the beauty and the simple graceful manners of the young females of Chios, at the time of his visit. When the Greek insurrection broke out, the Chiotes, a peaceful race, and far from the theatre of war, remained quiet, until a party of turbulent Samiotes and other Greeks from Candia, half partizans, half pirates, landed upon the island in 1822, and excited or rather obliged the people to join the insurrection. The sequel is well known. The capadan pasha came with a large force, the Samiotes escaped by sea, the poor Chiotes made hardly any resistance, but were slaughtered by thousands, their wives and children were carried away and sold as slaves, and the town was burnt. A traveller who visited the island in 1828 describes the melancholy appearance of that once thriving and beautiful place. 'We walked through long streets that contained nothing but the ragged skeletons of houses, and heaps of fallen masonry; grass, weeds, and nettles were growing in the crevices of the marble halls, in the ruined churches, in the but lately busy streets; and to give an idea of the utter desolation of this once populous town, we started a covey of partridges in the Strada dei primati, or principal street. In the town and the villages of the island there were at that moment about 15,000 Greeks who had escaped from the slaughter and had returned under the assurance of protection of the new Pasha Jussuf, the scanty remnant of a population of 100,000.' (Macfarlane's *Constantinople in* 1828.)

The wine of Chios is celebrated as among the best in the Levant, and it had the same reputation in the time of Strabo. The island produces also cotton and silk, besides fruit in abundance. A great number of tame partridges are bred on the island. Marble quarries are mentioned by Strabo as being worked; and Chandler speaks of a marble quarry near the town of Khio.

CHIPPENHAM, a parish, parliamentary, and municipal borough, and market town, in the hundred of Chippenham, Wiltshire, on the Bristol Avon, 86 miles west from London. The parish contains about 6900 acres, being upwards of six miles in length from east to west, and varying in breadth from one to two miles. The parliamentary borough, which returns two members, was extended under the Reform Act, and includes the parishes of Chippenham, Hardenhuish, and Langley Burrell, and an extra-parochial district which was formerly the forest of Chippenham. The population of the parish in 1821 was 3506; in 1831, 4333: of the extended borough, in 1831, 5270. The population of the town is estimated at about 1700. Under the Corporations Reform Act, the municipal borough has four aldermen and twelve councillors, but is not divided into wards.

Chippenham is an ancient town, but it was not incorporated till the reign of Mary. Its name is derived from its market, for which it has been long famous. The Avon is not navigable for several miles below Chippenham; but a branch of the Wilts and Berks canal is brought into the town from a distance of about two miles, by which a considerable trade, principally in coals, is carried on. A great traffic also arises from the town lying on the London and Bristol and Bath road. The great western railway will pass within a quarter of a mile of the market-place.

The market has recently been changed from Saturday to Friday, and a handsome building, called the Market-House, (over which is an extensive room, used for public meetings), has been erected by Joseph Neeld, Esq., at present (1836) one of the members for the borough. There is a monthly market for the sale of cattle and cheese: four annual fairs, for cattle and horses, are also held; and during the present year (1836) wool fairs have been established.

The town has recently been lighted with gas and paved, under an Act obtained in 1834. With the exception of some very dilapidated buildings in the centre of the town, the houses are generally well built, either with freestone or brick.

There are two manufactories, one for woollens, and the other for silks, at present at work: the latter is of recent establishment, but the former has been for many years the staple fabric of the town: the number of manufactories in that branch was formerly considerable, but for several years their number declined, and has been now reduced to one.

A savings' bank was established in 1822, which, on the 20th of November, 1835, held the sum of 22,521*l*. A literary and scientific institution has recently been set on foot.

A court of requests, for the recovery of debts not exceeding 40*s*., is held here every six weeks; its jurisdiction extends over the hundreds of Chippenham, Damerham North, and Calne. The living of Chippenham is a vicarage, with the rectory of Tytherton Lucas annexed, in the gift of Christ Church, Oxford. In addition to the church, (a venerable Gothic edifice, almost in the centre of the town), Chippenham contains four chapels, not connected with the establishment.

A bridge over the Avon, and certain causeways in the neighbourhood, are kept in repair by the corporation, who some years since widened the bridge at a considerable expense; it is well paved and lighted.

A free school, for the education of twelve poor children, is (with other charities) under the management of the corporation; the stipend allowed to the master by the foundation is 5*l.* 15*s.* per annum, with a residence. There is a daily and Sunday school for poor children (which is well attended), in connexion with the National School Society, and there are also Sunday schools in connexion with the various dissenting chapels. A trifling endowment for a Sunday school for the instruction of girls in the principles of the church of England was left in the year 1724, by the Rev. Robert Cock, vicar of the parish, who, by his will, gave the whole of his property to trustees for that purpose. A monument is erected to his memory in the chancel of the church. There are several other charities.

Some mineral springs have been found in the vicinity of Chippenham.

The antient abbeys of Stanley and Lacock are within three miles of Chippenham; the former is converted into a farm-house, but the latter has fallen into the hands of the Talbot family, who have preserved, and made it their family seat.

The antient forest of Chippenham and Pewsham is destroyed, although the latter place is still provincially called 'the Forest,' and the roads leading from it to the town retain the names of Wood Lane and Timber Street.

A union, under the Poor Law Amendment Act, has been formed of Chippenham and twenty-eight surrounding parishes, comprising a population, according to the census of 1831, of 19,265 persons, and an area of 56,371 acres. (*Communication from Chippenham*, &c.)

CHIPPEWAYS. [CREES.]

CHIROCEPHALUS. [BRANCHIOPODA.]

CHIRONECTES. [LOPHIADÆ.]

CHIRO'NOMUS, a genus of Dipterous insects of the family *Tipulidæ*. This genus was established by Meigen, and is principally distinguished by the following characters:—Fourth joint of the palpus longer than the rest; antennæ thirteen-jointed, in the male, and furnished with long hairs; the antennæ of the female are six-jointed, and the hairs are short; the anterior legs are inserted at some distance from the others, and the anterior tarsi are generally very long; the wings when closed lie parallel and they have three posterior cells; the body is long, slender and hairy.

Mr. Stephens, in his catalogue of British insects, enumerates upwards of eighty species of this genus: they are all of small size, frequent marshy situations, and very much resemble gnats. The worm known to anglers by the name of blood-worm is the larva of one of the species of this genus—the *Chironomus plumosus*. This worm is about half an inch in length; the body consists of numerous segments, and is furnished at the tail with several appendages which constitute the breathing apparatus. It is seen during the summer months on the mud near the edges of ponds and ditches; when thus seen however it is only shifting from one place to another, its natural locality being in the mud, where it may generally be found in great numbers, living for the most part under water. This larva is much sought after and devoured by birds and fishes; but during this last summer (1836) we discovered that it had a very formidable enemy in an insect of its own order. A fly, which closely resembled the house-fly, was observed in great abundance on the mud which had just been left by the retiring water, and we found them assembled in little groups of five or six, in the act of extracting the blood-worms from their holes, using the proboscis for this purpose; but no sooner was the worm fairly dislodged than a battle ensued, for each apparently wished to have the worm to itself; those that kept possession sucked out the fluids from the worm.

The pupa is of a brownish colour; the body is cylindrical, the head, thorax, wings, and legs are inclosed in separate sheaths, and, with the exception of the two fore-legs, lie in a close and compact mass; the fore-legs, covered by their sheaths, project from each side of the thorax. In this as well as in the larva state, the animal lives in the water. The breathing apparatus consists of two appendages, one on each side of the thorax, and each is composed of five branches which spring from a common centre.

When the insect is ready to quit its pupa case, it gains the surface of the water, and there remains suspended for some little time* with the disc of the thorax slightly protruded; this part bursts down the middle, and the insect, which is hairy, and hence does not easily wet, places its feet upon the surface of the water, where it floats (if the weather be calm) with the greatest safety. We observed, upon taking one upon our finger, that the wings are at first opaque and white, and filled with a fluid; but in a minute this fluid was expelled, and the sides of the wings collapsed and became transparent. The fluid thus ejected we perceived on our finger beneath the insect, but could not ascertain from what part of the wing or body it made its escape.

The perfect insect is of a pale ash colour, and is a little larger than the common gnat, which it resembles. This, as well as others of the genus, is remarkable for its habit of carrying the two fore-legs in a horizontal position: they project in front, and might be mistaken for antennæ; these latter organs however are very beautiful, and in the males resemble litle plumes.

CHI'ROTES, a genus of Saurians separated by Cuvier, and, according to him, resembling the *Chalcides* in their verticillated scales, and the *Amphisbœnæ* still more, in the obtuse form of their head; but distinguished from the first by their want of posterior feet, and from the last by their possession of anterior limbs. The same author adds, in a note to the last edition of the 'Règne Animal,' that the genera which terminate this order of Saurians are interposed in various manners between the ordinary Saurians and the genera which are placed at the head of the order Ophidians to such a point, that many naturalists are now of opinion that the two orders ought no longer to be separated, or rather that one order should be established, comprising on the one part the Saurians, with the exception of the *Crocodilidæ*, and on the other the Ophidians of the family *Anguidæ*; but he observes that there exist, among the fossil forms of the antient calcareous beds, two very extraordinary genera (*Ichthyosaurus* and *Plesiosaurus*), which, with the head and trunk of a Saurian, have feet attached to short limbs and formed of a multitude of small articulations conjoined so as to form a kind of paddle or fin, like the anterior paddles or fin-feet of whales. These ought, he adds, to form a very distinct family. In their osteology they approach the Saurians, properly so called, much nearer than the crocodiles, with which Fitzinger associates them in his family *Loricata*, though in the fossils there is no trace either of scales or of the tongue, the two parts on which the characters of the *Loricata* rest.

These Bimanous reptiles, as Cuvier terms them, include, according to him, but one species, which is a native of Mexico. This is the *Bimane cannelé* (*Chirotes canaliculatus*) of Cuvier, *Bipède cannelé* of Lacépède, *Chamæsaura propus* of Schneider, and *Lacerta lumbricoïdes* of Shaw. The animal has two short feet with four toes on each (and the vestige of a fifth) sufficiently organized internally, and attached by means of *scapulæ*, *clavicles* and a small *sternum*; but the head, the vertebræ, and, in short, all the rest of the skeleton resemble that of the *Amphisbænæ*.

Chirotes canaliculatus is about the size of a human little finger, and from eight to ten inches long (French). It is of a flesh-colour and covered with about 220 demi-rings on the back, and as many under the belly, which meet, in alternating, on the side. The tongue is but little extensile and is terminated by two small horny points. The eye is very minute. The tympanum is covered with skin and invisible externally. Above the vent are two lines of pores.

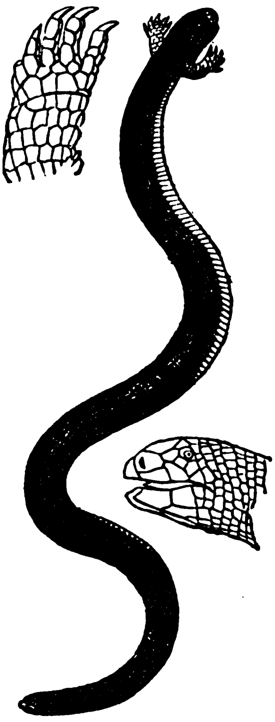
---

* Discussions have arisen on the means which this animal possesses of suspending itself at the surface of the water without motion, its specific gravity being supposed to be greater than water.

Messrs. Kirby and Spence account for it by a kind of propelling power which the centre of the thorax possesses, and state that this part being thus protruded and drying, the attraction of the air to the dry portion of the thorax is sufficient to overcome the slight difference in the specific gravity between the animal and the element; but it is further stated that if a drop of water fall upon the insect at this time it will immediately sink.

We have kept these insects in a glass jar for the purpose of observing their habits, and are very much inclined to doubt that the specific gravity of the pupa is greater than that of the water at the time just previous to the transformation from pupa to the imago state. Indeed at this time it appeared that they could not keep *from* the surface, unless they were in motion. Whenever we approached the jar, being at the top, they immediately descended by a quick zigzag movement of the body; but upon our remaining quiet for a moment they ceased all motion and rose to the surface again. We imagine that at this time the animal within having become partially disengaged from the pupa case, the space between the two is filled with air, that this would be sufficient to overcome the difference of specific gravity between the animal and the water, and that there would most probably be more air in the region of the thorax than elsewhere; and hence this part is protruded from the water.

Cuvier says that he only detected one large lung and the vestige of a small one, as in the majority of serpents.



[Chirotes canaliculatus.]

CHI'RUS, a genus of fishes of the section *Acanthopterygii*, and family *Gobioides*. The species of this genus have the body considerably elongated, furnished with ciliated scales, and the mouth not deeply cleft; the teeth are small and conical, but the most remarkable character consists in the body being furnished with several longitudinal lines of pores, similar to the ordinary lateral line. Some of the species have appendages over the eyes, as observed in the *Blennies;* their ventral fins have each five soft rays: the spines of the dorsal fin are slender, and this fin extends nearly the whole length of the back.

Cuvier says that it is with hesitation that he places this genus with the family above-mentioned, and that it will probably one day form the type of a separate family. All the species as yet discovered inhabit the seas of Kamtschatka—they are included in the genus *Labrax* by Pallas, who describes several of the species in the 'Memoirs of the Academy of St. Petersburgh,' vol. ii., 1810.

CHISMOBRANCHIA'TA (Zoology), De Blainville's second order of his second sub-class, *Paracephalophora Monoica*. The following is his definition of the order. *Organs of respiration* aquatic, branchial or pectinated, situated at the anterior part of the back, in a large cavity communicating with the ambient fluid by a wide oblique anterior slit. *Mouth* toothless, but provided with a long lingual riband-like organ. *Shell* either none, or internal, or external, very much depressed, with a very large entire aperture, and without any pillar (*columella*).

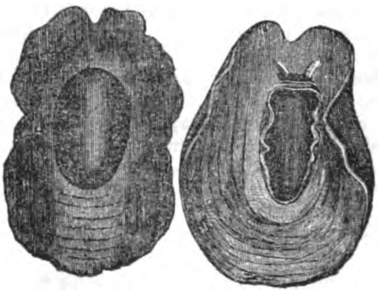
This definition is incorrect, in so far as it states that in some instances there is no shell; for *Coriocella*, the only genus described by De Blainville as being without any shell, has a horny one, as Cuvier observes, though it is very delicate and flexible, and nearly membranous. Cuvier, who places three of the genera, *Sigaretus*, *Coriocella*, and *Cryptostoma*, under his *Capuloides*, a family of his order *Gasteropoda pectinibranchiata*, observes that De Blainville places the greater part of the *Capuloides* under his non-symmetrical *Hermaphrodite Paracephalophora*, or *Calyptracians;* but that they appear to him (Cuvier) to be all Diœcious.

The geographical distribution of this order, which, according to De Blainville, is marine and probably herbivorous, is wide.

Genera.—Coriocella.

Body elliptical, very much depressed, having the borders of the mantle very delicate, notched in front, and spreading out very largely on all sides. *Foot* oval, very small. *Head* scarcely distinct; two *tentacula*, hidden under the shield, of some size, but short and contractile. *Eyes* at the external base of the *tentacula*. *Back* somewhat rounded, and according to De Blainville—but this, as we have already seen, is an error—without any shell, external or internal.

Example.—*Coriocella nigra*, Blainv. The only species of the genus, and described by De Blainville from a specimen in his collection. Locality, Seas of the Isle of France. Cuvier places this and the two following genera under his *Gasteropoda pectinibranchiata.*



[Coriocella nigra.]

Sigaretus.

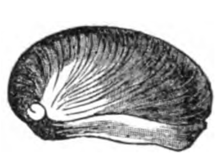
Shell more or less thick, flattened, with an ample and round aperture and but little spire, the whorls of which increase very suddenly; and enveloped during life in a spongy shield, which considerably encompasses its borders as well as the foot, and which is the true mantle. In front of this mantle there is a notch and a demi-canal, which serve to conduct the water into the branchial cavity. The tentacula are conical, and the eyes are placed at their external base. The male organ, according to Cuvier, is very large.

De Blainville thus subdivides the genus:

a. Species with a very delicate and smooth shell.

Example.—*Sigaretus convexus.*

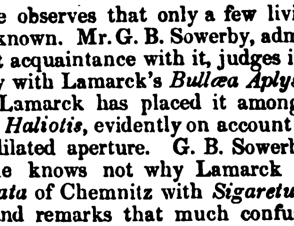
[Sigaretus convexus, seen from below.]



[Sigaretus convexus, side view.]

b. Species with a thick and solid shell.

Example.—*Sigaretus haliotoideus.*



[Sigaretus haliotoideus.]

De Blainville observes that only a few living species of this genus are known. Mr. G. B. Sowerby, admitting that he has but a slight acquaintance with it, judges it to belong to the same family with Lamarck's *Bullæa Aplysia*, and *Dolabella*, though Lamarck has placed it among his *Macrostomata*, near to *Haliotis*, evidently on account of its general form and its dilated aperture. G. B. Sowerby further observes, that he knows not why Lamarck has arranged *Nerita cancellata* of Chemnitz with *Sigaretus* rather than with *Natica*, and remarks that much confusion seems to reign in Lamarck's synonymy of his *Sigaretus haliotoideus*, inasmuch as he quotes figures of several very distinct shells for it.

Sigaretus has been found at depths varying from five to fifteen fathoms on sandy bottoms.

Fossil Sigareti.

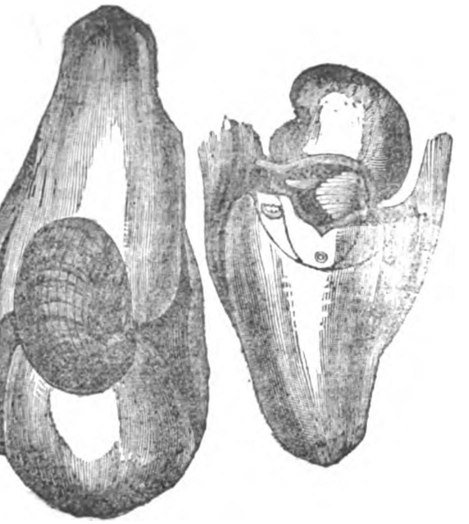
Defrance enumerates three fossil species, one from the

Plaisantin, one from Grignon, and another from the environs of Bourdeaux. G. B. Sowerby says that the fossil species are few and rare, and that they occur in the London clay at Barton, and in the contemporaneous formations in France and Italy. The species in the Calcaire grossier at Grignon, he adds, has a small umbilicus. Deshayes in his 'Tables' gives eleven living species, and four fossil (tertiary); one, *Sigaretus depressus*, living in the seas of the Molucca islands. The fossils occur in the Pliocene, Miocene, and Eocene periods of Lyell.

Cryptostoma.

Shell very like that of Sigaretus, carried with the head and abdomen, which it covers, upon a foot four times its size, cut almost squarely behind, and which produces anteriorly a fleshy and oblong part, which makes nearly one-half of the mass. The animal itself has a flat head, two tentacula, and a large pectinated branchia on the *plafond* of its dorsal cavity. The male organ is placed under the right tentaculum.

Example.—*Cryptostoma Leachii.*



[Cryptostoma Leachii.]

De Blainville, who separated the genus, says that he knows two species, both from India, and adds, that perhaps some species of Lamarck's *Sigaretus* belong to them. G. B. Sowerby, who identifies *Cryptostoma* with *Sigaretus*, states that as far as the differences in the shells themselves warrant it, his opinion is decidedly against the separation of De Blainville's *Cryptostoma* from the latter genus; and adds, that he does not think the animals sufficiently different to render the propriety of separating them very clear. He afterwards says, 'Upon examination of the specimens in the British Museum, we are convinced that De Blainville's *Cryptostoma Leachii* is the same as one of the two shells which Adanson calls *Sigaret:* his *Crypt. breviculum* is probably the other; but this we cannot ascertain, because the shell has been taken away from the specimen in the British Museum. We have no doubt, however, that the *Crypt. breviculum* of De Blainville is a female specimen of Cuvier's *Sigaretus*, given by him to Dr. Leach. It is to be regretted that Cuvier has not given any description of the shell of his *Sigaretus*, so that it is impossible to ascertain whether or not it be identical with either of Adanson's shells; it is perhaps needless to add, that unless it can be identified with one of them, it ought not to be considered as a *Sigaretus*. Its animal is certainly very different from that of *Cryptostoma Leachii*, which we believe to be identical with one of Adanson's.' Cuvier, in the last edition of the 'Règne Animal,' retains De Blainville's genus *Cryptostoma*, and places it next to *Coriocella*. He adds in a note, that besides the species in the British Museum (*Cryptostoma Leachii*, Blainv.), he possesses another (*Cryptostoma Carolinum*, Cuv.), sent from Carolina by M. L'Herminier. The genus does not appear in Deshayes's list.

Oxynöe.

Body gastropod, with a large dorsal shell, anterior, bulliform, and with a simple spire. *Foot* narrow. *Branchiæ* marginal, striated transversely. *Mantle* widened into two lateral wings. *Tentacula* two, not retractile.

Example.—*Oxynöe olivacea.* De Blainville, who seems to consider this genus somewhat apocryphal, observes that he only knows it from the little that Rafinesque, who described it in the 'Journal de Physique,' says of it; and adds, that he only places it in the position given to it, because M. Rafinesque states that it only differs from *Sigaretus*, because the shell is external; adding that, nevertheless, if the *branchiæ* are disposed, as Rafinesque describes them, the difference must be much greater. Rang, who speaks with approbation of this remark by De Blainville, places it under his unclassed genera. Cuvier does not notice it.

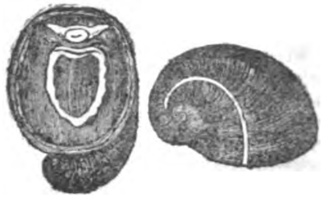
The next genus in De Blainville's arrangement is *Stomatella*, but as he places *Stomatia* with the sea-ears, and as we agree with G. B. Sowerby that *Stomatia* and *Stomatella* do not differ sufficiently for generic distinction, the reader will find their description under HALIOTIDÆ.

Velutina.

Animal oval, sufficiently protuberant (bombé), hardly spiral; border of the mantle simple anteriorly, and double for the whole of its circumference; the internal lip thickest and tentacular. *Foot* thick. *Tentacula* large, obconical, distant, with a small frontal veil between them. *Eyes* black, sessile at the external side of the base of the tentacula. *Mouth* large, at the extremity of a sort of muzzle. *Respiratory cavity* large, without any trace of a tube, and containing two unequal pectinated *branchiæ;* orifice of the ovary at the base of the male organ, situated at the root of the right tentaculum. Muscular attachment of a horse-shoe shape, very slight behind and open before.

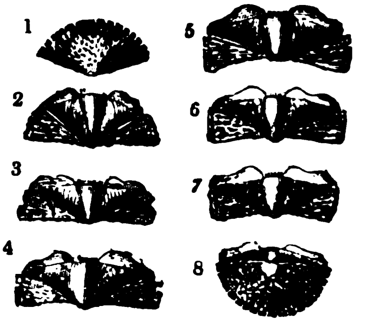
Shell, external with an epidermis, patelliform, with a small lateral spire, and without a columella. Aperture large, the edges almost continuous, and sharp: the right border united to the left by a lamellar calcareous deposit.

Example.—*Velutina capulöidea, Helix lævigata*, Linn. De Blainville observes that he established this genus from an individual provided with its shell, which he owed to the generosity of Defrance. He adds that he knows but one species from the coast of England, which is very probably the same of which Müller speaks under the name of *Bulla velutina*, and which Lamarck erroneously regarded as the analogue of his *Sigaretus haliotoideus;* and that Mr. Gray has also proposed the genus under the same name.

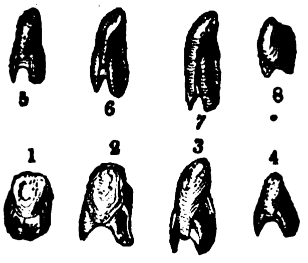


[Velutina capulöidea.]

CHITONS. CHITON TRIBE. CHITONIDÆ. A natural family of Gastropods, *Oscabrions* of the French, affording the only known instance of a protecting shell formed of many portions, or, as they have been somewhat incorrectly termed, valves, often in contact and overlapping each other, but never truly articulated. This anomalous structure is the probable cause of the various wanderings of those who have, each according to his own view, assigned the *Chitonidæ* their place, upon the faith of a too great value for this multiplication of shelly plates, composing a shield, or coat of scale armour for the soft parts. The following cut will give some idea of the structure of this shelly covering.



[Shelly plates or valves of Chiton.]



[Shelly plates, or valves of Chitonellus.]

These plates are bound together by a coriaceous border, which, as we shall presently see, is either plain, or beset with bristles, spines, &c.

The early naturalists took these shells for the peculiar armour of certain serpents, a conclusion to which they were doubtless helped by the love of the marvellous, so strongly shown in the accounts of the older travellers. By degrees the true condition of these mollusks became better known; and the opposite opinions of Linnæus and Adanson divided the naturalists of their age. The former arranged these shells among his multivalves, a class entirely artificial, and like all artificial classifications comprising the most heterogeneous forms. Adanson, on the contrary, took nature for his guide, and carefully observing the animal itself, while he regarded the shell as of comparatively small importance, placed *Patella* and *Chiton* side by side in his method. But the Linnæan school long reigned paramount; and Adanson's labours were comparatively forgotten, when Cuvier began to reform the crude state in which he found the *Mollusca*, and Lamarck and others aided in the work. Cuvier, who made anatomical investigation the basis of his opinions, at once pronounced in favour of Adanson. Lamarck afterwards adopted the same conclusion, but not till he had previously placed the Chitons at the end of the Acephalous Mollusks, between *Fistulana* and *Balanus*. Poli, in his magnificent work on the *Testacea utriusque Siciliæ*, in giving the anatomy of a Mediterranean species, became a valuable ally; for, although he still retained Linné's class of Multivalves, and although in his anatomical details he said nothing of the nervous system, a branch of animal organization essentially necessary to be known for assigning an animal its true place, he demonstrated enough clearly to show that *Chiton* bore no relation to the other Multivalves of Linnæus. M. de Blainville, however, resting upon the generative faculty of the *Chitons*, proposed, in opposition to these views of Cuvier and Lamarck, which had been adopted by almost all zoologists, to form a subtype of Mollusks under the name of *Malentozoaria*, in which each of the Linnæan genera, *Lepas* and *Chiton* constitute a class; the first, the *Lepadians* or *Lepadicea*, the second, the *Polyplaxiphores* or *Polyplaxiphora*. These almost singular views of De Blainville have not prevailed among zoologists; and Cuvier, in the last edition of the 'Règne Animal,' arranges the Chitons at the side of the *Patellæ*, forming from these two genera, his small family of *Cyclobranchians*.

Deshayes, in the article *Oscabrion*, in the 'Encyclopédie Méthodique,' enters at large into the organization of the Chitons, and discusses with much learning and acuteness the conflicting opinions of Cuvier and De Blainville.

The following is a summary of Deshayes's observations.*

Digestive organs. No projecting ***head***, in which the Chitons resemble the ***Phyllidians***. No ***tentacula***, which are replaced by a kind of veil which surrounds the mouth. *Eyes*, as in many other Mollusks, the *Pteropoda*, for example, wanting. ***Mouth*** and ***Œsophagus***, furnished with a very long tongue rolled spirally, and armed with horny teeth, a good figure of which is given by Poli. Stomach, intestine, and liver, like those of the other gastropods. Vent at the posterior extremity of the body, as in the Phyllidians, ***Doris***, &c.†

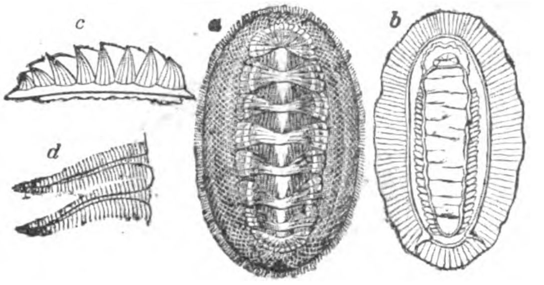
Respiratory and Circulating Organs. The ***branchiæ*** of the Chitons consist of a range of small triangular leaflets placed, as in ***Patella*** and ***Phyllidia***, in the furrow which separates the foot from the mantle. The ***heart*** is situated posteriorly* in the mesial and dorsal line: it is symmetrical, and composed of a single ventricle and two auricles.

Organs of Generation. According to De Blainville, an ovary only, which, instead of having, as in the other mollusks, a single exit, has two external issues, one to the right, the other to the left. Deshayes observes upon this, that though he has made minute anatomical investigations, he has found it impossible to find the second issue of the organs of generation, but he acknowledges that the species which he dissected were small†.

Nervous System. Proved by Cuvier not to differ from that of other mollusks properly so called. It consists of what may be termed a complete œsophagian ring, and of various branches, which are given off divergingly towards the several organs.

Locomotive Organs. The oval foot, more or less wide, according to the species, extends the whole length of the animal.

Shell. Eight narrow, transverse, calcareous pieces, overlapping each other, and strongly implanted on each side in a thick and fibrous border of the mantle, which surrounds the whole body, and is sometimes, as we have observed, naked, but more generally covered with small scales, spines, or hairs. These pieces are not immoveable, as the animal can roll itself up or stretch itself out again for the purpose of progression or adhesion. To work this machinery, there are three muscles given off from the first piece to the second, three others given off from the second to the third, and so on throughout, so as to make the mechanism of this scale armour complete. One of these muscles occupies the mesial and dorsal line, the other two are lateral and oblique. The growth of the shell is analogous to that of the other mollusks.



[Animal of Chiton Squamosus.]

a, the animal and shell seen from above; *b*, the animal seen from below; *c* side view of the shell and animal in a creeping or adhering state; *d*, portion of branchiæ magnified.

The chitons then resemble the other mollusks: 1st., in the general form of the body; 2nd., in the organ of locomotion; 3rd., in the nature, form, and position of the branchiæ; 4th., in the heart, and in the distribution of the circulating vessels; 5th., in the mouth and its veil; 6th., in the tongue and the rest of the digestive organs; 7th., in the position of the vent; and 8th., last, but not least, in the nervous system.

What, then, are the differences? 1st, the form of the shell composed of eight pieces instead of one; 2nd, the mantle, which is more fleshy and fibrous than in the other mollusks; 3rd, the myology; 4th, the double issue of the organs of generation, allowing this difference to be established, whereas it is doubted. With regard to the absence of eyes, that defect exists in a considerable number of mollusks.

Hence Deshayes concludes, and the conclusion appears to us to be just, that the chitons are true mollusks, and that their place is not far distant from the *Patellæ*.

Geographical distribution. The species are numerous, and there are few rocky shores without some of them. As a general rule, the largest are found in warm climates, but there are exceptions; for instance, *Chiton setiger* and *Chiton Bowenii*, King, are found on the shores of Tierra del Fuego, and in the straits of Magalhaens: the former of these species grows to the length of two inches and three-eighths, and the breadth of one inch and three-eighths, and the latter to the length of three inches and two-eighths, and the breadth of one inch and a half. No mention is made of them in the 'Supplement to Captain (now Sir Edward) Parry's Voyage' (1819—20), nor in the 'Supplement to Captain (now Sir John) Ross's Voyage' (1829—1833). The British species are small.

---

* Last edition of Lamarck, vol. vii., p. 487.

† The stomach is membranous, and the intestine is very long and much folded. The vent is situated under the posterior extremity

* Upon the rectum.

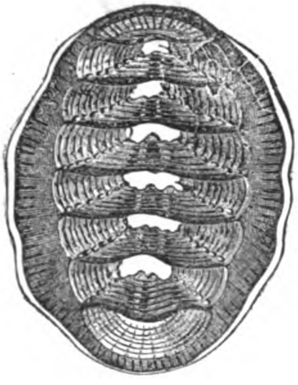
† Cuvier says that the ovary is situated above the other viscera, and that it would seem to open at the sides by two oviducts.

Locality. Rocky shores where it adheres, and also on stones and other submarine bodies. Found at depths varying from the surface to twenty-five fathoms.

Most zoologists are agreed that there are no differences sufficiently strongly marked to make a generic distinction between *Chiton* and *Chitonellus;* and, indeed, the gradations from the one to the other are so imperceptible, that there is no point where the line can be satisfactorily drawn. In the most completely-developed form of *Chiton* the shelly secretion greatly preponderates; in *Chitonellus* that secretion is comparatively small, and the great development is in the border of the mantle, which, in some instances, almost hides the comparatively-minute shelly pieces.

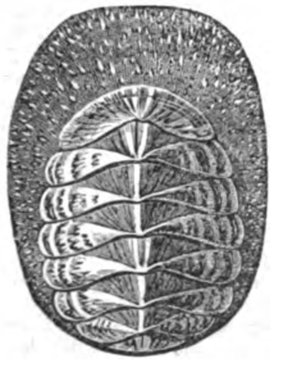
a. Species with the mantle border or marginal ligament, coriaceous and naked. Examples, *Chiton Chilensis,* Frembley, and *Chiton Blainvillii,* Broderip.

Chiton Chilensis. Shell oblong-ovate, opaque, thick, dark brown, smooth, dull; inside white, with pink markings on the first, second, and last valves. Valves with longitudinal *striæ,* crossed by irregular concentric ridges. Anterior and posterior valves semilunate, slightly punctated; second valve subcarinated, the front margin obtusely angled, lateral margins arcuate, and the posterior with a prominent beak, on each side of which diverges a rather elevated granulated ridge; the next five valves alike, bow-shaped, with a granulate ridge on each side. Border smooth, coriaceous, tough, thick, darker coloured than the shell, semipellucid, broad at the sides and narrow at the extremities. Locality, Valparaiso, in crevices of rocks and under stones. (Frembley.)



[Chiton Chilensis.]

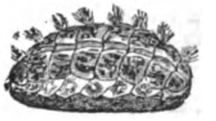
Chiton Blainvillii. In this species the shape of the coriaceous border itself is not only very remarkable, but it is here and there fringed, though not with hair. M. Deshayes has placed this under his section of those species which have the border of the mantle fringed with hair or spines, probably from not having seen a good specimen. *Shell* roundish, anterior valve obscurely rayed, the posterior one very small and abrupt; the others concentrically lineated, the whole being rosy, variegated with white, brown, and greenish and, internally, white. The mantle-border orange-red, very narrow posteriorly, and enormously produced anteriorly, rounded and fringed here and there, especially on its anterior margin, with some short coriaceous processes. Locality, Inner Lobos Island, coast of Peru.



[Chiton Blainvillii. Copied by permission from Sowerby's 'Illustrations of Conchology.'—Recent Shells.]

β. Mantle-border smooth, but with tufts of hair at the lateral extremities of each plate. Example, *Chiton Fascicularis,* Linnæus.

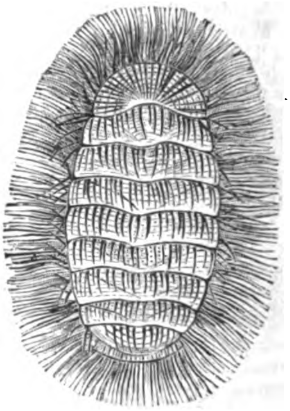
Shell apparently smooth, but when examined with a glass, proving to be rough like shagreen, except on the elevated dorsal ridge; margin surrounded with tufts of whitish hair, one at the junction of each valve, and two in the front, making eighteen in number. Colour brown or dark cinereous; length five-eighths of an inch; breadth rather more than two-eighths. Locality, British southern coasts. Montagu, who gives this description, says, that on the coast of Barbary it is not unfrequently an inch long.



[Chiton fascicularis.]

γ. Mantle-border hairy. Example, *Chiton Peruvianus,* Lamarck.

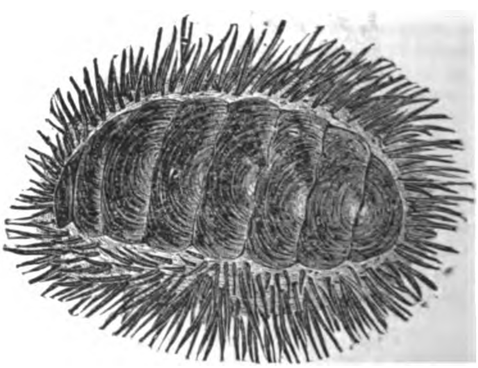
Shell oblong-ovate, opaque, dirty yellowish green, or yellowish brown, inside white. Valves thin, slightly elevated; posterior compartments of the dorsal valves a little raised and striated, with minute granulated striæ, and in like manner the other parts of the shell; under each valve is inserted a series of short black hairs, which lie on the back of the shell. Border narrow, coriaceous, thickly set with coarse black hairs. Length two inches, breadth one and a half. Found under stones at low water on the shores of Valparaiso Bay. There is a variety with the anterior valves much narrower than the posterior. (Frembley.)



[Chiton Peruvianus.]

δ. Mantle-border beset with spines. Example, *Chiton spinosus,* Bruguière; and *Chiton spiniferus,* Frembley.

Chiton spinosus. Shell brownish black, valves opaque,

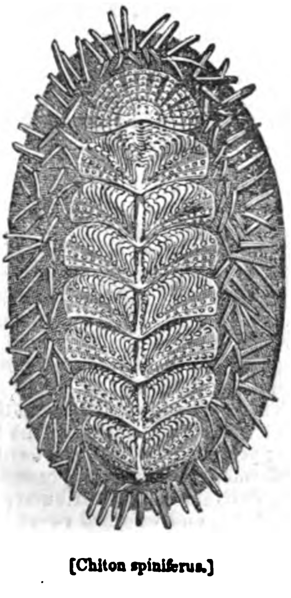


[Chiton spinosus.]

moderate, with the sides granulated, the anterior valves entirely granulated. Mantle-border wide, and beset with long aculeated blackish spines, very much resembling those of certain *Echini*. Locality, South Seas, according to Péron. Length three inches.

N.B. Lamarck describes the valves as smooth, and the specimen figured by Sowerby in his Genera has them nearly so. This may be the consequence of age and corrosion, for in a comparatively young specimen the sculpture of the valves is that above described. The species is very rare at present.

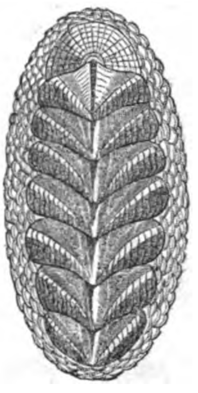
Chiton spiniferus. This is the *Chiton aculeatus* of Barnes, a name which had been preoccupied by Linnæus for another species, and the *Chiton tuberculiferus* of Sowerby in the 'Tankerville Catalogue;' but the latter name was given from an old specimen with broken spines, and has been rejected as inapplicable. Shell opaque, oblong ovate, reddish-brown, glossy; inside reddish-white. The posterior angles of the valves do not cover the anterior ones. Anterior valve with generally nine rows of raised dots diverging from the apex, but the number perhaps varies with the age of the shell. Second valve rather acutely beaked and carinated, longer than the five following, which are striated and shaped alike; these all rise into a rather acute beak, are carinated, each side of the carina being divided into two distinct portions, the anterior one the largest, and bearing broad, irregular, longitudinal striæ; a prominent row of raised dots, extending from the apex to the anterior angles of the valves, separates the compartments; the posterior portion glossy, with fine concentric striæ; the posterior margins with tooth-like granulations. Last valve striated, like the anterior compartments of the others, and rising into a rather prominent beak, leaning towards the posterior margin; from under the beak are raised dots, disposed in a similar manner to those on the anterior valve. Border coriaceous, thick, broad, rough, greenish or orange-coloured, and in the younger specimens thickly studded with blunt spines; but in the old shells the spines are short and scanty, and generally covered with corallines; the inner edge of the border, inserting itself under the posterior angles of the valves, has the appearance of being deeply separated. (Frembley.) This species grows to the length of five or six inches, but has then generally lost all its external beauty. We have seen many individuals in all the stages of growth, and have invariably found the spines of the aged ones covered with that calcareous matter which is so frequently found adhering to shells and submarine bodies, but we have never detected anything organic about that which was attached to the spines of this species. Locality, Chili and Valparaiso, where Mr. Frembley found several specimens in very exposed situations; so much so, that collecting them was attended with much difficulty, and not unfrequently with danger, from the violence of the sea breaking on the rocks to which they attach themselves very strongly. They are generally covered with sea-weed.



[Chiton spiniferus.]

ε. Mantle-border scaly. Example, *Chiton Coquimbensis*, Frembley.

Shell ovate, narrow, opaque, greenish-brown, shining; inside blackish: the anterior valves with numerous undulated, concentric ridges; the next rather acutely keeled; the five following alike: carina broad and smooth, on each side of which is a similar ridge diverging from the beaks, and forming with the carina a sagittate figure, and connected with it by several strongly marked ridges: from under the beaks, to the anterior angles of the valves, extend sharp, moniliform ridges, each side of which is coarsely striated longitudinally. Border thick, moderately broad, and covered with coarse, seed-like scales, which are attached laterally. Length three inches, breadth one and a half (Frembley). The description was taken from a young shell; for as the shell advances in age, the middle of the valves, which are very solid, becomes eroded and covered with adhesions, *Balani*, *Patellæ*, &c. Mr. Frembley says, that the only part of the coast where he found this species was the south side of Coquimbo Bay: their habits, he adds, are very similar to those of *Ch. spiniferus*, with the exception that they seem more gregarious.

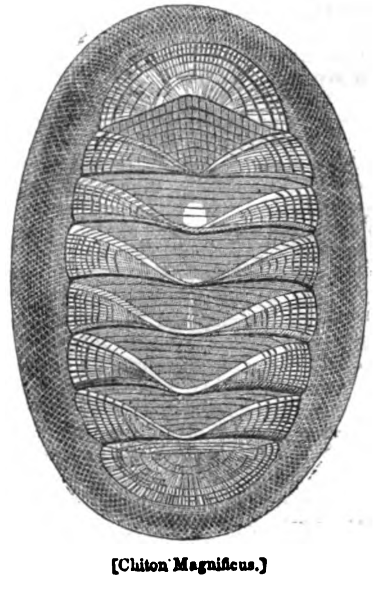


[Chiton Coquimbensis.]

ζ. Mantle-border granulous.

Example. *Chiton magnificus*, Deshayes.

Shell opaque, ovate, olivaceous, dull, dotted with lighter coloured spots: inside glaucous. The anterior valve with regular radiating striæ, crossed by concentric ridges; posterior margin nearly straight. Dorsal valves obtusely beaked, divided laterally into two compartments; the anterior having regular longitudinal striæ, crossed with others very minute and concentric; from under the beaks diverge to the lateral margins of the valves coarse and more irregular striæ, which raise the posterior compartment above the other. The posterior valve has a well-defined apex, leaning towards the posterior margin. Border thin, moderately broad, and covered with fine shining bead-like gra-



[Chiton Magnificus.]

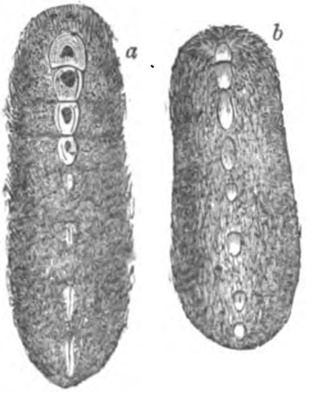
nulations, of the same colour as the shells, divided into two distinct portions, the upper of which is composed of finer beads than the lower, and which are placed transversely (Frembley). This is the *Chiton olivaceus* of Frembley, and *Chiton latus* of Sowerby (Tankerville Collection), which latter may be perhaps considered a variety, remarkable for its breadth. Deshayes had previously given to the species the name here assigned to it. The species grows to the length of four or five inches: we have seen one that reached four inches and a half when dead. There is another variety narrower than the ordinary individuals, and Mr. Frembley observes that, among the very young shells, some of them have their borders of a lighter colour than their shells, and spotted with black: this not being a constant character in all the young specimens, Mr. Frembley thinks they may be regarded as a variety. Locality, Chili.

*

Species with the border highly developed, and the valves very small. (*Chitonellus.*)

These are more or less cylindrical, and vermiform, the valves being very small, and in some species almost entirely hidden under the skin of the border, giving the animal an almost naked appearance.

Examples. *Chitonellus lævis*, and *Chitonellus larvæformis**.



a, Chitonellus lævis; *b*, Chitonellus larvæformis.

FOSSIL CHITONS.

G. B. Sowerby states that the fossil species are rare; and that detached valves are sometimes found in the calcareous sand of the neighbourhood of Paris and in the English crag. Deshayes in his tables (Lyell) gives but one fossil species (tertiary): in the 7th vol. of his edition of Lamarck (1836), he says that up to that time (jusqu'à présent) but one fossil species was known; and that was discovered at Grignon by M. Defrance. Since, he adds, the genus has been found in the transition rocks (le terrain de transition) in the neighbourhood of Tournay; and he states that the knowledge of this curious and interesting fact is due to the researches of M. Duchastel and M. Puzos.

The student should refer to the great work of Poli (Testacea utriusque Siciliæ), the Memoir of Cuvier in the Annales du Muséum, the article *Oscabrion* (by De Blainville) in the Dictionnaire des Sciences Naturelles, and in his Malacologie; and that by Deshayes in the Encyclopédie Méthodique. He should also consult the writings of Broderip, Bruguière, Frembley, Gray, King, Lamarck, Linnæus, Montagu, Pennant, Quoy and Gaimard, Rang, Sowerby, and Wood.

CHITONELLUS. [CHITON.]

CHITTAGONG, a district in the south-east part of the province of Bengal, bounded on the north by Tiperah district, on the east by the Burmese empire, on the south by the province of Aracan, and on the west by the bay of Bengal. This district lies between 21° and 23° north lat., and between 91° and 93° east long.; its length from north to south is about 120 miles, and its greatest breadth 50 miles, but the eastern boundary has never been accurately defined, and the average breadth is supposed to be not greater than 25 miles. According to an estimate made in 1784, the district was computed to contain 2987 square miles, about two-thirds of which were unproductive hilly country. The level lands lie near to the sea; the interior is generally hilly, and covered with jungle, the rapid growth of which is favoured by the moistness of the climate. The rainy season sets in earlier than in most other parts of the province of Bengal, and continues later, sometimes till the middle of November. The country is watered by numerous streams, one-half of which flow towards the bay of Bengal, and the rest into the Irawaddy. The most considerable of these streams is the Kamaphuli, or Chittagong river, which, at its mouth, forms a secure harbour, but so embayed, that during the continuance of the south-west monsoon it is generally difficult for vessels to put to sea. The channel of this river at the capital, Islamabad, is about a mile broad; but a little higher up its width does not exceed 200 yards, although the tide continues to flow strongly up the river. The source of this river is in Ava, whence it flows south-west to the district of Chittagong, which it enters by the Mugh mountains, where many waterfalls occur.

The river Nauf, which forms the southern boundary of the district, is about 70 miles south of Islamabad; it is not navigable: the banks of this river are, for the most part, covered with thick jungle, and exhibit only a few spots cleared for cultivation, and a few miserable dwellings of huntsmen, who catch and tame elephants, which are sent from Chittagong to every part of Hindustan. In the valley of the Kamaphuli are some rich tracts of land, cultivated by Bengalese, which yield plantains, ginger, betel-leaf, sugar-cane, cotton, indigo, and tobacco. The land is parcelled out into very small divisions, having formerly been assigned for the support of the military stationed in the district, to prevent the incursions of the Mughs of Aracan. When this military establishment ceased to be necessary the farms became zamindaries, and have been so considered in the administration of the country. Between the hills are several well-watered plains and valleys, of small extent, which are cultivated partly by Hindus of Bengal, and partly by Mughs of Aracan, who migrated into the district upon the conquest of their country by the Burmese in 1783. The majority of the Mughs who thus settled in Chittagong are traders and mechanics, only a small proportion having become cultivators. Exclusive of the Mugh settlers, the inhabitants of Chittagong were estimated, in 1801, at 1,200,000; but this number is probably excessive, considering the physical circumstances of the country. The Mohammedan inhabitants exceed the Hindus in number in the proportion of three to two.

It is supposed that Chittagong was once a frontier province, belonging to the independent kingdom of Tripura, and that during the conflicts between the Buddhists and Brahmins, it was governed sometimes by chiefs of one and sometimes of the other religion. During the wars between the Moguls and Afghans, the district was held by the Buddhists of Aracan, and yet at the beginning of the present century the population contained scarcely a single Buddhist. In 1582 this district was enumerated by Abul Fazl among the dominions of the Mogul sovereigns, yet it does not appear to have been actually in their possession until 1666. Nearly a century later (1760), Chittagong was ceded to the East India Company, by Jaffier Ali Khan. In 1826, when Aracan was taken from the Burmese, the political superintendence of Chittagong was included within the government of Aracan, and has so continued to the present time.

(*Ayin-i-Akbari*; Rennell's *Memoir*; Hamilton's *East India Gazetteer*; *Report of Committee of House of Commons* (1832) *on affairs of India.*)

CHITTOOR, a town and small pollam or district on the western side of the Carnatic, in 13° 15′ N. lat., and 79° 10′ E. long., eighty-two miles west from Madras. The situation is naturally strong, being between two ranges of hills, one of which bounds the Balaghaut, and the other forms an irregular sweep of various elevation, and approaches within a few miles of the sea at a short distance from Madras. This tract was acquired from the Nabob of the Carnatic in 1801, and an assessment of the lands was made in the following year; but it was not until 1804, that the British obtained complete and quiet possession through the expulsion of the Poligars, or small tributary chiefs by whom the lands were held, and who had never been thoroughly subdued by the Mohammedans. (Hamilton's *East India Gazetteer.*)

---

* Cuvier, in the last edition of the Règne Animal, has the following note to Chiton (Les Oscabrions). 'Les Oscabrelles (*Chitonellus*) de Lamarck et toutes les espèces de *Chiton* des auteurs doivent rester sous ce genre dont M. de Blainville a cru devoir faire une classe à part, qu'il nomme *Polyplaxiphores*, supposant qu'elle conduit aux animaux articulés.'

CHIVALRY has commonly been represented as a great institution, invented in the eleventh century, for a grand moral purpose—that of struggling against the deplorable condition of society at that period—of protecting the weak against the strong, and redressing individual injuries. So prevalent and so deeply-rooted has been this notion of the origin of Chivalry, that we find it set forth even in the new *Histoire des Français* of M. de Sismondi, a writer usually so clear-sighted and so little a slave to the routine of his predecessors. But a closely attentive as well as philosophical analysis of the history of European society, in the middle ages, proves this theory, or rather this supposition, to be deceitful. It shows us that Chivalry was not, in the eleventh century, an innovation, an institution brought about by a special exigency which it was expressly adapted to meet. It arose much more simply, more naturally, and more silently; it was but the development of material facts long before existing—the spontaneous result of the Germanic manners and the feudal relations. It took its birth in the interior of the feudal mansions, without any set purpose beyond that of declaring, first, the admission of the young man to the rank and occupation of the warrior; secondly, the tie which bound him to his feudal superior—his lord, who conferred upon him the arms of knighthood.

Of this we find an irrefragable proof in the history of the term *miles* itself, which was constantly used in the latinity of the middle ages to designate the chevalier, or knight. Towards the end of the Roman empire, the verb *militare* signified simply to serve, to discharge some service towards a superior, whether the service itself were of a military or a civil nature. The service originally denoted by this expression, indeed, was, no doubt, the military service exclusively; but the use of the term had in course of time been extended until it embraced every subordinate office and function. After the Germanic invasions of the declining Roman empire, we find it frequently employed in speaking of the household of the barbarian kings, and the offices which their companions held about their persons. Soon, by a natural retrogression, in conformity with the new turn given to the social state, the term *miles* resumed its almost exclusively warlike character, and denoted the companion, faithful to the service of his superior. It thus became synonymous with *vassus*, or *vassallus*, and indicated that a certain man held of another a beneficium, or fee, and was attached to him by that consideration; in short, from the ninth to the twelfth century, the word *miles* denoted, not the chevalier, or knight, as ordinarily conceived of, and as M. de Sismondi himself has described him, but simply the companion, the vassal, of a feudal superior.

Here we see the true and necessary origin of chivalry. But in the course of its development, when once the feudal society had acquired some degree of stability and self-confidence, the usages, the feelings, the circumstances of every kind, which attended the young man's admission among the vassal warriors, came under two influences which soon gave them a fresh direction, and impressed them with a novel character. Religion and imagination, poetry and the church, laid hold on chivalry, and used it as a powerful means of attaining the object they had in view, of meeting the moral wants which it was their business to provide for. So early as the ninth century we find some religious ceremonies associated with the Germanic practices on these occasions. A succinct account of the reception of a chevalier, as practised in the twelfth century, will show what progress this combination had made, and how powerfully the church had laid its grasp on every particular of that solemn act of the feudal life.

The young man, the squire, aspiring to knighthood, was first of all stripped of his garments and put into a bath, the symbol of purification. On his coming out of the bath, they clad him in a white tunic, the symbol of purity, a red robe, emblematic of the blood which he was to shed in the cause of the faith, and a black doublet, in token of the dissolution which awaited him as well as all mankind. Thus purified and clothed, the novice kept a rigorous fast for twenty-four hours. When evening came, he entered the church, and passed the night in prayer, sometimes alone, sometimes with a priest and with sponsors who prayed in company with him. The next morning, his first act was confession; after which the priest administered to him the communion; and after communion he heard a mass of the Holy Ghost, and commonly a sermon on the duties of a chevalier, and the new course of life on which he was about to enter. When the sermon was over, the novice advanced towards the altar, with the sword of knighthood suspended from his neck: the priest took it off, blessed it, and attached it to his neck again. The novice then went and knelt before the lord who was to knight him. 'To what end,' the lord then asked him, 'do you desire to enter into this order? If it is that you may be rich, repose yourself, and be honoured without doing honour to knighthood, then you are unworthy of it, and would be to the knighthood you should receive, what the simoniacal clergyman is to the prelacy.' And on the young man's answering that he promised well to discharge the duties of a knight, the lord granted his request.

Then did knights in attendance, and sometimes ladies, approach the novice, and array him in his novel garb, putting on first the spurs, next the hauberk or coat of mail, then the cuirass or breast-plate, then the brassarts or arm-pieces, and the gauntlets, and lastly girding on the sword Then, he was *dubbed*, to use the modern English expression derived from the French *adoubé*, which, according to Ducange, signified *adopted*. The lord rose from his seat, went up to him and gave him the *accolade*, that is, three strokes with the flat of his sword upon the shoulder or the nape of the neck, and sometimes a blow with the palm of his hand upon the cheek, saying, 'In the name of God, Saint Michael, and Saint George, I make thee a knight;' and sometimes adding, 'Be thou brave, bold, and loyal.' The young man being thus knighted, they handed him his helmet, and brought him a horse upon which he sprang, usually without the aid of the stirrup, and caracoled within the church, brandishing his lance and flourishing his sword Then quitting the church, he went and exhibited himself in like manner in public, beneath the castle walls, before the populace, whom he found eagerly awaiting their share of the spectacle.

It is easy to recognize in all this the influence of the priesthood, studious to associate religion with every circumstance of a solemnity so important in the warrior's life. Not only have the Christian sacraments their place in the ceremonial, but several of the observances more peculiarly chivalric are assimilated as much as possible to the administration of a sacrament. Such was the share taken by the ecclesiastical order in what may be called the exterior material part of the reception of a knight. And when we look into the moral character of chivalry, when we examine the series of oaths required of the knights at various periods from the eleventh to the fourteenth century, and mark the ideas and the feelings with which it was sought to imbue them, we find the clerical influence no less distinctly apparent. Certain it is, that in the obligations thus imposed upon the chevalier, we find a moral development extremely foreign to the state of lay society at that period. Moral notions so exalted—often so delicately scrupulous—above all, so humane, and so constantly impressed with the religious character, evidently emanated from the clergy. They alone then viewed the duties and relations of men in such a light; and their influence, it must be owned, was constantly employed in directing towards the fulfilment of those duties, and the improvement of those relations, the ideas and the usages to which chivalry had given birth. Whatever evils resulted from the unscrupulous and improvident use which the Roman church made of this direct influence over the power of the sword, in promoting so many crusades against the infidel and the schismatic, it undeniably made use of the chivalric institutions which feudalism had brought forth, in labouring to introduce internal peace in society, and a stricter and more comprehensive morality into individual conduct.

In proportion as this endeavour succeeded, and as chivalry more and more appeared under a character at once warlike, religious, and moral, at once conformable and superior to the actual manners, it seized upon and inflamed the imaginations of men; and in like manner as it had intimately bound itself up with their belief, so it also became the ideal standard of their aspirations, and the source of their most exalted pleasures. Poetry, in short, laid hold on chivalry, as religion had already done. As early as the eleventh century, the chivalric ceremonies, duties, and adventures, formed the mine to which the poets resorted for the means of charming the people; of at once gratifying and stimulating that craving of the imagination, that thirst for incidents more varied and more stirring, for emotions purer and more elevated, than real life affords. For it should be observed that in the earlier stages of society poetry is not merely a national pastime; it is also a means of progress, exalting and developing man's moral nature. The poetical remains that have descended to us from that age show, that the poet imposed upon the chevalier the fulfilment of the same duties, and the practice of the same virtues, as were inculcated in the more solemn exhortations of the priest.

It is an oft-repeated observation, that all this was mere poetry, a fine chimæra, bearing no resemblance whatever to the reality. And indeed, when we consider the state of manners in those three centuries, and the incidents of daily occurrence that filled the lives of men, the contrast between the duties and the actions of the chevaliers is truly shocking. The period before us is undoubtedly one of the most grossly brutal in the history of European society, one in which we find the greatest amount of crime and violence, in which the public peace was most incessantly disturbed, in which the most dissolute manners prevailed. To any one attending only to the positive and practical state of society, all this poetry and morality of chivalry looks like sheer falsehood. Yet it is undeniable that the chivalric morality and poetry existed simultaneously with these disorders, with this barbarism, with all this deplorable social state. The monuments are before us: the contrast, we repeat, is shocking, but it is real.

This very contrast, however, forms the great distinctive characteristic of the middle ages. When we look into other social systems, as the Greek and Roman, when we examine, for instance, the early stage of Greek society, its heroic age, of which the poems that bear the name of Homer present a faithful mirror, we there find nothing resembling the contradiction that strikes us in the middle ages. The practice and the theory of manners are there nearly accordant. We do not find men having ideas much purer, nobler, and more generous than their daily acts. Homer's heroes seem quite unconscious of their own brutality, ferocity, selfishness, and covetousness; their moral science is no better than their conduct; their principles are on a level with their acts. We find it to have been the same with all other social systems in their vigorous and turbulent youth. But in Europe, on the contrary, in the middle ages, while the deeds are habitually detestable, while crimes and disorders of every description abound, yet we find dwelling in the minds and imaginations of men nobler instincts and more exalted aspirations. Their notions of virtue are much more developed; their ideas of justice incomparably better than what is practised around them, than what they practise themselves. A brighter ideal of morality hovers, as it were, above that rude and stormy social state, attracting the view and commanding the respect of men whose lives are little conformable to it. Christianity must undoubtedly be ranked among the principal causes of this fact: for its great characteristic is, its labouring to inspire men with a high moral ambition, to keep constantly before their eyes a standard infinitely superior to human reality, and stimulate them to attain it. But whatever be the cause, the fact is indubitable. We find it everywhere in the middle ages, in the popular poetry as well as in the exhortations of the priests. The moral conceptions of men rose far above the practice of their lives. Nor let it be thought, because those conceptions did not govern their actions, because their practice so strangely belied their theory, that the influence of the theory was absolutely null. The habitual judgment of men upon human actions is not without its effect. It has been justly remarked, that a bad action is better than a bad principle: a bad action may remain isolated and solitary; but a bad principle is constantly fructifying: for, after all, it is the mind that governs; and a man acts from reflection much oftener than he is himself aware of. In the ages of chivalry, we repeat, the principles were infinitely better than the acts. For instance, at no period perhaps has the intercourse between the sexes been more licentious; yet never was purity of manners more strongly enjoined or more feelingly described. Nor was it a theme for poetic eulogy alone. We find from a multitude of testimonies that the public thought in this particular as the poet spoke, that the prevailing moral notions were pure and noble amidst all the rudeness and licentiousness of conduct.

This, then, was the grand moral characteristic of chivalry, which entitles it to an important place in the history of modern civilization. If, on the other hand, we regard it not in a moral but in a social point of view, not as an idea, but as an institution, it merits but slight consideration; for though it had a great and stirring part in the world's affairs, yet, as already shown, it did not constitute an actual specific institution at all. The feudal lords, the possessors of fiefs, were alone chevaliers; they alone, with few exceptions, had the right to become so. The knights formed no separate class of society with distinct functions and duties. Thus chivalry, properly so called, being inseparably bound up with feudality, could not survive its extinction; and accordingly, so early as the fourteenth century, when compared with its condition in the twelfth, we find it to be rapidly declining.

It had, however, given birth to the religious orders, as the Templars, the knights of St. John, and the Teutonic knights; and it was beginning to produce the courtly orders—those of garters and ribbons—the knighthood of mere rank and parade. It was destined to tincture yet a long while the manners, the language, and the literature of European society. But the true chivalry, that to which alone the name can strictly be applied, flourished and fell with feudalism.

CHIVES, a small species of allium called ampeloprasum. Its bulbs have the usual garlic odour of the genus, and are used in soups and stews: they are but little cultivated.

CHLÆ'NIUS, a genus of coleopterous insects, of the family *Harpalidæ*, and section *Patellimmanes* (Dejean.)

The species of this genus are all of tolerably large size, very elegant in form, and generally adorned with various hues of green, the colours being rich, but not glossy, owing to the upper parts being more or less covered with a very delicate pubescence, which produces a silk-like appearance. Very many of the species have the legs and antennæ of a pale yellow colour, and the outer margin of the wing-cases of the same tint, and some have the elytra adorned with large yellow spots.

The genus Chlænius constitutes a very large group of the Harpalidæ, which, according to our views, embraces the genera *Epomis* and *Dinodes*, we will therefore briefly notice the distinguishing characters of these three groups.

All three of the genera agree in having the tarsi of the anterior pair of legs dilated in the males, and a bifid tooth in the middle of the emargination of the mentum; but they differ chiefly in the form of the terminal joint of the palpi, and the difference may be thus expressed:—

Terminal joint of the palpi.
Elongated and truncated at the apex, *Chlænius*.
Elongated and distinctly securiform *, *Epomis*.
Short and slightly securiform, *Dinodes*.

As regards the form of these insects, the body is generally more or less oval, and very slightly convex: the thorax is almost always considerably narrower than the elytra, broad towards the anterior part, and diminishing in width towards the posterior. The head is rather long, the eyes project considerably, and are rather remote from the base of the head, the portion of the head before the eyes is rather pointed.

The species are found under stones, weeds, and almost any rubbish which will afford them shelter; sometimes under the loose bark of old trees, near the root, but they must be sought after in the vicinity of water.

Of the genus Chlænius M. Le Comte Dejean enumerates one hundred and fifteen species, a great portion of which are European; many are from Africa, the East Indies, and North America, but South America and Australia appear to be almost destitute of these insects.

In England eight species have been discovered; of these however two only have been found in any abundance. *Chlænius vestitus* (*Carabus marginatus*, Lin.) is very common in the south of England, and is found under stones by the edges of ponds where gravel abounds. It is nearly half an inch in length, black beneath, and of a rich green colour above: the elytra are distinctly striated, very finely punctured, and covered with a delicate pubescence of a golden hue: their outer margin is of a pale yellow colour: this tint is confined to a narrow line towards the base of the elytra, but forms a broad patch at the apex; the head and thorax are rather glossy; the latter is finely punctured throughout, and has the margin slightly tinted with yellow; the legs, antennæ, and palpi are yellowish-white when the insect is alive.

---

* Securiform (*securiformis*). 'When the last joint of the feeler is triangular, and the preceding joint is connected with the vertex of the triangle.' Kirby and Spence's *Introduction to Entomology*, vol. IV., p. [illegible]

Of the genus *Epomis* M. Dejean enumerates six species, one of which is said to have been found in England, but it is here decidedly very rare, since only three specimens are recorded. It is about three-quarters of an inch in length; the head and thorax are of an obscure brassy-green colour and slightly punctured; the elytra are black, with the outer margin pale yellow; the legs and antennæ are also yellow.

This species is not uncommon in France and Italy.

The genus *Dinodes* only embraces four species. *D. rufipes* is about half an inch in length, of a rich blue colour above, and finely punctured throughout: the legs and base of the antennæ are of a reddish-yellow colour.

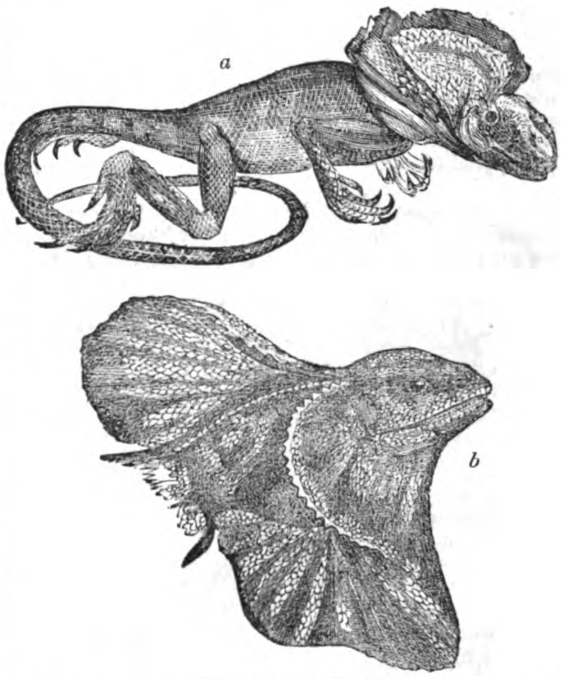
The thorax in this genus (taking *D. rufipes* as the type) is broader and more rounded than in the genera Chlænius and Epomis. The species described is found in France and Italy.

CHLAMYDOSAURUS, a genus of Saurians, founded by Mr. Gray, upon a specimen brought home by Captain Phillip Parker King, R.N., F.R.S., &c., on his return from his survey of the intertropical and western coasts of Australia, performed between the years 1818 and 1822. The following is Mr. Gray's description:—

Animal scaly; the head depressed; the nostrils placed on the side, midway between the eyes and the end of the head; the drum of the ear naked; the front teeth conical, awl-shaped (eight in the upper, and four in the lower jaw), the hinder ones longest; the side or cheek teeth compressed, short, forming a single ridge, gradually longer behind; tongue short, fleshy, with an oval smooth disk at each side of the lower part of its front part; neck rather long, furnished on each side with a large plaited frill, supported above by a crescent-shaped cartilage, arising from the upper hinder part of the ear, and, in the middle, by an elongation of the side fork of the bone of the tongue; body compressed, legs rather long, especially the hinder ones; destitute of femoral pores; feet four, with five toes, the first having two, the second three, the third four, the fourth five, and the little finger and toe three joints; claws compressed, hooked; tail long, nearly round, scaly. Example, *Chlamydosaurus Kingii.* The colour is yellowish-brown, variegated with black. The head is depressed, with the sides erect, leaving a blunt ridge on the upper part wherein the eyes are placed. The ridge over the eyes is covered with larger scales than those over the head. The eyes are rather small, with a fleshy ridge above them, and the eyelids are covered with minute scales, and surrounded by a delicate serrated ridge of small upright ones. The lips are surrounded by a row of oblong four-sided scales, arranged lengthways, the front scale of the upper lip being the largest. The chin is covered with narrow mid-ribbed scales, with a five-sided one in the centre, and several of larger size just over the front of the fork of the lower jaw. The nostrils are surrounded by a rather large orbicular scale, situated nearly mid-way between the eye and the end of the upper jaw, the tubes pointing forwards. The side of the face has a very obscure ridge extending from the angle of the mouth to the under part of the ear. The neck is covered with small scales. The frill arises from the hinder part of the head, just over the front of the ears, is attached to the sides of the neck, and extends down to the front part of the chest, supported above by a lunate cartilage arising from the hinder dorsal part of the ear, and in the centre by a bone which extends about half its length. Each frill has four plaits which converge on the under part of the chin, and fold it up on the side, and a fifth where the two are united in the centre of the lower part of the neck. The front part of its upper edge is elegantly serrated, but the hinder or lower part is quite entire: the outer surface is covered with carinated scales, those in the centre being the largest. The inner surface is quite smooth. The scales of the back are oval, and nearly smooth; those of the lower part of the body and upper part of the legs have a short mid-rib, and those of the sides and joints of the limbs are minute. The tail is twice as long as the body, roundish, covered with scales which have each a sharp mid-rib, and towards the termination, which is blunt, form six rows, so as to render that organ obscurely hexagonal. The toes are long, very unequal, compressed, and scaly. The claws are hooked, and horn-coloured.

Dimensions. Length of the tail, twelve inches; of the body, five; of the head, five and a-half. Breadth of the head over the eyes, one inch. Length of the thigh, one inch nine-tenths; of the foot and sole, two inches two-tenths; of the outer edge of the frill, ten inches.

Locality and *Habits.* We owe the discovery of this extraordinary Saurian to Mr. Allan Cunningham, who accompanied Capt. King's expedition as his Majesty's botanical collector for Kew Gardens, and to whom naturalists in general are so much indebted for the zeal displayed by him in favour of natural history, and for the liberality with which he has communicated the results of his labours. He found the specimen from which the description was taken on the branch of a tree in Careening Bay, at the bottom of Port Nelson, and sent it to Sir Everard Home, by whom it was deposited in the Museum of the Royal College of Surgeons. The following is the account of the capture in Mr. Cunningham's Journal:—'I secured a lizard of extraordinary appearance, which had perched itself upon the stem of a small decayed tree; it had a curious crenated membrane, like a ruff or tippet round its neck, covering its shoulders, and when expanded, which it was enabled to do by means of transverse slender cartilages, it spreads five inches in the form of an open umbrella. I regret that my eagerness to secure so interesting an animal did not admit of sufficient time to allow the lizard by its alarm or irritability to show how far it depended upon, or what use it made of, this extraordinary membrane when its life was threatened. Its head was rather large, and eyes, whilst living, rather prominent; its tongue, although bifid, was short and thick, and appeared to be tubular.' According to Captain King, the colour of the tongue and inside of the mouth was yellow. Mr. Gray is of opinion that this genus is nearly allied to the *Agamæ*. [AGAMA, Zoology.] We give a representation of the dead animal from the figure in the Appendix to Captain King's 'Voyage,' where the animal and its capture are described; and, below it, a representation of the living head, as it is seen in the illustrations to the 'Suites à Buffon.'

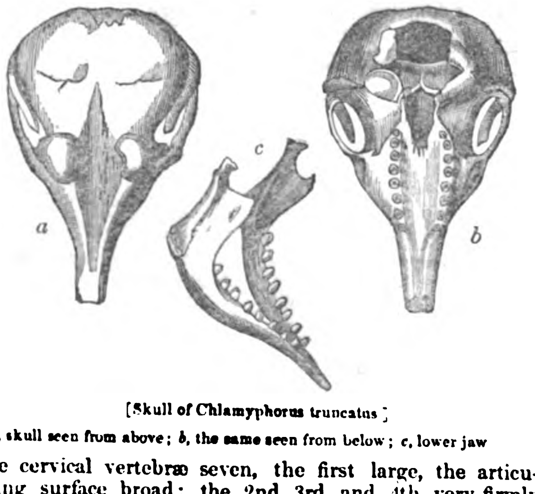


[Chlamydosaurus Kingii.]

a, the animal in the Museum of the College of Surgeons; *b*, representation of the living head.

CHLAMY'PHORUS (Zoology), Dr. Harlan's name for a genus of quadrupeds, of the order *Edentata*, first described by him in the 'Annals of the New York Lyceum of Natural History,' vol. i., from a specimen presented to the Philadelphia Museum, on the 18th December, 1824, by Mr. William Closeberry, according to whom it is the *Pichiciago* of the Indians in Mendoza (its native place), on the east of the Cordilleras, in lat. 33° 25′, and long. 69° 47′. It had been obtained on the spot in a living state, but lived in confinement only a few days. The viscera and the greater portion of the skeleton had been removed before the animal came into Dr. Harlan's possession. In March, 1828, the council of the Zoological Society of London, influenced by the recommendation of Mr. Vigors, placed in the hands of Mr. Yarrell a specimen of this rare and new animal, and the latter able zoologist so executed the trust reposed in him, as to produce a perfect skeleton, without injuring the skin, which was mounted by Mr. Leadbeater. When Mr. Yarrell returned the specimen to the Society, he accompanied it with a valuable paper on the osteology of the animal, from which we are enabled to supply the information which the absence of materials prevented Dr. Harlan from giving.

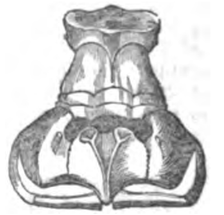
Osteology. The form of the head presents the figure of an irregular cone, the base of which is turned toward the spine; the cranium does not exhibit any sutures; the cavity capacious; the frontal bone supporting two rounded processes projecting upwards and somewhat outwards; the space between them occupied by a substance resembling in appearance adipose matter, from which issued a fluid-like oil. From the anterior part of the base of these two rounded processes, a narrow ridge of bone extends forwards on each side converging towards the nose. The nasal bones elongated, the orifice opening downwards. No incisor nor canine teeth in either jaw; molars $\frac{8}{8}$, cylindrical, separate, encircled with enamel, but none on the crowns; the first tooth on each side in the lower jaw, having no opponent, is the longest, the remaining seven opposed to the first seven of the upper jaw, and taking angular impressions on their surfaces by contact; the direction and depth of the alveolar cavities of the upper jaw distinctly marked on the outside by parallel ridges; in the lower jaw the alveolar cavities are pierced the whole depth. The anterior portion of the lower jaw is elongated; the inferior edge concave the first half of its length, then convex; the plate broad, rising at right angles with the line of the teeth; the condyloid process longer than the coronoid, the condyle itself elongated transversely. The external meatus auditorius is extended in the form of a semicircular cylindrical tube of bone, curving round the base of the zygoma, and passing forwards terminates in an aperture immediately behind the eye. The orbits and temporal fossæ united; the zygomatic arch is slender posteriorly, but becomes much stronger towards the front, expanding downwards, and furnished with an acute descending process. The occipital foramen is of great size.



[Skull of Chlamyphorus truncatus]

a, skull seen from above; b, the same seen from below; c, lower jaw

The cervical vertebræ seven, the first large, the articulating surface broad; the 2nd, 3rd, and 4th, very firmly ossified together, pierced with foramina for the passage of the cervical vessels; the 5th united to the 4th on the under surface only; the 6th and 7th slender and separate, allowing the head great freedom of motion upwards; the whole of the last six grooved on the under surface, in the line of the passage of the œsophagus. Dorsal vertebræ eleven, the spinous process of the first slender, three-eighths of an inch long, the others diminish gradually in length, but increase in size; all directed backwards. The first rib is very broad, and from the 2nd to the 8th, the ribs of the *Chlamyphorus*, like those of birds, are firmly united to the sternum without the intervention of an elongated cartilage; and, again like those of birds, are also supplied with a false joint, at the distance of about two-thirds of their length from the spine to the sternum The 9th, 10th, and 11th, being false ribs, are united in the usual way to each other, and to the 8th, by elongations of cartilage from their extremities. The portions of ribs intervening between the false joints and the sternum are in the 6th, 7th, and 8th ribs, consolidated, broad, flattened portions of bone, which form the boundary of the anterior and lateral parietes of the thorax. The first bone of the sternum is broad and flat, the superior surface regularly concave, the inferior irregularly convex. Upon the anterior edge of the sternum are two prominences, to which are attached the extremities of each clavicle. From each of these articulations a slightly elevated ridge proceeds backwards along the inferior surface of the sternum, converging towards the centre, where they become united, and form a prominent crest. The lateral edges of this first bone of the sternum are articulated at its anterior extremity to the first and broadest rib; from this part the bone suddenly becomes narrowed posteriorly, and terminates in a concave articular surface to which the second bone of the sternum is attached. Judging from the imperfect remains of the second bone, of which the upper part only was distinguishable, it would appear that its form was oblong, the superior surface concave. The remaining portion of the sternum was too much mutilated to admit further description.



[Cervical vertebræ, first bone of the sternum, with parts of the first and second ribs, seen from below.]

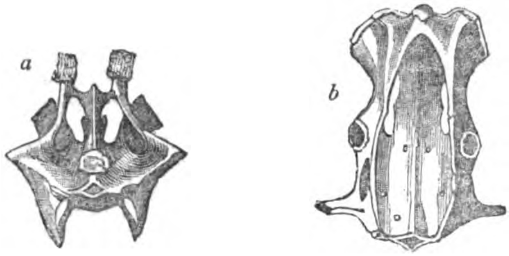
Lumbar vertebræ three, the spinous processes short and flattened; the two last dorsal vertebræ, as well as the lumbar, furnished with long oblique processes directed forwards, upwards, and outwards; the transverse processes of the first two lumbar vertebræ considerably elongated, the last possessing a rudiment only.

The whole of the sacrum and innominata is so peculiar and unique in character, that it is scarcely possible to give any correct idea of this part, without the assistance of accurate representations. The superior part of the ilium is flattened, the upper part bent to form an arched plane of bone, the concavity of which faces downwards and outwards; the crista of great length from before backwards. The inferior portion of the ilium is much stronger, inclining outwards, from its junction with the sacrum to the acetabulum.

The transverse and spinous processes of the sacrum are represented by three slender plates of bone, which, approximating as they pass backwards, are united to form a septum, extending down the median line of the sacrum to the tail. A channel is formed on each side of this septum by a thin flat plate of bone, which, arising from the posterior and superior part of the ischium on each side, is bent over the back part of the sacrum, and fixed to an arched and prominent plate of bone, which is extended from this septum outwards, to form a junction with it. The channels thus produced are bounded below by the sacrum, on the inner sides by the septum, on the outer sides by the ascending plates of bone just described, and above by the junction of both. From this union a short osseous stem issues horizontally on each side, and expands into a flattened circular plate of bone, to the rough surface of which, as well as to the tuberosity of the ischium below, portions of the truncated exterior of the animal are firmly attached.

The under surface of the sacrum is broad and flattened, and marked by an indistinct central ridge. The pelvis is open in front, the ossa pubis on each side do not incline inwards, but descend at right angles from the horizontal surface of the sacrum. In the circumstance of the pelvis being open, there is a second resemblance to the bony structure in birds.

The caudal vertebræ are fourteen in number; the transverse processes of the last four are elongated, to support the thin dilated lateral edges of the paddle or spatular extremity of the tail. Large muscles are imbedded in the two cavities formed on the upper surface of the sacrum by its septum and the two lateral elevated portions of the ischium before described; and there are antagonist muscles of equal size on the under surface. The tendons of these muscles were inserted on the upper and under parts of the caudal vertebræ, giving great power to the tail, which is probably exercised in removing backwards the loose earth accumulated under the belly of this burrowing animal by the action of the fore legs, and for which purpose the expanded and flattened extremity seems well calculated.

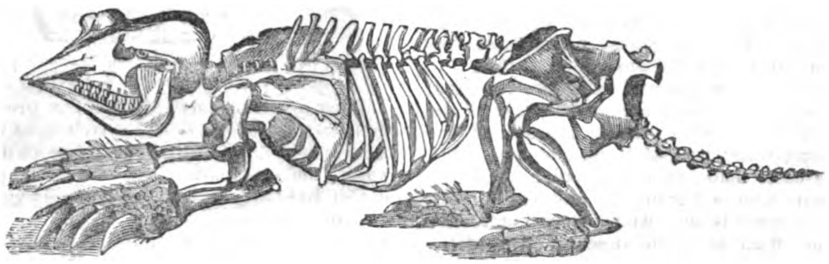


a, the pelvis seen from behind; *b*, the same seen from below.

[Vertebræ of the tail.]

The scapula has its superior margin straight, ending in a notch of great size; the base rounded; the inferior margin concave, and the posterior inferior angle considerably elongated; the coracoid process but little produced, the spine elevated, the acromion very long, passing forwards, downwards, and inwards, over the head of the humerus, to be articulated to a long and slender, but perfect clavicle. There is a second spine of smaller size, parallel to, but beneath the true spine. The humerus is three-fourths of an inch in length, large, and broad; the deltoid crest prominent; between which and the external condyle a deep groove is formed for the lodgment of muscles, &c.; both condyles very much elongated transversely; the inner condyle perforated above; the edge rising from the external condyle acute. The radius small, and seven-sixteenths of an inch in length; the ulna flattened, concave upwards, the olecranon nearly as long as the ulna, horizontally flattened also, and presenting a superior concave surface, ending in a curve pointing downwards. The feet furnished with sesamoid bones for the insertion of the tendons of the flexor muscles.

The femur, thirteen-sixteenths of an inch long, large and strong; the length of the neck considerable; the great trochanter elongated backwards beyond the line of the articulation of the head of the femur with the acetabulum, and ending in a tuberosity; the lesser trochanter directed downwards; a third trochanter projecting from the outer side of the shaft of the femur somewhat above the middle; the condyles moderately elongated transversely, the outer having a crest directed backwards. The tibia and fibula fifteen-sixteenths of an inch, flattened, concave inwards, firmly anchylosed at each extremity, and arched in opposite directions, giving an appearance of great size and strength to the leg. The os calcis elongated backwards, flat, and ending in a curve slightly inclined upwards. Hind feet plantigrade.



[Skeleton of Chlamyphorus truncatus, with the exception of the feet, which are covered with the integuments.]

Mr. Yarrell observed the following points of resemblance between the skeleton of *Chlamyphorus* and that of other quadrupeds:—1. Beaver (*Castor Fiber*), in the form and substance of some of the bones of the limbs, in the flattened and dilated extremity of the tail, and the elongation of the transverse processes of the lower caudal vertebræ, but no further. 2. Mole (*Talpa Europæa*), in the shortness and great strength of the legs, and in the articulation of the claws to the first phalanges of the toes; but in the form of the bones of the anterior extremity, as well as in the compressed claws, it is perfectly different, nor do the articulations of the bones, nor the arrangement of the muscles, allow any of the lateral motion so conspicuous in the mole. The hinder extremities of *Chlamyphorus* are also much more powerful. 3. Sloth (*Bradypus tridactylus*), in the form of the teeth, and in the acute descending process of the zygoma, but not otherwise. 4. Armadilloes (*Dasypi*), in the coat of mail, in the peculiar ossification of the cervical vertebræ, in possessing the sesamoid bones of the feet, and in the general form of the bones, except those of the pelvis; they differ however in the form and appendages of the head and in the tail. 5. *Orycteropus Capensis* and *Myrmecophaga jubata*, in some of the bones. 6. *Echidna* and *Ornithorhynchus*, in the form of the first bone of the sternum, and in the bony articulations as well as the dilated connecting plates of the true and false ribs. 7 and 8. *Ruminantia* and *Pachydermata*, in the form of the lower jaw, and in other points equally obvious. The unique points in its structure appear to be the form of the head and the open pelvis.

Dr. Buckland (Bridgewater Treatise) considers *Chlamyphorus* one of the nearest approximations to *Megatherium*, particularly in regard to its coat of mail, and in the adaptation of the animal for digging.

According to Dr. Harlan, the total length of the entire animal is five inches two-eighths. The *shell* which covers the body is of a consistence somewhat more dense and inflexible than sole leather of equal thickness, and is composed of a series of plates of a square, rhomboidal, or cubical form, each row separated by an epidermal or membranous production, which is reflected above and beneath, over the plates: the rows include from fifteen to twenty-two plates, the shell being broadest at its posterior half, extending about one-half round the body. This covering is loose throughout, excepting along the spine of the back and top of the head, being attached to the back immediately above the spine by a loose cuticular production, and by the two remarkable bony processes on the top of the *os frontis*, by means of two large plates, which are nearly incorporated with the bone beneath; but for this attachment the covering would be very easily detached. The number of rows of plates on the back, counting from the vertex, where they commence, is twenty-four; at the twenty-fourth the shell curves suddenly downwards, so as to form a right angle with the body: this truncated surface is composed of plates, nearly similar to those of the back; they are disposed in semicircular rows, five in number the lower margin, somewhat elliptical, presents a notch in its centre, in which is attached the free portion of tail, which makes an abrupt curvature, and runs beneath the belly parallel to the axis of the body, the extremity of the tail being depressed, so as to form a paddle; the rest of the tail compressed. The superior semicircular margin of the truncated surface, together with the lateral margins of the shell, are beautifully fringed with silky hair.

Head.—Posterior half, broad, anterior half, before the eyes, tapering; the occiput is covered by the five first rows of the back plates with which they are continuous; the occiput not distinguishable externally. The anterior half of the top of the head is covered, first, by a row of large plates, five in number, which are firmly attached to the bone beneath, particularly the two outer; secondly, by a smaller row, six in number, anterior to which, that is to say, the top of the snout, is covered with smaller plates irregularly disposed.

Mr. Yarrell observes that when separating the skin from the muscles of the back, the fibres (described by Dr. Harlan) by which the outer coat was attached in the line of the vertebræ were found to be adherent to the muscles immediately investing the spinous processes, and each of them, Mr. Yarrell supposes, probably affords a nidus for vessels nourishing the external covering; but these attachments did not extend below the dorsal vertebræ. Proceeding from thence forwards, the great size of the muscles of the scapulæ and neck was apparent, filling up the whole space, the back and upper portion of the head forming one continued line. The thick plate of scales covering the frontal portion of the head was without difficulty separated from the surfaces of the singular bony processes of the os frontis; the projecting cartilaginous portion of the nose was removed with the skin, and the tendons of several muscles giving motion to the snout were cut through.

The hinder portion of the body still remained to be separated from the skin, and this was found to be a matter of some difficulty. The posterior and inferior portions of the sacrum on each side were firmly united by distinct attachments, differing in form, to certain scales of the truncated extremity of the outer covering.

The necessity of preserving this outer covering entire rendered a division of these portions of bone necessary, and from the particular form of the part, this was attended with some hazard, but was ultimately accomplished without injury, the bones being cut through as near to, and as parallel with, the inner surface of the plates, as their confined situation would admit. The covering of the tail was separated from the vertebræ as far as the flattened extremity, where the greater elongation of the transverse processes of the last four vertebræ, and the tenuity of this flattened portion, made further separation difficult. The tail was then divided between the tenth and eleventh vertebræ, and both parts of the animal entirely separated.

On the inner surface of the removed skin were two long, broad, and thin muscles, extending the whole length of the back; each muscle was divided, as it approached the shoulder, into two portions; the outer one was attached to the superior and greater spine of the scapular bone, the inner and longer slip proceeded forwards, and was inserted into the transverse occipital ridge. The posterior extremity of each muscle was attached to the superior edge of the spine of the ilium.

External Ear.—This, according to Dr. Harlan, consists of a circular, somewhat patulous opening, directly posterior to the eye, surrounded with an elevated margin, and communicating with a bony canal.

Eye.—Minute, totally black; and, like the ear, nearly hidden by long silky hair.

Mouth.—Gape small.

Nose.—Furnished with an enlarged cartilage, as in the hog; the anterior nares opening downwards at the inferior border.

The whole surface of the body is, it appears from the same author, and the correctness of his description is proved by an inspection of the stuffed specimen, covered with fine silk-like hair, longer and finer than that of the mole, but not so thick set. The anterior of the chest is large, full, and strong; the anterior extremities short, clumsy, and powerful; the hair is continued for some distance on the palm—the phalanges of the hand united; five powerful nails rising gradually one above the other; the external shortest and broadest; the whole so arranged as to form a sharp cutting instrument, rather scooped, very convenient for progression under ground, and such as must very much impede motion on the surface. Hind legs weak and short; feet long and narrow; the sole resembles considerably the human foot, having a well defined heel, which rests flat upon the ground, and being arched in the middle, toes separate, nails strong.

In the specimen dissected by Mr. Yarrell, the abdomen and thorax had been opened throughout their whole length, and the viscera from both cavities had been entirely removed. Adhering to the skin lining the truncated portion of the animal, were two sacs which had been lodged in cavities on each outer side of the sacrum, immediately under the superior projection, made evident by the corresponding depression in the investing muscle of that part. These globular bags were lined with a secreting surface, but having suffered some mutilation in removal, the mode by which the secretion passed, or its particular use, could not be ascertained. Mr. Yarrell thinks that they are probably analogous to the well-known anal glands of various other quadrupeds.

Sexual Organs.—The sex, in the specimen dissected by Mr. Yarrell, was evident from the penis remaining attached to one edge of the divided abdominal muscles; and, lying quite loose in the cavity of the abdomen, was found one of the testes, but whether its original situation had been internal or external to the parietes, could not be ascertained. The penis itself was large compared to the size of the animal, and one inch and one-eighth in length. The confined situation of the female sexual organ, in Mr. Yarrell's opinion, probably renders such a provision necessary, the truncated portion of the coat of mail covering the whole of the posterior extremity.

We must refer the reader for further particulars to the papers of Dr. Harlan and Mr. Yarrell, both of which are to be found in the 'Zoological Journal' (vols. ii. and iii.)

Habits. According to Mr. Closeberry the habits of *chlamyphorus* resemble those of the mole, as it lives for the most part under ground. He adds that the animal is reputed to carry its young beneath the scaly cloak with which it is covered, and that the tail possessed little or no motion. The carrying the young in the manner described may be considered apocryphal till further evidence is obtained.*

CHLAMYS. [Chrysomelidæ.]

CHLEN'ACEÆ, a natural order of polypetalous exogens, by some accounted an ally of Malvaceæ, but more correctly referred to the vicinity of Cistaceæ, from which, and all those associated with them in the Gynobasic group, they differ in having an involucrum to each calyx, or to each pair of calices: they are handsome trees or shrubs, but of no known use; their leaves are alternate and undivided, their stipules deciduous, and their flowers in panicles or racemes, always showy, and often red. The whole of them are wild in Madagascar.

CHLOEIA. [Dorsibranchiata.]

CHLORAL, a liquid prepared by Liebig with chlorine and alcohol, from the first syllables of which words its name is derived. To form it, a current of dry chlorine gas is passed into anhydrous alcohol, at first kept cool, but afterwards sufficiently heated to expel the hydrochloric acid formed. During the action of these substances one portion of the chlorine unites with the hydrogen of the alcohol to form hydrochloric acid, and another portion with its oxygen and carbon to constitute chloral. When the operation has been long continued, a liquid of the consistence of a syrup is procured, which afterwards becomes solid; it is a hydrate of chloral containing some undecomposed alcohol and a portion of hydrochloric acid. It is then to be shaken with concentrated sulphuric acid, which combines with the water, and the chloral rises in a fluid state to the surface; this is to be mixed with lime, and by distillation the chloral is obtained free from hydrochloric acid.

Chloral is a colourless transparent oily-looking fluid; its smell is pungent, and its taste but slight; its specific gravity is 1·502; at about 200° Fahrenheit it boils, and the vapour condenses unchanged. Water when warmed dissolves chloral, but when mixed with a small quantity of it, they combine, when agitated, into a solid crystalline hydrate. It combines with bromine, iodine, and sulphur; when its vapour is passed over lime heated to 212°, it is decomposed, oxide of carbon is evolved, and chloride of calcium, mixed with a little charcoal, remains; by solution of potash or soda it is also decomposed, and a chloride of carbon is formed.

Chloral consists of

Six equivalents of	chlorine	36 × 6 =	216

CHLORANTHA'CEÆ, a natural order of achlamydeous exogens, allied to the Peppers, and, like them, having an aromatic fragrant odour; they are known from the orders associated with them by their jointed stems and opposite leaves, with intermediate stipules. Their flowers grow in naked spikes, and consist of an ovary next the axis of inflorescence, and a fleshy anther on the outside. Chloranthus officinalis is reckoned a stimulant of the highest order.

CHLORIC ACID. [Chlorine.]

CHLORIDES OF CARBON. [Chlorine.]

CHLORINE, an elementary gaseous body discovered by Scheele in 1774, while examining an ore of manganese. He gave it the name of dephlogisticated marine acid. By the French chemists, in accordance with the views of Berthollet, it was called oxygenized muriatic acid, which was shortened by the English chemists to oxymuriatic acid: these latter terms meant that it was a compound of muriatic acid, a supposed elementary or at any rate an undecomposed body, and oxygen. Gay-Lussac and Thénard in 1809 published some experiments from which they inferred that oxymuriatic acid might be a simple substance, but they notwithstanding adhered for a considerable period to the opinion of its being a compound. About the same time Sir H. Davy commenced his examination of the same body, and from his numerous researches he concluded that it ought to be regarded as an undecomposed body; and on account of its green colour, he gave this gas the name of chlorine. This opinion was at first strongly combated by Dr. Murray and Berzelius, but the latter is now a convert to what has been termed the new theory of chlorine. Chlorine was first obtained by Scheele, by treating the binoxide of manganese with muriatic acid. During the mutual operation of these compound bodies, the oxygen of the binoxide combines with the hydrogen of the acid, and water is formed; the metal of the oxide remains combined with a portion of the chlorine, while the excess which the metal does not unite with is given out in the gaseous state, and possesses the following properties: it is of a greenish colour, and hence the name chlorine, from χλωρός (chlorus), green; it has a very powerful and disagreeable odour, is very suffocating, even when considerably diluted with air, and its taste is astringent. According to Davy, 100 cubic inches weigh between 76 and 77 grains at the average temperature and pressure, and with this determination the experiments of Gay-Lussac and Thénard nearly agree; its specific gravity is consequently about 2·7. Mr. Faraday found that when this gas is subjected to a pressure of about four atmospheres, and kept cool, it is condensed into a yellow limpid fluid, which is extremely volatile, and which, when the pressure is removed, rapidly reassumes the gaseous form; its specific gravity is about 1·33; its refractive power is less than that of water; and it is a non-conductor of electricity.

Chlorine gas is absorbed and dissolved by water, and when this fluid has been recently boiled, it will take up twice its bulk of the gas at common temperatures and pressure: the aqueous solution has the colour, smell and taste of the gas itself. The equivalent of chlorine is 36, and when moist chlorine gas is exposed to a temperature of 32° Fahr., yellow crystals are formed, which are hydrate of chlorine, consisting, according to Mr. Faraday, of very nearly 1 equivalent of chlorine = 36 + 10 equivalents of water = 90. Neither light, heat, nor electricity, produces any change in the properties of chlorine gas, provided it be dry; but if it be moist, then light causes it to decompose the water, the hydrogen of which combines with it to form muriatic acid, while the oxygen is evolved in the gaseous form; and it was this experiment which chiefly induced Berthollet to adopt the opinion of its nature which has already been explained. In the decomposition of the compounds which contain it, it is evolved like oxygen at the positive pole, or anode; except when separated from oxygen, and then it goes to the negative or cathode.

One of the most curious and important properties of chlorine is the power which it possesses of destroying the colour of animal and vegetable matter in general, and hence its extensive application to the purpose of bleaching. [BLEACHING.] When acids alter vegetable colours, they may in many cases be restored by the application of an alkali; but so complete is the destructive power of chlorine, that nothing whatever can reproduce the colour which it has removed. This power appears however to depend upon the intermediate action and decomposition of water, for dry chlorine gas produces no bleaching effect. It follows therefore, that its decolouring power is not direct, but intermediate, dependent upon its decomposing water, and combining with its hydrogen to form muriatic acid, while the nascent oxygen of the water produces the bleaching effect.

Chlorine gas, like oxygen, is a powerful supporter of combustion. If certain metals, and especially antimony, in the state of powder, be thrown into chlorine gas, they burn spontaneously; phosphorus also exhibits similar phenomena.

Chlorine is also a powerful disinfectant; for this purpose it was first employed by Guyton de Morveau, and within a few years compounds of chlorine, or perhaps of chlorous or hypochlorous acid (for the question is undecided), and lime or soda, have been extensively used for this purpose.

Chlorine is in general easily detected by its odour and colour, whether in its gaseous state or in solution in water. It occasions a white precipitate in solution of nitrate of silver, which speedily darkens by exposure to light. This compound is called chloride of silver, and was formerly known by the names of horn silver or muriate of silver. In this case however a portion only of the chlorine is thrown down; part of it uniting with the oxygen of the oxide of silver forms chloric acid, of which we shall presently make mention. It will be observed from the above statement that those compounds which contain chlorine are called chlorides; but this is the case only when such compounds do not possess acid properties.

Chlorine combines with almost every other elementary body, forming compounds of great importance; we shall first state the nature of those to which it gives rise by uniting with oxygen.

Oxygen and chlorine combine in several proportions, but the combination is never immediate; and different views of the number and nature of the compounds are entertained by different chemists. Thus Berzelius mentions one oxide and three acids, viz.,

Protoxide of chlorine	composed of	2	vols.	of chlorine	+ 1	vol.	of oxygen.
Chlorous acid	,,	2	,,	,,	+ 4	,,	,,
Chloric acid	,,	2	,,	,,	+ 5	,,	,,
Oxychloric acid	,,	2	,,	,,	+ 6	,,	,,

Berzelius however admits that there probably exists a peroxide of chlorine composed of equal volumes of chlorine and oxygen, though it has never been obtained. Count Stadion, who discovered oxychloric acid, supposes it contains seven volumes of oxygen instead of six, as above.

Dr. Thomson gives

Protoxide of chlorine	composed of	2	vols.	of chlorine	+ 1	vol.	of oxygen.
Quadroxide of chlorine	,,	2	,,	,,	+ 4	,,	,,
Chloric acid	,,	2	,,	,,	+ 5	,,	,,
Perchloric (oxychloric) acid		2	,,	,,	+ 7	,,	,,

Dr. Turner agrees with the last statements, which indeed differ from those of Berzelius only with respect to oxychloric acid. Dr. Turner however calls the chlorous acid of Berzelius, which is the quadroxide of Dr. Thomson, peroxide of chlorine. According however to Soubeiran, the supposed protoxide of chlorine is a mere mixture of the peroxide and chlorine. The late experiments of Balard seem to prove the existence of what he calls hypochlorous acid, formed of two volumes of chlorine and one volume of oxygen, which is the composition assigned, as just noticed, to the protoxide. Balard remarks, that if both analyses be correct it would be an additional case of isomerism; but he seems rather inclined to adopt the opinion of Soubeiran with respect to the so-called protoxide of chlorine. Leaving however these uncertainties for the present, we shall describe the various compounds above-mentioned. As no doubt exists with respect to its composition, and also for other reasons, we begin with

Chloric Acid.—It has been already mentioned that oxygen and chlorine do not combine by direct action; when however chlorine meets with nascent oxygen they unite. If chlorine gas be passed into water containing oxide of silver diffused through it, a portion of the chlorine combines with the silver and forms a chloride, which is precipitated; and the oxygen expelled from it uniting with another portion of chlorine, constitutes chloric acid, which remains in solution. Any excess of chlorine is to be expelled by heat. Or chloric acid may be made by adding dilute sulphuric acid to chlorate of barytes, in which case sulphate of barytes is precipitated, and chloric acid remains in solution. It is a colourless inodorous acid, which has a sour taste, and reddens vegetable blue colours. The solution may be concentrated by a gentle heat till it acquires an almost oily consistence; it has then a yellowish tint, a peculiar odour, and it sets fire to dry vegetable matters. It combines with bases to form salts termed *chlorates*, which were formerly known by the name of oxygenized muriates, or hyper or oxymuriates. Bodies which have a strong affinity for oxygen decompose chloric acid, by separating that element; thus sulphurous acid is converted into sulphuric acid by decomposing it, and taking its oxygen. Chloric acid is composed of

1 equivalent of chlorine = 36
5 equivalents of oxygen = 40
—
76

The chlorates, except that of potash, are not important salts: this however is used for many purposes; thus when it is heated it evolves very pure oxygen gas, and chloride of potassium remains; the oxygen is yielded both by the acid and the alkali. Chlorate of potash [POTASSIUM] is prepared on the large scale by passing chlorine gas into a solution of the alkali; part of the chlorine takes oxygen from part of the potash and forms with it chloric acid, which unites with the remainder of the potash to form the chlorate, while the remainder of the chlorine unites with the potassium to form chloride; both salts dissolve in water, but the chlorate crystallizes first, and in rhombic plates. This salt detonates when triturated with sulphur; and when struck with phosphorus it explodes and inflames, and in both cases it yields oxygen.

Chlorate of potash is composed of

1 equivalent of chloric acid	=	76
1 equivalent of potash . .	=	48
Equivalent . . .		124

Oxychloric or *Perchloric Acid* is procured by the partial decomposition of the chloric acid just described. It is obtained by mixing sixty grains of chlorate of potash with about four times its weight of sulphuric acid, and heating the mixture below 212° in a glass retort; a gas, which we shall presently describe, is given out, and there remains in the retort a mixture of bisulphate and oxychlorate of potash; by washing with cold water the bisulphate is dissolved, and the oxychlorate remains. When this salt is mixed in a retort with half its weight of sulphuric acid diluted with one third of water, and the mixture is heated to about 280°, the white vapour which arises is oxychloric acid, which condenses in the receiver.

This acid is a limpid colourless liquid, has a sharp taste, and reddens litmus paper, without destroying its colour. When concentrated by evaporation its specific gravity is 1·65, and it then emits vapour when exposed to the air; it boils at 392°, and rapidly absorbs moisture from the atmosphere. When mixed with sulphuric acid and heated, the acid is distilled, and it concretes on cooling into a solid, which crystallizes in prisms. It appears to be the most stable of all the compounds of chlorine and oxygen, not suffering decomposition either by the action of light, sulphurous, or hydrosulphuric acid; it dissolves iron and zinc, with the evolution of hydrogen gas.

The salts formed by this acid into bases are termed oxychlorates or perchlorates: the first is the better name; they are decomposed by heat, yielding much oxygen gas, and are converted into chlorides. The oxychlorates are not an important class of salts.

Peroxide of Chlorine, the chlorous acid of Berzelius, is a gaseous compound evolved during the formation of oxychlorate of potash just described. This gas has a green colour; it has no smell of chlorine, but, on the contrary, an aromatic odour; it is readily dissolved in water, to which it imparts its own colour; the solution does not act upon mercury, nor does it combine with alkalis; it destroys most vegetable blue colours without previously reddening them. When heated to 212° this gas explodes violently, emits a strong light, and the residual gases occupy more space than the compound did which they formed; 40 volumes of the gas becoming 60, of which 40 are oxygen and 20 chlorine.

The changes which occur in thus preparing oxychlorate of potash and peroxide of chlorine are these: the sulphuric acid decomposing a portion of the chlorate of potash evolves chloric acid, which, at the moment of its liberation, is separated into oxygen and peroxide of chlorine; the oxygen combines with the chloric acid of the undecomposed chlorate, and converts it into oxychloric acid, and consequently oxychlorate of potash is formed, while the peroxide of chlorine, as already noticed, is evolved in the gaseous state. It is probable, that when three equivalents of chlorate of potash are acted upon by sulphuric acid, there are produced two equivalents of peroxide of chlorine and one equivalent of oxychloric acid.

Protoxide of Chlorine, the euchlorine of Davy, by whom it was discovered in 1811 This gas is obtained by exposing very cautiously to a moderate heat two parts of chlorate of potash, one of muriatic or hydrochloric acid, and one of water; the products are water, chlorine, and the protoxide of chlorine. The gases should be received over mercury, which absorbs the chlorine and leaves the protoxide.

This gas has a yellowish green colour, more brilliant than that of chlorine; its smell resembles that of burnt sugar; water dissolves eight or ten times its volume of this gas, and becomes nearly of an orange colour. It does not combine with alkalis, but it first reddens vegetable blues, and afterwards destroys them: this gas is very explosive, even the heat of the hand is sufficient to produce this effect. According to Soubeiran, as already noticed, this gas is not a definite compound, but a mixture of peroxide of chlorine and chlorine, and it has been also observed, that Balard's experiments tend to show that the portions of oxygen and chlorine assigned to this compound are such as form hypochlorous acid, which we shall now mention; protoxide of chlorine will therefore be probably removed from the compounds of these elements.

Hypochlorous Acid, to which we have just alluded, is, according to Balard, an acid existing in what is usually called chloride of lime or bleaching powder; and this, as the first-mentioned name indicates, was first supposed by Berzelius to be a chloride of lime, and afterwards a chlorite; but the more recent and minute researches of Balard seem to prove that it is a hypochlorite. This acid is thus obtained: add finely-powdered peroxide of mercury, mixed with twelve times its weight of distilled water, to chlorine gas in a bottle, and shake it well; the oxide of mercury should be slightly in excess, so as that when the absorption of the chlorine, which goes on rapidly, is over, the residue should have a reddish rather than a white colour. The whole contents of the bottle are to be put in a filter, upon which there remains oxychloride of mercury, while the filtered liquor, when distilled in vacuo, yields weak hypochlorous acid, which may be concentrated by redistillation.

Hypochlorous acid thus procured is a transparent slightly yellow-coloured fluid; its smell is penetrating and very distinct from that of chlorine or the peroxide; its taste is extremely strong but not acid. It attacks the epidermis with great activity, even more so than strong nitric acid, and imparts a brown stain to the skin. It is a very unstable compound, decomposing probably even at common temperatures. In hot weather it can be preserved for a few days only, without immersion in ice; when weaker and kept from the light, it may be preserved for a longer time. During decomposition it gives out small bubbles of chlorine gas, and some chloric acid is formed, and this decomposition is accelerated by agitation with angular bodies: it is decomposed by the action of light as well as by that of heat.

When to a concentrated solution of hypochlorous acid an equal bulk of solid dry nitrate of lime is added, a brisk effervescence is produced, which is owing to the separation of pure hypochlorous acid gas, which has the following properties: its colour is very little deeper than that of chlorine; its smell is penetrating like that of the solution; it is completely absorbed by mercury, which is transformed into a red oxychloride. It is best prepared by passing up a little of the gas at a time into a jar filled with and inverted in mercury; the nitrate of lime which is dissolved prevents the action of the liberated gas upon the metal; water dissolves nearly 100 times its volume of this gas; it is decomposed by heat with explosion. The fixed alkalis and the alkaline earths combine with hypochlorous acid.

The hypochlorite of lime, usually called chloride of lime, or bleaching powder, is a compound of great importance, both in the arts [BLEACHING] and as a disinfectant. It is prepared by exposing hydrate of lime to the action of chlorine gas, when a large quantity of it is absorbed, and the result seems to be the formation of chloride of calcium and hypochlorite of lime; the exact composition of bleaching powder is however a subject still under discussion. Another compound, the nature of which is still more problematical, is that formed by passing chlorine gas into a solution of carbonate of soda; the gas is plentifully absorbed without evolving any carbonic acid. This compound, like the hypochlorite of lime, is used as a disinfectant, under the name of Labarraque's soda liquor.

Azote and chlorine combine to form the

Chloride of azote, or more correctly the quadrichloride of azote. This compound was discovered by Dulong in 1811. These gases do not combine by direct action, but when chlorine gas meets azotic gas in the nascent state they unite. It may be prepared by dissolving an ounce of muriate of ammonia in twelve to sixteen times its weight of water, and then inverting a bottle of chlorine gas in the solution. The chlorine is gradually absorbed, and there are gradually formed small drops of an oil-like fluid which sink in the solution: these are the chloride of azote, derived from the combination of the chlorine with the azote of the ammonia.

The properties of this substance are that it is extremely explosive, sometimes detonating spontaneously, but always on the contact of fatty matter, phosphorus, and various other bodies. Its specific gravity is 1·653. It is not solidified by the most intense artificial cold. At 160° it may be distilled, but at 200° to 212° it explodes. The products of the explosion are four volumes of chlorine and one volume of azote, and as these represent equivalents, it is a quadrichloride of azote composed of

Chlorine and hydrogen combine to form the

Hydrochloric Acid, commonly called the muriatic acid: when equal volumes of these gases are mixed and kept in the dark, they do not unite, but if exposed to daylight they combine slowly, and by the direct rays of the sun, the electric spark, or a taper, they unite with explosion, and there is formed a quantity of muriatic acid equal in volume to that of the two gases employed. As 50 cubic inches of hydrogen weigh 1·075 grain, and 50 of chlorine 38 07 grains, their combined weight gives that of 100 cubic inches of the gas, = 39·145 grains, or its specific gravity is 1·228. This gas is colourless, has a very pungent odour, and an acid and acrid taste. It excites coughing, unless largely diluted with air; extinguishes burning bodies when they are immersed in it; and reddens vegetable blue colours strongly. By heat it is merely expanded, but by electricity it is decomposed. The affinity of this gas for water is so great, that when it escapes into the air, it forms a white vapour by combining with atmospheric moisture; water absorbs 400 times its bulk of this gas, and the result is liquid muriatic acid, usually called muriatic acid.

As this acid is largely employed, it is prepared in a more economical manner than the direct formation of the gas, by decomposing common salt with sulphuric acid. For this purpose, 24 parts of common salt, termed chemically chloride of sodium, are mixed in a retort with 20 parts of sulphuric acid, and 12 of water, and into the receiver an equal quantity of water is put; by distillation to dryness, a colourless acid is obtained, which has a specific gravity of about 1·16.

During the mutual action of the salt, acid, and water, a portion of the water is decomposed, which yields hydrogen to the chlorine, and these form muriatic acid, while its oxygen unites with the sodium, to form soda, which with the sulphuric acid constitutes sulphate of soda, which remains in the retort. This solution of muriatic acid has the smell and acid properties of the gas itself; it emits white fumes, and reddens litmus paper. It dissolves many metals, such as iron, zinc, and tin, and forms with them chlorides, the acid being decomposed and yielding hydrogen gas during their solution. These compounds will be treated of as chlorides, under the respective metals. Muriatic acid is largely employed in the arts connected with, or dependent upon, chemical operations, as in dyeing and calico printing, and in making muriate of ammonia, or sal ammoniac [Ammonia]; it unites also with the vegetable alkalis, as morphia, quina, &c., to form muriates; but with metallic oxides, and with the earths, which indeed are so, strictly speaking, it forms chlorides, and not muriates, on account of the decomposition which it suffers, as just explained. When mixed with the nitric acid also, it is decomposed, and a solution of chlorine is obtained, which is used under the name of *aqua regia*, or nitro-muriatic acid, for dissolving gold and platinum.

Chlorine unites with several of the non-metallic bodies; [Bromine, Iodine, Phosphorus, Selenium, and Sulphur]. Having already given an account of boron and carbon, we shall briefly state the nature of the chlorides of these elementary bodies.

Chlorine and boron form

Chloride or perhaps *terchloride of boron*. It was found by Davy that boron, when recently prepared, burns in chlorine gas; Berzelius remarked that if the boron be previously rendered compact, combustion does not occur until these elements are heated. The resulting compound is a colourless gas, which, when freed from excess of chlorine by means of mercury, has the following properties: it is colourless; its specific gravity is 3·942; it is readily soluble in water, by decomposing a portion of which muriatic and boracic acids are obtained: the same effect is produced, accompanied with a white vapour, when the gas escapes into the atmosphere. It combines with ammonia to form a compound, the nature of which has not been examined. Dr. Thomson calls it borochloric acid. It has been supposed to be a terchloride, but the subject requires further investigation.

Chlorine and carbon form four different chlorides; viz. the dichloride, protochloride, perchloride, and $\frac{5}{4}$ chloride. No combination can be effected between these elements by direct action; carbon, even heated to whiteness in the gas, does not form any compound with it. The discovery of these compounds is due to Mr. Faraday. (*Phil. Trans.* 1821.)

The dichloride of carbon was an accidental product which has been only once obtained, and was formed during the preparation of nitric acid from crude nitre and sulphate of iron. It occurred in small soft colourless fibres; it fused when heated, and at 250° sublimed and condensed unchanged. It is insoluble in water, acid, and alkalis, but may be dissolved in hot oil of turpentine and in alcohol, recrystallizing as the solutions cool; it burns with a red flame, yielding much smoke and muriatic acid vapour. It is composed of

1 equivalent of chlorine . .	36
2 equivalents of carbon .	12
Equivalent . . .	48

The *perchloride of carbon*, which it will be most convenient, although not in strict order, to consider next, is composed of

3 equiv. of chlorine	108,	or 1½ equiv.	54
2 „ carbon	12	„ 1 „	6
Equivalent .	120	Equivalent	60
		As a sesquichloride.	

When olefiant gas, a compound of hydrogen and carbon [Carbon], is mixed with chlorine, they combine to form an oil-like liquid which is composed of chlorine, carbon, and hydrogen; by exposure to the direct rays of the sun, muriatic acid and chloride of carbon are formed during its decomposition.

This chloride is solid; its smell is rather aromatic; it is a non-conductor of electricity; its specific gravity is 2. It melts at 320°, and at a higher temperature may be distilled without suffering any change; water dissolves it but sparingly, and it is also soluble in alcohol, æther and oils.

It burns when strongly heated, but is not acted upon either by acids or alkalis; when passed with hydrogen through a red-hot tube, muriatic acid is formed and carbon deposited.

The protochloride of carbon is obtained by passing the perchloride in vapour through a red-hot porcelain tube; chlorine gas escapes in such proportion as to reduce the perchloride to a protochloride, which is a limpid colourless liquid of specific gravity 1·552: it is not solidified at 0° Fahr. and at about 170° is vaporized. When repeatedly distilled it suffers no change. It is composed of

1 equivalent of chlorine .	36
1 „ carbon .	6
Equivalent . .	42

The last is the $\frac{5}{4}$ chloride; it may be formed by distilling a mixture of 8 parts of chloride of lime, 12 of water, and 1 to 1½ part of alcohol.

The chloride of carbon, which results from the mutual action of these substances, is a colourless limpid fluid; its specific gravity is 1·48, and it boils at 141° Fahr. It does not readily burn, and acids and alkalis, when moderately heated, act but little upon it.

It is insoluble in water, but dissolved by alcohol and ether. It is not decomposed by potassium. Like the other chlorides of carbon it is decomposed by being passed over ignited oxide of copper, and its composition, as well as that of the preceding, was thus ascertained.

The $\frac{5}{4}$ chloride of carbon is composed of

5 equivalents of chlorine	180
4 „ carbon .	24
Equivalent . .	204

Medical Uses.—Chlorine, when pure and concentrated, is very deleterious; it acts as an irritant poison. Its action is most violent and speedy when it is brought into contact with the respiratory organs; it then occasions such violent spasm of the glottis, or opening of the windpipe, that instant death may ensue. To enable chlorine to pass this orifice it must be very largely diluted with atmospheric air, or aqueous vapour. A strong solution of it introduced into the stomach causes irritation, inflammation, and death; and even a stream of the gas, or aqueous vapour of it, directed upon the skin, will cause a pricking or stinging sensation, followed by an eruption of pimples or even vesicles. Notwithstanding its formidable properties, it has been used in several cases with such success that no adequate substitute can be found for it. As a disinfecting agent, or means of decomposing and rendering innoxious putrid miasmata, and other sources of disease, it is unrivalled. For this purpose it may either be directly mingled with the air of the infected place, by preparing it on the spot, or by means of one of Morveau's disinfecting bottles; or it may be gradually liberated from some of its combinations, such as the chloride of soda or lime. This last method is best when human beings remain in the apartment; but the former is preferable, when they have been removed, for purifying the wards of hospitals, cells of gaols, or holds of ships. When not in a very concentrated form, the respiratory organs become habituated to breathing it, and the workmen in manufactories where it is used enjoy a marked immunity from epidemic fevers, and attain a considerable age.

From having been observed to allay chronic cough existing among the workmen of certain manufactories, it has been proposed to be inhaled in a diluted state in several chronic affections of the lungs, such as asthma, chronic bronchitis, and even phthisis pulmonaris, or consumption. In the two former it is of some utility, in the latter it is a mere palliative, but is attended with the advantage of destroying the fœtor of the breath, which is distressing both to the patient and attendants. The chlorine employed in this way must be extremely pure, the preparation frequently renewed, of uniform strength of 1½ volume of chlorine in solution, and carefully preserved from the sun-light, which decomposes it. It may be breathed in a small quantity out of a proper apparatus four or five times a day.

A weak solution of chlorine has been employed, introduced into the stomach, with considerable success in indigestion, with loss of appetite, loaded tongue, and foul taste in the mouth.

Its employment in the form of a bath is not common, but occasionally useful, from its irritant effect on the skin. It is doubtful whether it possesses the specific effect upon the liver which some ascribe to it.

In case of poisoning by the gas, inhaling ammonia or sulphuretted hydrogen in small quantity is useful. Should an overdose of the solution be swallowed, chalk, magnesia, or other alkali, or white of egg in water, or a draught of milk, would be proper as an antidote. On the opposite hand, chlorine is said to be a valuable antidote in case of poisoning by hydrocyanic (prussic) acid, sulphuretted hydrogen, or hydrosulphate of ammonia.

CHLORIODIC ACID. [IODINE.]

CHLO'RION, a genus of Hymenopterous insects, of the section *Fossores*. [SPHEGIDÆ.]

CHLORITE. [TALC.]

CHLOROCARBONIC ACID GAS. This acid, called by Dr. Davy, who discovered it, *phosgene gas* (from φῶς light, and γεννᾶν to produce), was formed by exposing a mixture of equal volumes of dry chlorine and carbonic oxide gases to the solar rays; combination takes place rapidly, but without explosion, and they contract to half their bulk; day-light produces the effect slowly, but in the dark it does not take place at all.

Chlorocarbonic acid gas is colourless; has a strong smell, and reddens litmus paper even when dry; it decomposes water, and there are formed hydrochloric and carbonic acid. Several metals when heated in it decompose it; they are converted into chlorides, and carbonic acid is evolved. The specific gravity of this gas is about 3·44; 100 cubic inches weigh about 107 grains; it consists of one equivalent of chlorine 36 + 1 equivalent of oxide of carbon 14 = 50. When mixed with ammoniacal gas it condenses four times its volume, and forms chlorocarbonate of ammonia, which is a white solid salt; when dissolved in the stronger acids it yields muriatic and carbonic acid, but nitric acid dissolves it without effervescence. It is a disalt composed of

1 equivalent of chlorocarbonic acid	.	50
2 „ ammonia	. . .	34
Equivalent	. . . .	84

No other chlorocarbonates are known.

CHLOROCYANIC ACID. [CYANOGEN.]

CHLOROFORME, a peculiar compound fluid, obtained about the same time by Soubeiran and Liebig. To procure it distil a mixture of alcohol and a solution of chloride of lime; separate the product from the liquid distilled with it, shake it with five or six times its volume of concentrated sulphuric acid; pour it off, mix with a little sulphuric acid, distil, and rectify from a little chloride of calcium.

Chloroforme is a limpid fluid; its specific gravity is 1·480, it boils at about 141° Fahrenheit; does not readily burn, but when a glass rod moistened with it is put into the flame of a spirit lamp, it burns with a yellow sooty flame. It is soluble in alcohol and æther; water precipitates it from them; it dissolves iodine, phosphorus, and sulphur; is not decomposed by potassium; but when this metal is heated in its vapour, combustion and explosion ensue, chloride of potassium is formed, and charcoal is deposited.

It is composed of

Three equivalents of	chlorine	36 × 3 =	108
Two „	carbon	6 × 2 =	12
One „	hydrogen	=	1
		Equivalent	121

CHLO'ROMYS. [AGOUTI.]

CHLORO-NITROUS GAS, a compound of chlorine and nitric oxide gases discovered by Mr. E. Davy; he obtained it by treating chloride of sodium with nitric acid sufficient to moisten it; the results are that the sodium is oxidized and converted into soda by the oxygen of a decomposed portion of the nitric acid, and this combining with the undecomposed portion of nitric acid, they form nitrate of soda, while the chlorine unites with the nitric oxide of the decomposed nitric acid, and they form the gas in question.

Chloro-nitrous gas is of a pale reddish colour; its smell resembles but is rather weaker than that of chlorine; it emits fumes when exposed to the air, is absorbed by water, and possesses bleaching power; it is decomposed by most substances which have an affinity for chlorine, as some of the metals, phosphorus, &c. It consists, according to Mr. Davy, of equal volumes of chlorine and nitric oxide gases, combined without condensation.

CHLOROPAL, a silicate of iron. [IRON.]

CHLOROPHÆITE, a mineral found by Dr. Mac Culloch in the Isle of Rum, &c. It occurs in small masses imbedded in basalt or a black indurated ironstone. Its colour when fresh broken is green, which becomes black by exposure to the air. It is brittle and soft enough to be scratched by a quill. Its specific gravity is 2·02. Some specimens are transparent, others are opaque. The lustre is vitreous; the fracture of the transparent sort is conchoidal, of the opaque, intermediate as to conchoidal and granular. (Phillips's *Mineralogy*.)

CHLOROPHANE. [FLUOR.]

CHLOROPHYLE. The colouring matter of leaves has been thus named by Pelletier and Caventou. It is obtained by bruising, pressing, and then washing them with water, and afterwards treating them with alcohol, which dissolves the green colour and wax; when water is added to this solution, and the alcohol distilled, the green substance, which contains wax, floats on the surface of the water; when this is heated with æther, the wax is dissolved, and chlorophyle remains nearly pure. When exposed to light, or the action of chlorine, it is bleached. Acids produce a similar effect, and by the alkalis it is converted into soap. The red tint which leaves assume in autumn appears to be owing to the formation and action of an acid; the green colour is restored by an alkali.

CHLOROPSIS. [MELLIPHAGIDÆ.]

CHOCOLATE NUT TREE. [CACAO, vol. vi. p. 96.; THEOBROMA.]

CHOCTAWS, one of the aboriginal tribes still inhabiting the southern states of the North American Union: they are now entirely restricted to the state of Mississippi, of which they occupy the middle portion, on both sides of the river Yazoo, a tributary of the Mississippi, and the country about the source of the Pearl River. Formerly they were a powerful tribe, but their number has been reduced by war and by emigration to the countries on the banks of the Arkansas. Still they probably do not fall far short of 10,000 individuals. Like some other of the southern tribes in the United States, they have applied themselves to agriculture, especially to the rearing of cattle and swine. Some missionaries have introduced among them the doctrines of Christianity, and have formed a few schools. Their language resembles that of the Cherokees.

CHOCZIM, or Chotim, a small fortified town, in the Russian government of Bessarabia or Kishenew, on the banks of the river Dniester, about 48° 30′ N. lat., and 26° 30′ E. long. Near it there is a small fortress. Its situation opposite the Polish fortress of Kaminiec rendered it a place of note in the wars between the Poles and Turks, and more recently between the Turks and the Russians. In 1739 it was taken by the Russian general Munnich. Population 4000.

CHŒROPOTAMUS, a fossil genus, instituted by Baron Cuvier on the examination of the jaws, whose general form and dimensions are analogous to those of the hog, and which would seem to belong to an animal nearly approaching the Peccaries, but larger. Teeth, six incisors and two canines in each jaw, and seven molars on each side.

Example. — *Chœropotamus gypsorum.* Found in the Paris gypsum.

CHOIR [Church.]

CHOIR, that part of a cathedral, between the chancel and screen, in which divine service is performed: it is separated from the nave by the screen, over which the organ is, in England and Ireland, commonly placed.

The Choir is also the term by which the lay-vicars, or lay-clerks, and choristers, *i.e.* the singers, of a cathedral, are collectively designated. Their number in each cathedral varies, in most cases in proportion to the degree of integrity possessed by the respective dean and chapter at the Reformation, and subsequently. But, generally, the dignitaries contrived to retain as scanty a portion as possible of the musical members of the church, in order to augment their own emoluments; and with the same view deprived, in several instances, that part of the choir which they suffered to remain of no inconsiderable share of the revenues to which it was legally entitled, as in the case of Bangor, in which the court of chancery interposed, and restored to the organist and choir property to a large amount, whereof they had long been most unjustly dispossessed. With some striking exceptions, the choir service is now performed in by no means a reputable manner, owing partly to the paucity of singers, but chiefly to the lowness of their salaries, which, in a majority of cases, are hardly equal to the wages of the humblest mechanic; consequently, the musical duties of our cathedrals too often are allotted to persons either unqualified, or dissatisfied and negligent.

CHOISEUL, ETIENNE FRANÇOIS, DUC DE, born in 1719, rose to the highest offices in the state under Louis XV., and was in fact the ruling minister during a great part of that reign. He was made minister for foreign affairs in 1758, minister at war in 1761, and some years after he resumed the department of foreign affairs. He held this last office till December, 1770, when, in consequence of his imperious character, which had made him many enemies at court among men of all parties, the most influential of whom were the Maréchal de Richelieu, the Duc d'Aiguillon, and the Ex-Jesuit Abbé de la Ville, he was dismissed from office, and exiled to his estate of Chanteloup, where he wrote his memoirs and a satirical comedy against the royal family, and especially against the Dauphin, afterwards Louis XVI., styled 'Le Royaume d'Arlequinerie,' which he printed himself at Chanteloup, and distributed among his friends. His memoirs were published at Paris in 1790, after his death. The administration of the Duc de Choiseul was singularly unfortunate. In the war against England, which terminated by the peace of Paris in 1763, France lost Canada, and her fleets, as well as those of Spain, were defeated; and in the seven years' war France took the part of Austria against Frederic of Prussia, who triumphed over both. The Duc de Choiseul is also accused of not taking advantage of a party in Poland which, after the death of Augustus III., was disposed to offer the crown to the prince of Conti, and the result was that Catharine of Russia placed the crown of Poland on the head of her favorite Poniatowski. The duke of Choiseul's partiality for Maria Theresa of Austria has been also strongly censured. He concluded the marriage between Marie Antoinette and the Dauphin, afterwards Louis XVI. In 1760 he expelled the Jesuits from France. He is also said to have secretly encouraged the first symptoms of discontent among the English colonies of North America.

The personal character of the duke was generous though haughty; he was disinterested and splendid in his expenditure, by which he ruined his own fortune. He loved the arts and literature, and was a friend of Voltaire and the other literary characters of that age. His enemies exaggerated his faults, and attributed to him crimes of which there is not the least evidence. He died at Paris in May, 1785. (*Examen du Ministère du Duc de Choiseul* in the *Mémoires du Duc d'Aiguillon.*)

CHOKE-DAMP. [Carbonic Acid Gas.]

CHOLÆPUS. Illiger's generic name for the two-toed sloths. [Unau.]

CHOLERA, from χολή and ῥέω, signifying *bile-flux*, a disease which has derived its name from its supposed cause, a preternatural quantity and a morbid quality of the biliary secretion.

The first symptom of this malady commonly consists of griping pains of the bowels; these are soon followed by vomiting and purging: there is always a redundancy and an altered condition of the bile, and, in some cases, after the vomiting and purging have continued for some time, there supervene spasms in different parts of the body, but particularly in the upper and lower extremities, and more especially in the legs. The tongue is usually dry, the thirst urgent, and the urine scanty. The pulse, at first free and frequent, as the disease advances becomes smaller and weaker, and the strength is very rapidly reduced. This form of the disease is commonly termed *bilious cholera.*

The chief exciting causes of this malady appear to be particularly connected with temperature. It rarely if ever attacks in the spring, at least in this country, while it is seldom altogether absent in the latter part of summer, and particularly when summer is passing into autumn. Hence its exciting cause would appear to be not so much a high temperature as an alternation of temperature from heat to cold, such an alternation constantly taking place at this season of the year, and occurring every day, in the great difference that takes place between the temperature of the day and that of the night. Accordingly this disease is observed to be by far the most frequent and the most severe at the seasons when those alternations are the most remarkable; when, for example, cold easterly or northerly winds suddenly set in after hot weather, and, above all, when this cold is combined with a moist atmosphere, as 'during very warm summers and autumns occurring after a very rainy winter and spring, or after a succession of wet seasons, and when the days have been warm, bright, and sunny, and the nights cold with heavy dews.' When such a concurrence of circumstances takes place in a high degree, the disease becomes so prevalent as to be as truly epidemic as any of the forms of fever common to the climate.

It is generally conceived that the use of certain kinds of fruit which abound at this season, as cucumbers and melons, and certain vegetables, as peas and the undressed vegetables used in salads, are powerful concurrent causes. In persons very much predisposed to this malady, such articles of diet may co-operate with the season to produce it; but when the state of the season is such as to render the disease epidemic, it attacks numbers of persons who never use food of this kind. Animal food of a bad quality or too long kept, as animal food of all descriptions is very apt to be at this season of the year, is a much more powerful concurrent cause. So also is excess of food, though of the best quality, and intemperance in the use of malt, vinous, and spirituous liquors, together with whatever causes tend to diminish the vital energies, and so to lessen the power of resistance inherent in the body to the influence of noxious agents.

There is reason to believe that certain poisonous particles of matter, derived from decayed vegetable and animal substances, and diffused in the atmosphere, are among the most powerful exciting causes of cholera, as it is certain that they are of fever. Hence it has been observed that to certain districts in some southerly climates, particularly between the tropics, bilious cholera may be said, from the frequency of its occurrence, to be strictly endemic, although in a less marked degree than certain forms of fever or dysentery. 'According to my own observation,' says Dr. Copland, 'and that of several friends whose range of experience has been great, bilious cholera is very prevalent in situations which are subject to emanations from decayed vegetable matter or putrid matter of any description, particularly from swamps, moist grounds, the banks of rivers, lakes, or canals, &c., and from foul drains or cess-pools, during warm seasons, or wide and rapid changes of temperature; or when the thermometer rises high during the day, and sinks low towards the night and morning.'

The presence of these miasmata as the cause of cholera accounts for the much greater prevalence and severity of this disease, in this country, in antient than in modern times. The account given by Sydenham, who wrote about the middle of the seventeenth century, of the regular annual return of cholera and of its great fatality, may well make us rejoice at the altered condition as to cleanliness of our streets, drains, and houses, and at the different kind and better quality of our food.

'This disease,' says Sydenham, writing of cholera as it appeared in London in the year 1699, 'comes as certainly at the latter end of summer and at the approach of autumn as swallows at the beginning of spring, and as cuckows at the heat of the following season. That disease which is occasioned by a surfeit comes at any time; the symptoms are indeed alike and the cause the same, yet it is of another kind. The cholera is easily known, for there are violent vomitings and an evacuation of ill humours with great difficulty and trouble by stool: there is a violent pain and inflammation of the belly; a heart-burning, thirst, a quick pulse with great anxiety, and often a small and unequal pulse with great nausea and sometimes a colliquative sweat, contractions of the arms and legs, fainting, a coldness of the extreme parts, and such like symptoms, which frighten the bye-standers and kill the patient in twenty-four hours.'

The persons most liable to bilious cholera are either those whose bowels are preternaturally irritable, and who are consequently subject to diarrhœa, or those whose bowels are torpid, and who are consequently subject to habitual constipation. In the latter case it is probable that the biliary secretion is sometimes long retained in the gall-bladder, where it becomes changed in nature, and acquires irritating properties.

Bilious cholera is rarely fatal in this country, excepting at seasons when the concurrence of circumstances is peculiarly favourable to the production of a severe form of the disease, and when at such seasons it attacks persons very much predisposed to it, and whose constitutions have been previously enfeebled by other causes. Its ordinary duration is from twenty-four hours to three or four days, when it often spontaneously disappears; but in general medical aid is indispensable; and when the attack is severe, if such aid be not promptly afforded, the danger of the disease and the difficulty of the cure are very seriously increased.

The milder forms of bilious cholera may pass away without the occurrence of any degree of spasm; but when the attack is severe, spasm is as constantly present as vomiting or purging. And cases now and then occur in which the spasm comes on so early and is so prominent as to give its own name, *spasmodic cholera*, to the disease. Spasmodic, by no means as frequent as bilious cholera, is on the other hand a much more formidable malady. It is indeed the same in nature, and arises from precisely the same causes, but its intensity and danger are widely different. Its attack is often immediately preceded by a sense of chilliness or a distinct rigor; the griping pains are more severe than in bilious cholera; the vomiting and purging are more urgent; the matter rejected consists of a watery or slimy fluid, and very soon there come on painful and violent spasms, which attack the muscles of the abdomen, thighs, legs, thorax, and lastly the arms and hands. These symptoms are attended with a small, quick, and contracted pulse, great thirst, and the immediate rejection of whatever is taken into the stomach. 'As the disease proceeds,' says Dr. Copland, who witnessed its progress in an intertropical climate, and who experienced it in his own person, 'the pulse becomes weaker and smaller; the spasms more general; the purging constant and painful, generally with tenesmus; the vomitings are renewed upon the ingestion of substances into the stomach; and the powers of life rapidly fail. During this time the fluids evacuated from the stomach and bowels present no appearance of bile, although occasionally bile is seen in the evacuations to a small extent. In the course of a few hours the features shrink, the hands and feet become cold and clammy; the exacerbation of the spasms forces out a cold clammy sweat on the face and breast; the pulse is extremely small and weak, or nearly disappears. In a case which came before me in Africa, in 1816, the pulse could scarcely be felt four hours from the attack; and the contents of the stomach are now, in the more dangerous cases, thrown off without any effort of retching. Commonly during all this time the fæcal matters and the biliary secretions are retained, apparently owing to the extension of the spasms from the duodenum to the common biliary duct, and to spastic constrictions of parts of the colon; the epigastrum and hypochondria being sore, tense, and tumid. When the disease is treated with decision, the vomitings cease; free evacuations with a discharge of bile take place, and the patient soon recovers. But if neglected, or improperly managed, the powers of life fail rapidly; the eyes sink, and are surrounded with a livid circle; the countenance assumes a remarkably anxious cast, or is pale, wan, and shrunk; and the spasms extend to the very fingers. The breathing now becomes extremely laborious; the patient is restless, and at last is carried off, sometimes in the space of ten or twelve hours.'

The pathological state constituting the disease seems to consist of irritation of the mucous surface of the digestive tube, commencing in the duodenum and extending in each direction to the stomach, small intestines, and along the common duct to the gall-bladder and liver, with increased action of the muscular coats of these viscera and determination of the circulating fluid to them. This irritation or morbid excitement, owing to the connexion of the organic nerves supplying those parts, is propagated to the spinal nerves, by which the muscles of the abdomen and extremities are affected by painful and violent contractions; and it is chiefly owing to the exhaustion of the vital manifestations of the organic system of nerves, and to the frequent and profuse discharges, that a fatal issue takes place: the circulating organs, which are actuated by this system, being in consequence incapable any longer of performing their functions.

In regard to the treatment, Sydenham recommends in the early part of the attack the promotion of the discharge of the offending matter by means of diluents, such as weak broths and soups; and since his time this practice has been very generally followed. When the discharge has continued some time opium is indispensable, which is best given in the form of pill, in doses of from one to three grains, repeated at short intervals. The muriate of morphia, in doses of from half a grain to two grains, is also an excellent remedy. In some cases the opium should be combined with calomel; and in the intense forms of this disease, common in warm climates, twenty grains of calomel combined with opium, repeated once or twice after an interval of from three to six hours, is found by experience to be the most effectual remedy. Under such circumstances these large and repeated doses of calomel do not salivate, partly because the whole of the calomel is never retained, and partly because the system is not in a condition favourable for the absorption of what does remain in the stomach.

The malady, new to this climate, which has spread to so many different nations of the globe, and which has swept away so many of its inhabitants, commonly known under the name of *pestilential cholera*, is a totally different disease from that here treated of, and is noticed under the article PESTILENCE.

For a more minute account of the symptoms, and for the details of the treatment of bilious and spasmodic cholera, see Sydenham's works; Dr. James Johnson *On Diseases of Intertropical Climates*; Dr. Chisholm *On Diseases of Tropical Climates*; and Dr. Copland's *Dict. of Practical Med.*

CHOLESTRINE, the crystalline matter which constitutes the basis of most of the biliary concretions of man. It is inodorous, insipid, insoluble in water, but soluble in hot alcohol, from which it separates on cooling. When treated with nitric acid it acquires the properties of an acid and is called cholestric acid. [CALCULUS.]

CHO'LIAMBIC, the name of a kind of verse employed by Greek and occasionally by Latin writers (*e. g.* Martial). It consisted of six feet, and was regulated by the same general laws as the iambic verse of tragedy. In two or three points it differed considerably: the fifth foot was properly and generally an iambus, though a few instances are found of a spondee in its place: the sixth foot was always a spondee or trochee. From this circumstance the name Choliambus (χωλίαμβος) is derived, which means lame iambus; the metre limps, as it were, in the sixth foot. Anapæsts appear in the first foot, but in no other. Hipponax was one of the earliest writers in choliambic verse, and has therefore been called the inventor of it. The fragments of his poetry have been collected by Prof. Welcker.

Simonides and Callimachus also wrote in this metre, and a few specimens from the latter poet remain. The age succeeding the death of Alexander contained many choliambic writers, who employed the same antiquated dialect that they found in the compositions of Hipponax and others. The fable-writer Babrius [Babrius], who lived a little before the Augustan age, revived the choliambic poetry, and, influenced probably by preceding poets, who had adopted the same metre, he appears not to have considered himself bound by the custom of his own age in the choice of words. (*Philological Museum*, vol. i., pp. 280-304.)

CHOLLET, or CHOLET, a town in France, in the department of Maine et Loire, and on the little river Moine, which flows into the Sèvre Nantaise, about 190 miles S.W. of Paris in a straight line, or 217 miles by Chartres, Tours, and Saumur, in 47° 3′ N. lat., and 0° 53′ W. long.

The town is situated in a pleasant and fertile country, not far from the left bank of the Loire. Before the revolution it had two religious houses, an antient castle in good preservation, and an hospital: the castle and hospital were destroyed in the Vendean war, and the ci-devant convent of the Cordeliers was in consequence converted into an hospital. The population in 1832 amounted to 4657 for the town, or 7345 for the whole commune. The inhabitants manufacture linen-cloth, calico, and handkerchiefs, which resemble those of India, and carry on a considerable trade in cattle.

CHOLULA, a town in Mexico, in the state of Puebla, lying in 19° 2′ 6″ N. lat., and 98° 15′ W. long. It is situated on the table-land of Anahuac, at an elevation of 6912 feet above the level of the sea, according to Humboldt. Cholula is a considerable place, being inhabited by 16,000 souls, but its manufacturing industry is limited to the fabrication of coarse cotton goods. In the country about it are numerous and extensive plantations of maguay, from which plant the natives extract the beverage called *pulque*. Close to the town stands the largest of the Mexican *teocalli*, or pyramids. It is built like the pyramid at Sakhara, in Egypt, in terraces, of which there are four. Its height is 177 feet, and the length of each side of its base is 1440 feet. Its four sides lie exactly in the direction of the parallel and meridian lines. The platform on its top has an area of somewhat more than 50,000 square feet, and in the midst of it is built a church, dedicated to the Lady de los Remedios, in which mass is read every morning by a priest of the Indian race. The prospect from this platform over the adjacent plain, as far as the great mountain-masses of Popocatepetl and Pico de Orizaba, is very grand and striking. This interesting monument of the antient inhabitants of Mexico consists of alternating strata of bricks and clay cement. At no great distance from it are two other teocalli, but of smaller dimensions.

CHONAD, CHANAD, CSANAD or TSCHANAD, a county in the southern part of Hungary, in the province 'Beyond the Theiss.' It is bounded on the north by the county of Bekes, on the south by the territory of Temeswar, on the east by the counties of Sarand and Arad, and on the west by the county of Tschongrad; it lies between 46° and 47° N. lat. and 20° and 22° E. long. Like the surrounding counties, Chonad is a level plain, broken here and there by inconsiderable eminences. The Maros flows along its southern frontier from Sajten to Klarafalva, and, like the Theiss, forms numerous swamps, which are called *Pannahdt* and *Gentschdt*. It is also watered by the Szaraz, a branch of the Maros. Chonad contains 623 square miles, yet does not include more than 2 market towns, 11 villages, and 30 prædia, or privileged settlements. Its population, in 1787, was 35,868; in 1794, 35,992; and, in 1808, 35,447; but it has advanced rapidly of late years, and may at present be estimated at 47,500. The soil is very favourable to the cultivation of every species of grain, especially wheat, which is excellent and very abundant. The culture of the vine is carried on in several places; the best wine is that made at Mako: the tobacco is also in high estimation; and, on the whole, an increased attention has of late years been paid to horticulture. Chonad contains 40,853 yochs, or 58,361 acres, of meadow and pasture land; 88,666 yochs, or 126,657 acres, of arable land; 13,977 yochs, or 19,967 acres, of vineyards, and 5712 yochs, or 8160 acres, of garden ground. The woods and forests occupy 79,526 yochs, or 113,608 acres. A fine breed of horned cattle is reared in this and the neighbouring counties: that of Mako is famed throughout Hungary. Numerous herds of swine are fattened in the oak and beech forests, and much care is bestowed on the improvement of the flocks. In no other part of Hungary is the breeding of horses carried on with more skill and success than in this county, especially in the celebrated 'Mezohegyes,' an institution founded by Joseph II. in 1785, which stands unrivalled in Hungary, and probably in Europe. These royal mews are handsome and extensive, and always contain 3500 of the finest horses, the rearing and training of which employ 500 men and soldiers. From the proximity of the Maros and Theiss, Chonad is supplied with an abundance of fish; honey also is plentiful. No minerals are found here, and the spring-water is very unwholesome.

The county of Chonad is inhabited by Hungarians, Raitzes, Walachians, Sclavonians, and Jews. The Hungarians occupy six villages; the Walachians four, and the Sclavonians one. Of these 1209 are Roman Catholics, 10,293 Greeks, 4245 members of the Evangelical communion of the seigniory of Bekes (for the most part Sclavonians), 6600 of the Reformed church, and 800 Jews. There are very few mechanics, as nearly the whole population is employed in agriculture. The yearly quota of Chonad for the national war expenses is 17,220 florins, about 1730*l*. The whole county consists of only one circle.

CHONAD, or CSANAD, the capital, on the river Maros, contains 6737 inhabitants, and was formerly a place of some importance. Its castle has long since fallen into decay. It was erected into a bishopric by King Stephen I. in the year 1036, but the bishop does not reside here. It has two churches, and is the residence of a Greek protopape. 46° 10′ N. lat. and 20° 35′ E. long. The town of Mako, on the Maros, situated to the east of Szegedin, contains 15,160 inhabitants, and the general meetings of the states of the county are held here.

CHONAD, a village in the county of Torontal, in Hungary. It lies on the river Maros, and contains 5900 inhabitants, a castle, and one Catholic and one Greek church: it was formerly the seat of the bishop of Chonad, who was subject to the archbishop of Colocza. After the conquest of the fortress of Temeswar, in 1716, it was reunited to the Banat of Temeswar, after having continued for 165 years under Turkish dominion.

CHONDROPTERY'GII, or CARTILAGINEI, one of the two great sections into which the class *Pisces* is divided.

In this section we find species which possess, in most respects, the highest degree of organization, while others possess the lowest observed in the class.

The principal character which distinguishes this section from the fishes with true bone (which usually come first in arrangements) is the cartilaginous substance of which the bones are composed, a circumstance arising from the very small quantity of earthy matter which enters into their composition. This earthy matter, when observed, is found to be disposed in small granules, and not in distinct fibres, as in the first section.

The cranium of these fishes is not divided by true sutures but is formed of a single piece: the maxillary and intermaxillary bones are either wanting or rudimentary, and their functions are performed by bones analogous to the palatines, and sometimes the vomer. Many of the vertebræ are often consolidated. The gelatinous substance, which in most fishes fills the intervals between the vertebræ (these intervertebral masses being connected only by a small cord), in this section frequently forms a thick cord, which varies but slightly in diameter.

In the Myxine (*Gastrobranchus cæcus*), no distinct vertebræ are perceivable, their place being occupied by a soft gelatinous tube. In the extraordinary little fish described by Mr. Yarrell in his 'History of British Fishes,' the lancelet (*Amphioxus lanceolatus*), this part is still more rudimentary, consisting only of a slender transparent column.

The Chondropterygii are divided by Cuvier into two orders—those which have their gills free, as in the generality of fishes; and those in which they are fixed,—that is, the external edge attached to the skin. In the former of these orders, the species have but one external gill-opening, and in the latter they have several—generally five. These orders are divided into families and genera, as follows:—

Order 1. Chondropterygii with free gills.

Family 1. Sturionidæ (or *sturgeons*.)
Genus 1. Accipenser.
—— 2. Spatularia.

Family 2. Chimæridæ[*]
Genus 1. Chimæra.
Order 2. Chondropterygii with fixed gills.
Family 1. Squalidæ (*sharks*, &c.)
(The principal genera are)
Squalus,
Zygæna (*hammer-headed sharks*),
Squatina (*angel-fish*),
Pristes (*saw-fish*),
Family 2. Raiidæ.
(principal genera:)
Torpedo (*electric rays*),
Raia (*skate-fish*),
Trigon (*sting rays*),
Mylobates (*eagle ray*),
Cephaloptera.
Family 3. Pteromyzidæ (lampreys, &c.)
Genus 1. Pteromyzon,
2. Ammocœtes,
3. Gastrobranchus,
4. Amphioxus.

CHONDROSE'PIA, Leukard's name for a genus of cephalopoda. [TEUTHIDÆ.]

CHONDRUS (Zoology), a pulmoniferous mollusk. [PULMOBRANCHIATA.]

CHORA'GUS, the name of a public officer at Athens. Each phyle, or tribe, had a choragus (χοραγὸς), who was obliged to provide a chorus to perform at the representations in the theatre, and at many religious solemnities. The office was probably rotatory, though none but rich persons able to bear the expenditure without inconvenience could be forced to take it. (Fred. Aug. Wolf, *Prolegomena in Demosth. Orat. Leptin.* p. lxxxvii.) The choragus had entire charge of the whole choral apparatus: he paid for the dresses and the crowns, and all other decorations. He also provided and paid a teacher (χοροδιδάσκαλος, chorus-teacher), who instructed and trained the choristers in the arts and graces of their profession. Every expense of whatever kind attendant on the equipment of a chorus, either in the theatre or in any other exhibition, was discharged by the choragus. The tribes vied with one another in the splendour of their exhibitions, and especially in the sumptuousness of the choral ornaments: sometimes the expenses incurred by the state were so heavy, that both the treasury and the resources of individuals were exhausted. (See also *Xen. Hipparch.* i. 26.) In some cases the choragus seems to have led the chorus in person, as well as to have defrayed the expenses; and once a choragus acted as flute-player at Sparta. (Müller's *Dorians*, vol. ii., p. 341.) The term choragus included sometimes the gymnasiarch and the hestiator. (Fred. Aug. Wolf, *in Demosth. Leptin. Orat. Comment.* 16, 24.) The former of these had charge of the athletic exercises of the youth; and the latter was obliged to give a banquet to his tribe on occasion of any great holiday or festival: these offices were similar in kind to that of the choragus, which, probably from being the most expensive and important of the three, stands frequently for the whole. The choragus is not to be confounded with the choropoios (χοροποιὸς), who was general chorus-manager to all the tribes. (Xenoph. *Ages*, ii. 17; Müller's *Dorians*, vol. ii., p. 341, *note*.) Some age appears to have been fixed below which it was not competent to a man to be made choragus: a choragus of boys could not be under forty years of age; the age required in other cases is not known. A resident alien or metic (μέτοικος) could not hold the office. Demosthenes was on one occasion a volunteer choragus, and was grievously insulted during his term of office by Meidias. (Demosth. *against Meidias.*) A tripod was the common prize of the successful choragus, who occasionally erected a small building on which he placed the prize. Such is the choragic monument of Lysicrates at Athens, commonly called the Lantern of Demosthenes. (*Elgin Marbles*, ii. 76, 89, &c.)

CHORD (in mathematics), a straight line drawn from one point to another of a curve. [ARC.] The term chord was also used in trigonometry, with sine, cosine, &c., to denote the chord of a circle, in which case it was also called the chord of the subtending angle. But this term, not being wanted, has not passed into pure algebra with sine, cosine, &c. [CIRCLE], so that when used, it must be considered as retaining its primitive sense, namely, that of a straight line, not an abstract number expressing the ratio of a straight line to the radius. To find the chord of a given angle, multiply the diameter by the sine of half the angle. Thus the angle being $23^\circ\ 20'$, and its half $11^\circ\ 40'$, take the sine of the half, which is ·2022176. If the diameter be 100 feet, then the chord of $23^\circ\ 20'$ is 20·22176, or $20\frac{1}{4}$ feet nearly.

To find the chord of a given arc, find the angle subtending the given arc [ANGLE], and proceed as before. The following Table of Chords, to every degree up to 180°, will frequently be useful in rough calculations. The diameter is throughout 10,000, to avoid decimals.

TABLE OF CHORDS (DIAMETER 10,000.)

Angle	Chord.	Angle.	Chord.	Angle.	Chord.	Angle.	Chord.
1	87	46	3907	91	7133	136	9272
2	175	47	3987	92	7193	137	9304
3	262	48	4067	93	7254	138	9336
4	349	49	4147	94	7314	139	9367
5	436	50	4226	95	7373	140	9397
6	523	51	4305	96	7431	141	9426
7	610	52	4384	97	7490	142	9455
8	698	53	4462	98	7547	143	9483
9	785	54	4540	99	7604	144	9511
10	872	55	4617	100	7660	145	9537
11	958	56	4695	101	7716	146	9563
12	1045	57	4772	102	7771	147	9588
13	1132	58	4848	103	7826	148	9613
14	1219	59	4924	104	7880	149	9636
15	1305	60	5000	105	7934	150	9659
16	1392	61	5075	106	7986	151	9681
17	1478	62	5150	107	8039	152	9703
18	1564	63	5225	108	8090	153	9724
19	1650	64	5299	109	8141	154	9744
20	1736	65	5373	110	8192	155	9763
21	1822	66	5446	111	8241	156	9781
22	1908	67	5519	112	8290	157	9799
23	1994	68	5592	113	8339	158	9816
24	2079	69	5664	114	8387	159	9833
25	2164	70	5736	115	8434	160	9848
26	2250	71	5807	116	8480	161	9863
27	2334	72	5878	117	8526	162	9877
28	2419	73	5948	118	8572	163	9890
29	2504	74	6018	119	8616	164	9903
30	2588	75	6088	120	8660	165	9914
31	2672	76	6157	121	8704	166	9925
32	2756	77	6225	122	8746	167	9936
33	2840	78	6293	123	8788	168	9945
34	2924	79	6361	124	8829	169	9954
35	3007	80	6428	125	8870	170	9962
36	3090	81	6494	126	8910	171	9969
37	3173	82	6561	127	8949	172	9976
38	3256	83	6626	128	8988	173	9981
39	3338	84	6691	129	9026	174	9986
40	3420	85	6756	130	9063	175	9990
41	3502	86	6820	131	9100	176	9994
42	3584	87	6884	132	9135	177	9997
43	3665	88	6947	133	9171	178	9998
44	3746	89	7009	134	9205	179	9999
45	3287	90	7071	135	9239	180	10000

To use this Table, roughly, take out the chord of the nearest degree, multiply by the diameter, and divide by 10,000. Thus for a diameter of 2 feet, and an angle of 10° (supposing decimals are to be avoided), take out 872 opposite to 10°, and multiply by 2, giving 1744, which in inches is 20,928, which divided by 10,000, gives 2 inches, and $\frac{1}{10}$th of an inch, very nearly.

An easy method of verifying the preceding Table (if a doubt arise in any case) is contained in the following relations, which apply according as x is greater or less than 120°.

---

[*] We adopt the names of the families as given by Mr. Yarrell. It is proper here to state that the position of the genus Chimæra is doubtful, possessing, as it does, some of the characters of both orders. As regards the gills, we will quote Dr. Richardson's account:—'The Chimæræ,' says this gentleman, 'though placed by Cuvier at the end of the sturionidæ, seem to belong more properly to his second order of the Chondropterygii, in which the gills are fixed; for though there is only one apparent gill-opening on each side, the gills in reality adhere by a large part of their borders, and there are consequently five holes communicating with the external gill-opening.' Cuvier however was not ignorant of these facts when he placed the genus Chimæra in the first of the two orders.

$$\text{ch. of }(x - 120°) + \text{ch. }(240° - x) = \text{ch. }x.$$
$$\text{ch. of }(120 + x) - \text{ch. }(120° - x) = \text{ch. }x.$$
$$\text{ch. of }(180° + x) = \text{ch. of }(180° - x)$$

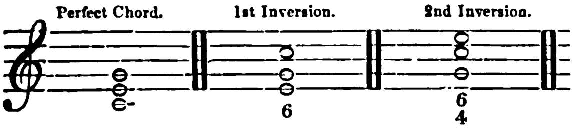
For instance, the chord of 130° is made up of those of 10° and 110°; the chord of 50° is the difference between those of 170° and 70°. These will be true within a unit, if the Table be correct.

CHORD (musical string). [CORD.]

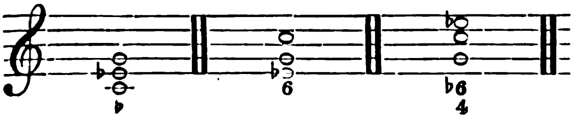
CHORD, in music, is the harmonious combination of three or more musical sounds.

To account for the origin of chords many theories have been proposed, the principal whereof are, that of Rameau,—which D'Alembert endeavoured to elucidate, and Marpurg partly built his system on—and those of Tartini and Kirnberger. These theories, in the main, all arise out of, or finally resolve into, the natural harmonics of a distended string. But it will be proper here to state that Sir John Herschel, in his admirable treatise on Sound, declares 'the insufficiency of any attempt to establish the whole theory of harmony and music on the aliquot subdivision of a musical string.' Nevertheless, the facts that result from the simple division of a stretched string agreeing with the natural harmonic divisions of a sonorous tube—the French horn for instance—and which cannot be disputed, are sufficient to prove that the foundation of what is properly called harmony was not arbitrarily laid. These facts may thus be briefly stated:—the whole string gives, of course, the gravest, or generating, sound; four-fifths of the string give the major 3rd; two-thirds give the perfect 5th; and one-half gives the octave. Thus is produced the perfect or common chord, or triad, which, together with the chord of the seventh, is the source of all other real chords.

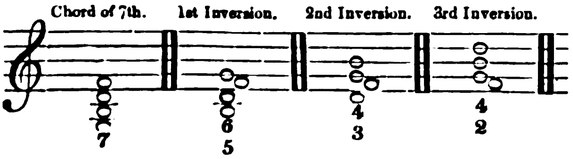
The Perfect Chord consists of any given note, together with a major 3rd and perfect 5th, which sounds may be represented by the letters C, E, G, or by the syllables *do, mi, sol.* It has two inversions, or derivatives: the first is made by taking the E (*mi*) as the base, producing the chord of the *sixth;* the second by taking the G (*sol*) as the base, producing the chord of the *sixth* and *fourth.* Example:—



This chord is denominated the Perfect Minor Chord when its 3rd is flattened; and so altered, its inversions are affected accordingly. Example:—

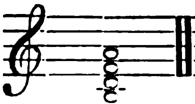


The chord of the seventh—called the dominant seventh—is formed by adding to the perfect chord a minor 7th, and consists of a given note, together with a major 3rd, a perfect 5th and a minor 7th. It may be represented by the letters G, B, D, F, or by the syllables *sol, si, re, fa.* This has three inversions: the first is made by taking the B (*si*) as the base, producing the chord of the *sixth* and *fifth;* the second by taking the D (*re*) as the base, producing the chord of the *fourth* and *third;* the third by taking F (*fa*) as the base, producing the chord of the *fourth* and *second.* Example:—

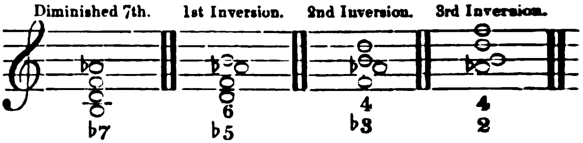


The Perfect Chord and its inversions are called consonant chords: all other chords, and their inversions, are called dissonant chords.

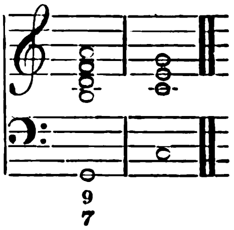
The chord of the Imperfect, or Minor, Seventh, consists of a given note, a minor 3rd, an imperfect 5th, and a 7th. Example:—



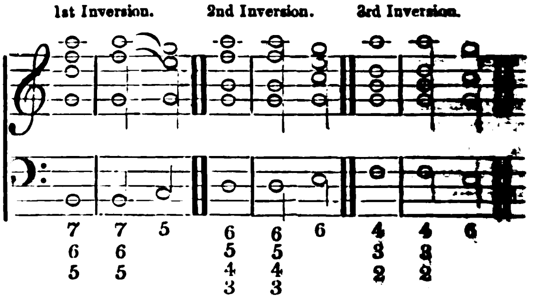
The chord of the Diminished Seventh—sometimes called the Equivocal Chord—consists of a given note, its minor 3rd, imperfect 5th, and diminished 7th. Example:—



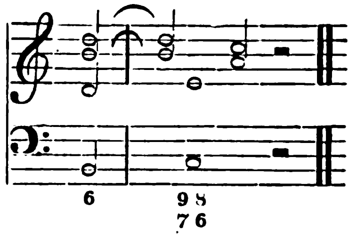
The chord of the Dominant Ninth consists of a given note, its major 3rd, 5th, 7th and 9th. Example:—



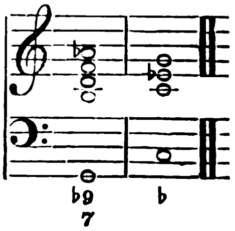
This chord has three inversions, though they are not in very common use. M. Catel gives them in the following manner:—



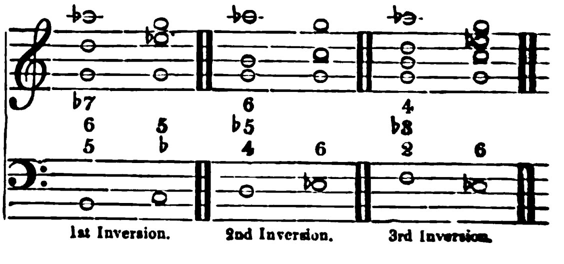
But by far the most elegant form which the chord of the Ninth and Seventh assumes, is as a retardation of the 8th and 6th. Example:—



The Dominant Minor Ninth consists of the same sounds as the Dominant Ninth, but the 9th is flat. Example:—

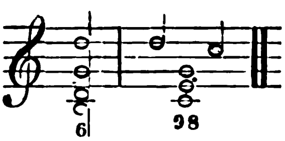


This has three inversions, which also we extract from M. Catel's treatise.

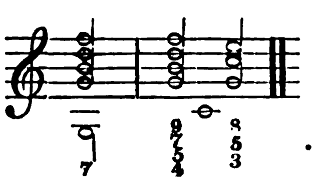


We have seen, that by adding to the perfect chord a 3rd above its 5th, the chord of the Seventh is formed: by the further addition of thirds, theorists form other chords, sometimes called *chords by supposition*. These are, the chord of the Ninth, of the Eleventh, and of the Thirteenth. The last three chords, as well as others presently to be mentioned, are mere chords of retardation: or, in other words, the dissonant notes in them are but appoggiaturas.

The chord of the Ninth consists of a given note, its 3rd, 5th and 9th, the discord retarding the 8th. Example:—

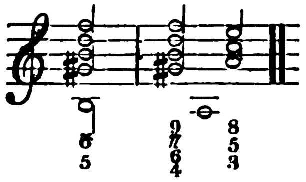


The chord of the Eleventh (more commonly called the chord of the Sharp Seventh), consists of a given note, its 4th (or 11th), 5th, major 7th, and 9th. It is a retardation of the perfect chord, the 9th and 7th retarding the 8th, and the 4th retarding the 3rd, of the perfect chord. Example:—

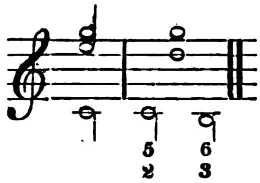


This chord is almost invariably figured by a 7, accompanied by a 5th, 4th and 2nd; but as the discord of the 2nd is always resolved in the base, it cannot, under such name, form a part of the chord of the eleventh.

The chord of the Thirteenth consists of a given note, its 4th, 6th (or 13th), major 7th and 9th. This is a retardation of the perfect minor chord, the 4th and 6th retarding the 3rd and 5th, the 7th and 9th retarding the 8th. Example:—

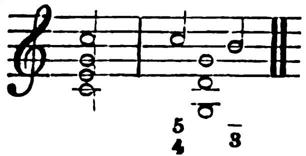


The chord of the Fifth and Second consists of a given note, its 2nd and 5th. Example:—

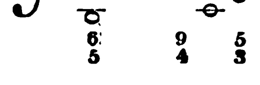


Albrechtsberger considers this chord as one form of the chord of the Eleventh, but the discord being resolved in the base proves it to be a 2nd, not a 9th. It is, in fact, the Sixth retarded by the base.

The chord of the Fifth and Fourth consists of a given note, its 4th and 5th, and retards the perfect chord, the 4th retarding the 3rd. Example:—



The chord of the Ninth and Fourth consists of a given note, its 4th, 5th and 9th. This also retards the perfect chord, the 4th and 9th retarding the 3rd and 8th. Example:—



We will only add that, the nomenclature of chords stands much in need of correction, but, unhappily, it is not the only branch of the theory of music that is confused and perplexing from want of logical accuracy and lucid arrangement.

CHOREA (remotely from the Greek χορεία, and immediately from the Latin *chorea*, a dance with singing—Chorea Sancti Viti—Saint Vitus s Dance), a disease affecting with irregular movements the muscles of voluntary motion, these muscles being no longer under the command of the will, and the power both of walking and of using the arms and hands being impaired. The chief external manifestations of this disease are in the muscles of voluntary motion; but its real seat is in certain internal organs, and more especially in those which belong to the apparatus of digestion. If the history of any case of chorea be carefully examined from the commencement, it will be found that the more manifest disorder has been preceded by deranged appetite, which is sometimes voracious, and at other times altogether lost; by constipated bowels, and by imperfect digestion. There is at the same time a remarkable failure of the general physical strength. The derangement in these organic functions is always accompanied with a greater or less degree of mental disorder. The mind is irritable and fretful, and oftentimes reserved, gloomy, and desirous of solitude. After this state of physical and mental disorder has continued some time, and the languor, lassitude, and general weakness of the system have proportionally increased, there come on irregular and involuntary twitchings of the muscles, particularly the muscles of the face, which at first are thought by the friends of the patient to be merely the effect of imitation. But these convulsive motions progressively increase, until the muscles of the extremities, face, lower jaw, head, and trunk all become agitated with violent and irregular movements. In this case the patient is incapable of walking steadily, his gait is jumping or starting; sometimes he is altogether unable to walk, and seems palsied, while he is equally unable to perform the ordinary motions with the affected arm.

A century and a half ago Sydenham gave the following graphic and correct description of the convulsive motions characteristic of this disease when fully formed. 'First it shows itself by a lameness or rather instability of one of the legs, which the patient drags after him like a fool. Afterwards it appears in the hand of the same side, which he that is affected with the disease can by no means keep in the same posture for one moment; if it be brought to the breast or any other part, it will be distorted to another position or place by a convulsion, let the patient do what he can. If a cup of drink be put into his hand he represents a thousand gestures, like jugglers, before he brings it to his mouth; for whereas he cannot carry it to his mouth in a right line, his hand being drawn hither and thither by the convulsion; he turns it often about for some time, till at length, happily reaching his lips, he flings it suddenly into his mouth, and drinks it greedily, as if designing only to make sport.'

As the disease advances the power of distinct articulation is lost: even the deglutition becomes difficult, in some cases, to such a degree that fluids are forcibly thrown up from the pharynx in attempts at swallowing them; the eyes lose their lustre; the complexion becomes pallid and muddy; the expression of the countenance languid and vacant; and in the severest cases the mouth is variously twisted and the saliva drivels from it; the tongue is protruded irregularly and spasmodically; the eyes are distorted and rolled in various directions, and the sight is occasionally defective. The muscles meantime become soft and flaccid; emaciation takes place; the pulse is weak, but not much quickened; the urine is pale and copious, and the bowels are always constipated.

The mind, irritable from the commencement, is now harassed by painful images and incongruous ideas, which every effort is made to conceal, and various desires and emotions are produced, sometimes without apparent cause. This disordered condition of the mind, when the disease is severe and long continued, ultimately terminates in a state of fatuity, of which the pallid, listless, and vacant countenance is the external sign and expression.

This disease is common to both sexes, but it is much more frequent in the female than in the male, in the proportion of about three of the former to one of the latter It seldom attacks before the 8th nor after the 15th or 16th year of age, although no period of life is wholly exempt from it. The different muscles that are affected, and the different degrees in which they are agitated by the irregular motions, give an endless diversity to the external appearance of different cases; for the convulsive motions are sometimes slight, at other times severe, sometimes partial, at other times general; but most commonly they are partial, and sometimes they are strictly confined to one side. The duration of the disease may vary from a few weeks to many months.

Chorea is often associated with other affections more or less closely allied to it in nature, and alternates with them. In the female it is often observed in connexion with chlorosis, with the suppression of the catamenial discharge, and with hysteria, and in the male with rheumatism, paralysis, and dropsy. Occasionally it terminates in epilepsy, paralysis, dropsy, particularly hydrocephalus, and, as has been stated, complete idiotcy. Cases are on record in which it has terminated in violent convulsions, and inflammation of the brain, followed by coma and death

Such being the occasional issue, the disease ought in no case to be neglected or trifled with, especially when, as is invariably the case, the postponement of the proper treatment greatly increases the difficulty of the cure. In general, under proper management, the disease is removed without difficulty, and the return to health is commonly complete, although this is one of the affections which is peculiarly subject to relapse. It is not at all uncommon for the patient, when apparently cured, to be attacked several times in succession either with the same disease or with some one of the affections into which it has been stated to have so great a tendency to lapse. Still however those relapses are curable by persevering in the proper treatment, and it is remarkable that even when paralysis and idiotcy appear to be fully established they yield far more readily to appropriate remedies than when those affections have been induced by a primary affection of the brain.

Chorea arises in widely different states of the system, and is produced by different causes, and therefore in different cases requires a different treatment. But in the great majority of cases it arises from an accumulation of irritating matter in the alimentary canal, which must be removed by a course of purgative medicines. The choice of the purgative and the duration of the course must depend on the state of the system in each particular case; but in general the purgative must be of an active nature, and the course decided and long continued. At the same time the strict regulation of the diet, both as to the quality and the quantity of the food, is indispensable. As this malady almost invariably occurs in an enfeebled state of the constitution, active exercise in fresh and pure air, and whatever medicines of a tonic nature are best suited to the particular circumstances of the individual case, should be combined with the purgative course of treatment.

When this affection is connected, as it occasionally is, with organic disease of the spinal cord or brain, it is of the last importance to the proper treatment of the case that this organic lesion should be discriminated, and that the remedies proper to it should be promptly applied. From what has been stated it will appear that this is one of the diseases which should engage the anxious attention of parents, teachers, and all who have the charge of young persons of either sex. Not only the health or disease of puberty and adolescence, but the health or disease, physical and mental, of mature age, may depend on their prompt attention to, or neglect of, the very first symptoms of this malady.

CHORLEY, a market-town and parish in the hundred and deanery of Leyland, in the county of Lancaster, 208 miles N.W. by N. from London, 22 N.W. from Manchester, 11 miles S.W. from Blackburn, 9 miles S.S.E. from Preston, 11 miles N.N.W. from Bolton, and 8 miles N. from Wigan. It has no dependent township, and is the only market-town in the hundred of Leyland. The parish of Chorley comprizes an area of 2000 statute acres. The town is situated on a hill in the centre of the county, on the great west road from London to the North. Its name is derived from Chor, a stream that rises at Heapey, two miles distant, and after a short course along the edge of the town, joins the Yarrow and empties into the Douglas. A court-leet and baron was held here for the manor until 1827, when it was discontinued. The manor now belongs to the Fazakerleys, after having passed through the hands of the Sherburnes, the Chorleys, and the Norman families of Ferrers and Lacy. Within the present century the population has more than doubled. In 1801 it was 4516; in 1831, 9282. Seventy years ago the whole town consisted of one irregular street with a shop built across it; now the streets are wide and amount to 67, with a market-square, and about 1820 houses. The town is lighted with gas by a company formed in 1819, and is partially supplied with water by another company formed in 1823. The chief articles of manufacture are calicoes, muslins, and ginghams. Eight cotton-mills and printing and bleaching establishments find employment for a considerable part of the population. The Leeds and Liverpool canal, which joins the Lancaster canal at Whittle-le-woods, passes within about a mile E.S.E. of the town, and furnishes the means of conveying the flags, slates, and mill-stones which are got out of the quarries in the neighbourhood. Coal of good quality is abundant, and in 1833 a large bed of iron ore was discovered near Gillibrand Hall. Lead and carbonate of barytes are found in the Anglezark mines, four miles distant. About one-fourth of the land is arable, and the remaining three-fourths pasture and wood. There are four annual fairs, three of which are principally for cattle, and the last for woollen cloth, hardware, and pedlery. The market is held on Tuesday and Saturday. The town-hall, the basement area of which is used as a market-house, is a stone building, built in 1802 at the sole expense of the late John Hollinshead, Esq. Above this are rooms for the transaction of parochial and public business. The local authority is vested in a constable and visiting magistrates, who hold a petit-sessions once in three weeks.

Chorley was a chapelry in the parish of Croston until 1793, when it became one of three independent parishes, into which the former was divided. The living is a rectory in the archdeaconry of Chester. The parish church, dedicated to St. Lawrence, is an antient structure, supposed to be of Norman origin. The tower is a later erection. In this church a court is annually held by the bishop of Chester, at which he presides by proxy, for the swearing-in of churchwardens for all the parishes in the hundred of Leyland, for proving wills, and for taking out letters of administration. In the patronage of the rector of the parish church is St. George's, an elegant modern structure, built by the parliamentary commissioners at the cost of 13,707*l*. 16*s*. 9*d*., and opened for public worship in 1825. Besides the churches there are dissenting chapels for the Unitarians, Independents, Wesleyan Methodists, and Baptists; and at Weldbank, about a mile south of Chorley, is the Catholic chapel. In the various Sunday schools 2135 children receive instruction. The Grammar-school, adjoining to the churchyard, has but a very small endowment, so that the boys educated there are not taught gratuitously. There is a large and handsome school, conducted on Dr. Bell's plan, built and supported by public subscription; there are also infant schools and a Catholic day-school, which afford gratuitous instruction to nearly 1000 children. Six almshouses, having gardens and a donative of 2*l*. per annum attached to each, were built in 1682 for aged women and widows. Other charities, amounting to nearly 30*l*., are annually distributed among the poor. In 1828 a dispensary was established. The surrounding country is very picturesque, particularly towards the vale of the Ribble. On the north-west of the town is Astley Hall, an antient mansion, the seat of Sir H. P. Hoghton, Bart., and a little farther from the town, in the opposite direction, is Duxbury Hall. The townships adjoining Chorley are Heapey, Hoghton, Wheelton, and Witnell, and Whittle-le-Woods. (*Communication from Lancashire;* Robinson's *Description of the Parish of Chorley*, 1835.)

CHORUS, among the Greeks, was a number of persons, male or female, who sang melodies accompanied with dancing. The chorus appears to have been of Doric origin, and the Doric dialect continued to be chiefly used, even in the choral songs of Attic tragedies. (Müller's *Dorians*, vol. ii., p. 381.) Originally the choral performance was a separate exhibition, and was of a religious character: hymns were chanted in honour of Dionysus and other gods. Afterwards an actor was added by Thespis, who first introduced the dialogue; other changes were made by his successors, especially Phrynichus, till a second actor was added by Æschylus, who embodied the chorus in the constitution of the Greek drama, as a part and only a part of the representation. Many explanations of the object of the chorus have been offered by different writers. It would certainly give a very imperfect idea of its office, to say that it was only retained in order to give the other actors breathing-time, and to prevent a break in the performance. The chorus may be regarded rather as the representation of the aggregate body of spectators: the chorus generally gave utterance to those emotions of pleasure or sorrow which the audience might be supposed to feel. They sometimes took upon themselves to give instruction or to administer reproof.

The tragic chorus consisted at first of fifty, afterwards of fifteen persons; the comic chorus consisted of twenty-four. According to Julius Pollux (*Onomast.* iv. 15), the number of the tragic chorus was abridged after the performance of the Eumenides of Æschylus: the alarm caused by fifty of these ladies was too great. The chorus entered into the orchestra, and remained there performing their evolutions, and observing the thymele or altar, which was in the middle of the orchestra, as the centre of their movements. As they sang they moved in a dance, suited to the subject of their song, and modulated by the accompanying music: sometimes the movements of the dance were so appropriate as to convey to the spectators the full meaning of the chorus, independently of the words of the song. The perfection to which the Greeks carried their skill in affecting an audience by the harmonious union of dancing and music forms one of the main differences between the antient and modern theatre. The modern ballet (properly so called) will probably give the best idea of what this combination was: but by the ballet (properly so called), we understand a ballet which is a species of drama, and not what is now ordinarily presented as a ballet. The songs of the chorus consisted of three parts, the strophe (or *turning*), the antistrophe (*opposite turning*), and the epode (*after-song*): during the first they turned from right to left, during the second from left to right, and during the third they stood still in front of the spectators. When they sang, they all sang: when they took part in the dialogue, one only, the coryphæus or leader of the chorus, spoke, from the top of the thymele; and hence in addresses to the chorus there is a constant change of number—*thou* and *ye*. (Schlegel, *Transl. in Theatre of the Greeks*, p. 265.) Frequently they divided into two sets, who, by means of their two leaders, carried on a separate dialogue, which generally revealed their sentiments on the progress of the plot, their fears, anxieties, and hopes. They also chanted hymns of supplication or thanksgiving to the gods.

The choruses at Athens did not perform exclusively in the theatre, but on many occasions when there was no scenic representation at all. At the Panathenæa and the Thargelia, and at the Gymnopædia of Sparta, choruses of men and boys sang. All choruses at Athens were provided, equipped, and instructed, by persons appointed by the several tribes. [Choragus.]

CHORUS, in music, a composition sometimes in two or three, but generally in four parts, sung by many voices, accompanied by the whole band when performed in an orchestra or on the stage, but by the organ alone when sung in a choir. The chorus of the oratorio and opera has full instrumental accompaniments, but that of our cathedral services and anthems is written with only an organ accompaniment.

The term Chorus is also applied in an aggregate sense to the whole body of singers performing the chorus.

A Double Chorus is in eight vocal parts, and sung by two choirs. Many of Handel's choruses in *Israel in Egypt*, in *Solomon*, and in *Deborah*, are of this kind.

CHOSE IN ACTION is a technical term in the law of England which denotes that kind of property of which the owner is not in the actual possession or occupation, though he has a legal right entitling him to obtain the possession by an action or suit. This sort of property is, for this reason, called a thing (*res*), or *chose* in *action*, in contradistinction from property in *possession*. Thus if I contract to buy a quarter of wheat out of a large quantity, and the seller, in breach of his engagement, refuses to deliver it, my interest in the wheat under the contract is a property to which I have an absolute right, but which, as I have not bought any specific parcel of wheat, I can only reduce into possession through the medium of an action. And as long as I have only the right of enforcing the delivery of the wheat, or an equivalent in damages, and not the actual possession, my property in this respect is a chose in action, being, as a property, a thing rather *in potentiâ* than *in esse*. (Blackstone's *Comm.*, vol. ii., p. 397.) In like manner money due upon a bond or a bill of exchange is a chose in action; and also the right to compensation for damage sustained by means of the breach of any kind of contract.

The antient policy of the English law, in discouraging all contracts tending to promote litigation, introduced a rule that property in action merely, and not in possession, could not be assigned or transferred to any third person. This rule has in modern times received considerable modification. In the familiar instance of bills of exchange and promissory notes (which are strictly choses in action), an indorsement not only transfers to the indorsee the absolute right to the sum to be recovered, but also enables him to sue in the common law-courts upon the bill or note in his own name. Courts of equity in other cases protect assignments of choses in action; but in these cases the assignee must sue in the name of the original contractor, whom the law, regarding the assignment, which it does not sanction, as a nullity, treats as the party still entitled, if the assignee proceeds at law. [Assignment.]

CHOSROES. [Khosru.]

CHOTEESGHUR. [Nagpore.]

CHOUA'NS was the name given to the irregular bands of royalists in the west of France, who continued in arms after the organized insurrection of La Vendée had been suppressed by the first Consul Bonaparte in the year 1800. The Chouans were chiefly on the right bank of the Loire, in the provinces of Bretagne, Maine, and Normandy, while the Vendeans, properly so called, were on the left or south bank of that river. The Vendeans were a regular royalist party, possessing a considerable extent of country, having a kind of discipline in their army, and fighting honourably for their cause. The Chouans, who continued in arms after the Vendeans had submitted, were straggling, disorderly bodies of men, marauding over various provinces of France, hunted after by the troops of the government, and having no fixed station. Some of the royalist officers who had served in the civil wars of La Vendée became chiefs of Chouan parties, but the parties themselves were swelled by many disorderly and desperate characters, who continued a struggle which had become hopeless chiefly for the sake of revenge and plunder. Frotté and George Cadoudal became the chief leaders of the Chouans, after the Vendean chiefs d'Autichamp, Bernier, Bourmont, Chatillon, Suzannet, &c., had made their submission to the first consul. Frotté was taken and shot. Cadoudal withdrew to England, then returned to France, and continued a desultory kind of warfare, mixed up with conspiracies against the first consul, for effecting one of which he went secretly to Paris, and remained several months in that city unknown to the police. He was at last arrested, after killing several of the police, tried, and executed in June, 1804. [Bonaparte.] The Chouans scattered over France had been in great measure put down, and a vast number of them executed previous to Cadoudal's death; still we read of Chouan parties occasionally as late as 1806, under the empire, when one of them arrested the bishop of Vannes in the department of Morbihan and exacted a considerable sum for his ransom. They had then degenerated into mere robbers. In general the name of Chouans was used in an unfavourable sense, while that of Vendeans was respected even by their enemies.

CHOUGH. [Corvidæ.]

CHOUMLA. [Shumla.]

CHRISM, sometimes written **CRISOME**, in its strict interpretation means 'unction,' from the Greek χρίσμα (chrisma), ointment; but is more generally received as the name for oil consecrated by the bishop and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction: and is, or used to be, prepared on Holy Thursday with much ceremony. Ducange (*Glossar. ad Script. Med. et Infimæ Latinitatis*, edit. Francof. ad Mœn., 1681, tom. i., col. 973) says there are two kinds of chrism, the one prepared of oil and balsam, used in baptism, confirmation, and ordination, the other of oil alone, consecrated by the bishop, antiently used for the catechumens, and still used in extreme unction. (See also Durand's *Rationale Divinorum Officiorum*, lib. vi., cap. 74, 84.) The word crisome is also found applied to the cloth which was laid over a child's face when baptised, to prevent the unguent from running off. (See the *Liturgy* compiled in the 2nd year of Edward VI.) Children likewise who die in the first month are called Chrisomes in our Bills of Mortality, probably from the circumstance of the linen-cloth having been so recently laid upon them.

CHRIST, JESUS, was born at Bethlehem, a city of Judæa, in the days of King Herod. The first chapter of St. Matthew contains the genealogy of Jesus deduced from Abraham through David to his reputed father Joseph: the third chapter of St. Luke contains his pedigree from Joseph to Adam. From Joseph to David, the two genealogies are entirely different; but this discrepancy is satisfactorily explained by the commentators. The birth of Jesus was miraculous; 'when his mother Mary (according to the words of St. Matthew) was espoused to Joseph, before they came together, she was found with child of the Holy Ghost.' Joseph, who intended to put her away privately, being warned in a dream by the Angel of the Lord, that what was 'conceived in her was of the Holy Ghost, took unto him his wife and knew her not till she had brought forth her first-born son: and he called his name Jesus.' (Matth. i.) Herod was much troubled at the miraculous circumstances which attended the birth of Christ, and at the coincidence of the place of his birth with the prophecies. In order therefore that the infant might with certainty be destroyed, he gave orders that all the male children in Bethlehem and the neighbourhood under two years of age should be put to death; but Jesus was saved by his parents, who were warned by an angel in a dream to take the child into Egypt. This part of the sacred history is recorded by St. Matthew only. According to St. Luke, when the days of the purification of Mary were accomplished, his parents took him from Bethlehem to Jerusalem to present him in the Temple, after which they returned to their own city Nazareth in Galilee. At twelve years of age Christ disputed with the Jewish doctors in the Temple at Jerusalem, whom he astonished by his answers and his understanding. Towards his parents his conduct was an example of filial obedience. He was not above following the business of his reputed father, which was that of a carpenter; and until about his thirtieth year he fulfilled the common duties of life in an humble and obscure station. His public ministry was preceded by the warnings and admonitions of John the Baptist, the son of a Jewish priest, who called upon the people to repent and believe, for the time was fulfilled, and the kingdom of God was at hand. Christ was baptised by John in the river Jordan, and shortly after commenced his ministry, being about thirty years of age. For about the space of three years he was engaged in the work of promulgating his doctrines, and confirming his divine mission by numerous miracles. In order to diffuse that religion which he came to make known, Christ selected a certain number of persons to be his constant companions, to learn his doctrines, to witness their influence, to testify to the miracles by which their truth was demonstrated, and to be prepared to propagate after his death the truths which he had thus made known. The twelve persons whom he chose are called the Twelve Apostles. They were ignorant persons, who possessed neither wealth, rank, nor education, and yet they were called to root out opinions which were deeply implanted in men's minds, and to overturn systems strengthened by all the influence which antient and venerable authorities exert over the mind. Christ next appointed from among his followers seventy disciples, whom he sent by twos to every place which he himself intended to visit. (Luke x. 1.) This appointment of the seventy disciples is not mentioned by the other evangelists. Many of the Jews being convinced by Christ's preaching, and the miracles which he wrought among them, of his divine mission, the Jewish priesthood were alarmed, and sought some means of accomplishing his death. Being betrayed by Judas, one of the twelve whom he had chosen, Christ was taken before the Jewish court of the Sanhedrim, which had the cognizance of offences against religion, and from thence to the tribunal of Pontius Pilate, the Roman procurator or administrator of the revenues of the province. Before the former he was accused of blasphemy, a charge which was supported by two false witnesses; and before Pilate as a seditious person, and a stirrer up of disaffection, a charge which was also totally without foundation. But the Jews clamoured for his death; and though Pilate saw nothing in the accusations brought against him worthy of capital punishment, he was sentenced to death in compliance with the clamour of the people, and apparently also from fear of some disturbance. In the midst of their scoffing and jeers he was led to the place of execution, and crucified, with circumstances of the greatest cruelty, between two criminals. On the third day Christ rose from the grave, according to his own prediction (Mark x. 34), and during forty days previous to his ascension into heaven he appeared among his disciples, whom he instructed more fully concerning the nature of his mission, which he now left in their hands. Fifty days after his ascension, the disciples, being assembled in Jerusalem at the feast of Pentecost (Acts ii.), were suddenly 'all filled with the Holy Ghost,' and endowed with the gift of speaking all languages. On this occasion three thousand persons were converted and received baptism. Being thus fitted for disseminating in every part of the world the principles of the new religion, the apostles and disciples whom Christ had appointed, scattered themselves throughout various countries, but principally in the east. Matthias had been chosen to supply the place of Judas, the traitor, and an additional disciple, named Saul, afterwards Paul, a person of education, and though a Jew, a Roman citizen of Tarsus, was especially called to co-operate with them.

The history of Christ has been written by four different individuals, whose accounts are received by the Christian world, and some of the arguments for the credibility of their testimony are founded upon the mode in which they accomplished their task. Matthew, who had been a collector of customs, wrote his Gospel in Hebrew for the use of the Jews soon after Christ's death; Mark is believed to have written under the direction of Peter, for the use of the Christians at Rome; Luke, whose Gospel was written for the Heathen converts, was a physician, a companion in the labours of St. Paul, and is supposed to have written his account of Christ while travelling with the apostle; John's Gospel was written after all the preceding, and notices circumstances which the other evangelists had passed over. That part of the New Testament which follows the four Gospels was also written by St. Luke, and gives the Acts of the Apostles, and the history of Christianity, for about thirty years after Christ's death.

The primitive assemblies of the converts to Christianity were called Churches ('Εκκλήσιαι). The converts at Jerusalem formed the earliest Christian society. The church of Antioch, which was founded by Paul and Barnabas, was the second; and its members first received the name of Christians, having previously been called Nazarenes, by way of derision. The first churches or Christian communities were those of Jerusalem, Antioch, Ephesus, Smyrna, Athens, Corinth, Rome, and Alexandria. The churches founded by the apostles were regarded with peculiar veneration in after times. Their authority was appealed to on points of discipline and doctrine, as it was conceived that the letter and spirit of the apostolical regulations had been more rigidly adhered to. The church of Jerusalem may be regarded as the mother of all other churches; but the church at Rome, then the capital of the world, subsequently became, with the churches of Antioch and Alexandria, which were respectively capitals of Roman provinces, by far the most important of all the churches. The four churches of Jerusalem, Antioch, Rome, and Alexandria were formed in the order in which they are mentioned, though some doubt exists as to the title of the church of Rome to priority over that of Alexandria. The church of Rome became the metropolitan of the west, while that of Antioch was regarded as the chief of the eastern churches. As the apostles extended their travels, churches were planted in various parts of Asia. Paul and Barnabas visited the islands of Cyprus and Crete, and various parts of Greece, where they made converts to Christianity. In a second visit to the churches which were formed by Paul, he regulated some of the practices into which the converts had fallen. At Corinth he remained eighteen months, during which period he exerted himself to establish firmly the faith of the Christian believers, which in that church was exposed to peculiar dangers. When unable to visit distant churches, he addressed them in 'Epistles.' Paul next directed his attention to the west of Europe, to nations 'that were yet rude and barbarous.' There is no certain record of this portion of his travels. The writings and labours of St. Paul, who is emphatically called the apostle of the Gentiles, form the most important part of the history of the second period of

Christianity. In less than forty years after the death of Christ the Gospel had been preached in every country of the then civilized world, and in some countries which were in a state of barbarism. In the year 68, that is 37 years after Christ's death, Peter and Paul suffered martyrdom at Rome.

The records as to the other apostles do not afford an adequate idea of the extent of their labours. John was banished to the island of Patmos by Domitian, and there wrote the Revelations. He was subsequently permitted to return to Ephesus, where he wrote his gospel and epistles. He was the last survivor of the apostles, and died a natural death at the close of the first century, about the year 98. The seven churches mentioned by John in the Revelations are Ephesus, Smyrna, Pergamus, Thyatira, Sardis, Philadelphia, and Laodicea.

The Christian religion, as founded by Jesus Christ, and as accepted by all Christians, whatever differences there may be in their opinions, rests for its authority upon the proofs of his divine mission. The history of Jesus Christ, as given in the Four Gospels, presents us with a series of miracles wrought by him from the commencement of his ministry to the crowning miracle of all, his resurrection from the dead, and his ascent into heaven. Whether the miracles recorded in the Gospels actually took place, or not, is a matter of historical inquiry which must be determined from the whole evidence, like any other historical fact. If the miracles are admitted actually to have taken place—if the dead, for instance, were actually raised to life, there are very few who will not allow that He who performed these miracles must have had a particular power which other men have not. It has sometimes been said that the miracles, if true, do not prove a divine mission. But if a man proclaim his divine mission, and perform miracles in confirmation of it; if he predict his own death and resurrection, and actually do die and rise from the dead in accordance with his prediction—this will ever seem to the mass of mankind sufficient proof of a divine mission, and indeed it would be difficult to say what other proof can be asked for. The second proof of the divine mission of Christ to which Christians appeal is contained in the types and prophecies of the Old Testament, which, under various figures, and in a great variety of expressions, of different ages, refer to the future coming of the Messiah, and to his kingdom. A comparison of the passages of the prophets with the passages in the history of Christ, and the application of many of these passages of the prophets by the Evangelists, and even by Christ himself on several occasions, are considered by all Christians to be a proof of the divine mission of Christ, and also a collateral evidence for the truth of those Gospels in which the prophecies are thus fulfilled. The predictions of Christ himself as to his own death, the destruction of Jerusalem, and the condition of his followers after his death, are also appealed to as evidence of his divine mission. The predictions of the prophets were accomplished in Jesus, and the prophecies of Jesus were accomplished in the subsequent history of the religion which he founded.

The diffusion of the gospel, after the ascension of Jesus, by means at first apparently so insufficient for the purpose, is also viewed by all believers as a proof that his doctrines were not of man. And further, that the early preachers of Christianity sincerely believed what they taught, is shown by their inflexible zeal in diffusing the Gospel amidst sufferings and persecutions even unto death; and this strong conviction in the minds of those who had the best opportunity of learning the genuine doctrines of Christianity must be taken as confirmatory evidence of their divine origin.

The religion which Christ came to teach has for its great sanction, the resurrection of the dead, and the doctrine of future rewards and punishments. In the Mosaic law there is no declaration of the doctrine of the resurrection, and of course the sanction of rewards and punishments in a future life forms no part of the law. Before the coming of Christ indeed there was a partial belief of a resurrection among some of the Jewish sects (Matth. xxii. 23; Acts xxiv. 15): but the preaching of Jesus proclaimed in the clearest terms a general resurrection, and rewards and punishments in a future life for all. It is this firm belief in a future state, which gave to the primitive Christians their inflexible courage and their readiness to suffer death; and which, as it was one of the main causes of the success which attended the preaching of Christianity in its early history, so is it now the vital spirit of the Christian religion. [CHRISTIANITY.]

CHRIST CHURCH, OXFORD. In 1524, Cardinal Wolsey, with the assent of King Henry VIII., announced to the University of Oxford his design to found a college there, the foundation of which he almost immediately commenced. By two bulls, one dated in 1524, the other in 1525, he obtained from Pope Clement VII. leave to enrich his college by suppressing twenty-two priories and nunneries, the aggregate revenues of which were estimated at nearly 2000*l.* The king's patent, after complimenting the cardinal's administration, enabled him to build his college principally on the site of the Priory of St. Frideswide: and the name, originally intended to be 'The College of Secular Priests,' was now changed to CARDINAL COLLEGE. The secular clergy in it were to be denominated 'The Dean and Canons Secular of the Cardinal of York,' to be incorporated into one body. He was also authorized to settle upon it 2000*l.* a year clear revenue. By other patents and grants to the dean and canons, various church-livings were bestowed upon them, and the college was to be dedicated to the praise, glory and honour of the Holy Trinity, the Virgin Mary, St. Frideswide, and all Saints. With respect to its constitution, it appears from Wolsey's statutes, still preserved in the college, that it was to be a perpetual foundation for the study of the sciences, divinity, canon and civil law, the arts, physic, and polite literature, and for the continual performance of divine service. The members were to be a dean and sixty regular canons, with forty canons of a second order. The Society, as Wolsey planned it, was to consist altogether of 160 persons, but no mention was yet made of scholars or students. This constitution continued from 1525 to 1530, when Wolsey was deprived of his power and property, and, for two years after, the foundation appears to have been interrupted, if not dissolved. It was to Wolsey's honour that, when all worldly prospects were closing upon him, he pleaded for nothing so earnestly as that his Majesty would be pleased to suffer his college to go on. What effect this had is unknown, but the urgent entreaties of the members of the society, and of the university at large, were at length successful, while at the same time the king determined to deprive Wolsey of all merit in the establishment, and transfer the whole to himself.

Accordingly, in 1532, the society was refounded by the king, under the title of 'King Henry VIII.'s College in Oxford.' The patent is dated July 8th, and orders that the said college be again founded on the same site, ground, and circuit, dedicated to the Holy Trinity, St. Mary, and St. Frideswide, and endowed with 2000*l.* yearly, for the maintenance of a dean and twelve canons, who should form a chapter, or body corporate. Dr. John Hygden, President of Magdalen College, who had been Wolsey's dean, was again appointed to the office. This second foundation continued until May 20, 1545, when the charter was surrendered by the dean and canons into the hands of the king, who dismissed them with yearly pensions, to continue until they could be otherwise provided for.

The king then changed the college into a cathedral church, translating the episcopal see from Oseney where it had been established in 1542. The name of the college now was 'The Cathedral Church of Christ in Oxford of King Henry VIII.'s Foundation;' and the society was declared to consist of a bishop with his archdeacon, (removed from the church of Lincoln,) and a dean and eight canons. All the estates were assigned to the dean and canons, on condition of their maintaining three public professors, of Divinity, Hebrew, and Greek, one hundred students in theology, arts, or philosophy, eight chaplains, and a numerous choir. No change afterwards took place in the number or constitution of the society, except the addition of one studentship. In Queen Elizabeth's reign, the family of Venables of Cheshire giving an estate to this college, it was agreed, upon a composition, that the nomination of a student should be in the heirs of that family, which was confirmed by Act of Parliament in 1601, 43 Eliz. Queen Elizabeth also ordered, in 1561, that there should be an annual election from Westminster School. The other vacancies are filled up by the dean and chapter. By the last letters-patent which were granted from King Henry VIII., the college was to be governed by statutes subsequently to be provided, but none were ever given.

The college is governed by the acts of the dean and chapter, revokable at their pleasure. There is no visitor but the king, or persons commissioned by him.

The benefactions to this college enumerated by the writers on Oxford are few, and consist chiefly of the profits arising from tenements, or sums of money, bequeathed as exhibitions, or for the better maintenance of poor students. Among them the names of Dr. Chaloner, canon of Windsor; Joan Bostock, of New Windsor; Thomas Whyte, citizen of London; William Wickham; William Thurston, Esq., of London; Dr. Richard Gardiner; Dr. Busby, Master of Westminster School; Lady Holford; and Bishop Fell, deserve especial enumeration. It may be observed that the ample endowment of the last foundation, the increasing prosperity of the society, and the rank and opulence of its members, rendered such helps less necessary in this College than in any other of the same university.

The buildings of this extensive and noble establishment have undergone as many revolutions as its foundation. Had Wolsey lived to complete his plan, it would probably have exceeded that of any college in Europe. The priory of St. Frideswide formed its principal site, the church of which serves both for the cathedral and the college chapel, and is at least of Norman, if not in some parts, of earlier date. This church is in the shape of a cross, with a spiral steeple in the centre 144 feet high. The length from east to west is 154 feet. The cross aisle from north to south 102 feet. The height of the roof in the western part 41½; in the choir 37½; and the breadth of the nave and side aisles 54 feet. It has a cloister, and the chapter-house, built about the thirteenth century, is one of the finest specimens of the early style of pointed architecture in England. The first part of the college finished by Wolsey was the kitchen, the fabric of which still retains its antient shape. The workmen next made room for the hall, by levelling a part of the old city wall which ran from Merton and Corpus College gardens behind St. Frideswide's church. They pulled down likewise the parish church of St. Michael at Southgate, standing where the Hebrew professor's lodgings are now built. In the four years which elapsed between laying the first stone and his disgrace, Wolsey had the satisfaction of seeing the kitchen, hall, the whole of the south side, with the greater part of the west side of the large quadrangle, finished according to his design; and to hear the praises which were lavished from all quarters, both at home and abroad, upon his love of literature, his taste, and his munificence. The hall is 115 feet by 40, and 50 in height. The great quadrangle, nearly a square, 264 feet by 261. The north side was intended to be occupied by a large and handsome church, but scarcely had this portion been commenced and the foundations laid, when the fall of its patron put a stop to the work, and this side of the quadrangle remained unfinished for more than a century. Wolsey's quadrangle was surmounted by an open battlement with pinnacles, instead of the present Roman balustrade which was added by Bishop Fell. The north side was finished after the restoration of King Charles II. The western gateway was completed by Sir Christopher Wren in 1682, when the bell was transferred to it commonly called Great Tom, which had formerly been the clock-bell at Oseney. The more modern buildings of this college are Peckwater and Canterbury quadrangles. Peckwater derives its name from an inn or hostel which stood upon the same site, and had been given to St. Frideswide's monastery; it received its present form and elevation in 1705. The library, which forms the south side of Peckwater quadrangle, was commenced in 1716, but was not wholly finished till 1761. The old library stood on the north side of the chaplain's quadrangle, on the other side of the college, which antiently had been a refectory to the convent of St. Frideswide. After the completion of the new library, about 1775, it was converted into rooms. Canterbury quadrangle, adjoining Peckwater, stands on the site of what was formerly Canterbury college or hall. King Henry VIII. transferred this hall with other buildings to the college, subsequent to which it was repaired and fitted up for the reception of students, and remained in that form and condition till 1773, when the old buildings were removed, and the square reconstructed upon a new design, chiefly through the munificence of Dr. Robinson, then Lord Rokeby, archbishop of Armagh, who gave more than 4000*l.* for that purpose. The Doric gateway was erected in 1778, by Mr. J. Wyatt.

Of the eminent persons who have been educated in this college it is impossible to make an enumeration, the magnitude of the establishment, and the high rank in the learned professions to which it has usually led, would extend the full list to a volume. Among the deans who have presided over the college, may be mentioned John Piers and Toby Matthew, afterwards archbishops of York, Corbet bishop of Norwich, Brian Duppa bishop of Winchester, Dean Aldrich, and Atterbury bishop of Rochester. Among the archbishops and bishops who have received their education here, we find the names of Bancroft, Prideaux, Sanderson, Potter, and Tanner; among the statesmen and lawyers, Sir Dudley Carleton, Sir Edward Littleton, Edward Sackville Earl of Dorset, Lord Littleton, William Earl Mansfield, and George Canning; among poets and orators, Sir Philip Sydney, Ben Jonson, Otway, and Villiers Duke of Buckingham. To these may be added Hackluyt, Camden, Gunter and Hooke the mathematicians, Meric Casaubon, Littleton the compiler of the Latin dictionary, William Penn the founder of Pennsylvania, Locke, Lord Bolingbroke and Desaguliers.

The present society of Christ Church, including students, independent members, under-graduates, &c., consisted Dec. 31, 1835, of 920 persons. The present dean is Thomas Gaisford, D.D. (Wood's *Annals of the University*; Chalmers' *History of the Colleges and Halls of Oxford*; Ingram's *Memorials of Oxford*, 4to., 1834; *Oxford Univ. Calendar*, 1834.)

CHRISTCHURCH, a parliamentary borough, market-town, and parish, in the south-west extremity of Hampshire, is pleasantly situated within the angle formed by the confluence of the Avon and the Stour, in the hundred of Christchurch, and division of New Forest West, 20 miles W.S.W. of Southampton, and 93 S.W. from London in a straight line. Its name is derived from its church and antient priory, founded by the West Saxons, in the reign of Edward the Confessor, for a dean and twenty canons. Ranulph Flambard, bishop of Durham, rebuilt the priory in the time of Rufus, and its revenues were greatly augmented by Richard de Redvers, or Rivers, earl of Devon, to whom the manor was given by Henry I. At the dissolution the annual income was 544*l.* 6*s.* (*Speed.*) Fragments of the priory walls are still standing, and of the castle keep, which are more than ten feet in thickness, and in the Norman style. The earliest notice of Christchurch is in the Saxon chronicles, where it is said to have been the military position of Ethelwold during his revolt against Edward. By the Saxons it was called Twyneham-Bourne, and Tweon-ea; and in Domesday Book, where it is mentioned as a burg and royal manor containing thirty messuages, it is called Thuinam. The church is a very fine old structure, in the form of a cross, partly of Norman architecture. From some remains that have been discovered, the town is supposed to have been of Roman origin. In the vicinity appears the site of a camp and entrenchments, with several tumuli and barrows, which have contained human bones. The living is a vicarage, in the diocese of Winchester.

Though the town is a corporation, it is wholly under the jurisdiction of the county magistrates. It sent two members to parliament since the time of Elizabeth: the number was reduced to one by the Reform Act, and the parliamentary borough was enlarged by the Boundary Act. The town is not lighted nor regularly paved, but is amply supplied with water. The salmon fisheries on the coast and river have greatly declined. The population in 1831 of the whole parish was 5344, and of the new parliamentary borough 6077. There is a free grammar-school, a national and Lancasterian school, and several endowed charities. The rivers Stour and Avon, after uniting about a mile and a half below the town, flow into Christchurch Bay, and form a spacious harbour; but from being obstructed by a moving bar of sand, it can be entered only at high water by small vessels drawing five or six feet of water. There is high water twice every tide. Good anchorage in six fathoms water is found in the bay, east of the harbour, two miles from shore. The town has little trade, and does not appear likely to improve in that respect.

CHRIST'S HOSPITAL, London. The hospitals of Christ, Bridewell, and Saint Thomas the Apostle, were founded by the same charter of king Edward the Sixth dated 26th of June, 1553; for the support of which he granted to the mayor and commonalty, and to the citizens of London, numerous possessions within the city of London, and the counties of Middlesex, Essex, Hertford, Buckingham, Cambridge, Kent, Derby, and York. Christ's Hospital was established upon the site of the house of Mendicants or Grey Friars, in Newgate Street, about five years after the king's grant; when about four hundred orphans were admitted, and clothed in russet, which was soon afterwards changed for the dress which they now wear, viz., a blue coat or tunic, reaching to the feet, with yellow stockings, and a round bonnet or cap. The institution has little or no income under the charter. It is apprehended that the estates which were given under it to the city of London were afterwards apportioned to the royal hospitals as the citizens thought fit. All its other estates can be traced to legacies and donations of different periods. At the suggestion of Sir Robert Clayton, then lord mayor, and a considerable benefactor, king Charles II., in 1676, granted a second charter, allowing 1000*l.* a year, for seven years, to establish a mathematical school for forty boys, and an annuity of 370*l.* 10*s.*, payable at the Exchequer, for the especial purpose of educating and placing out yearly ten boys in the sea-service.

The greater part of this hospital was involved in the destructive fire of London in 1666; but by the zeal and liberality of the corporation of London, aided by donations, loans, and the operation of the revenues of the hospital, it soon revived, and was rebuilt under the able direction of Sir Christopher Wren. The buildings, however, having, to a certain extent, fallen into decay, from their antiquity, and the funds of the charity being unequal to their entire restoration upon a plan of suitable uniformity and convenience, it was resolved, at a general court of the governors, on the 28th of January, 1803, to open a subscription for that purpose, when the corporation of London gave 1000*l.*; several of the city companies followed the example, and the donations for this purpose up to 1833, chiefly of individuals, amounted to 38,676*l.* The great work of rebuilding was commenced in 1825: and no expense has been spared in rendering those parts of the hospital which have been completed under the direction of the late Mr. Shaw, at once durable and magnificent.

The governors of the Hospital are the mayor and commonalty of the city of London, represented by the lord mayor, aldermen, and twelve common council-men, who are chosen by the rest of the common council out of their own body, according to an act of parliament obtained in 1782, to settle the disputes between the city of London and the Hospital. Besides the corporation, noblemen and gentlemen of all ranks are governors, who become benefactors to the amount of 400*l.* The number of governors of this kind is not limited. A president is at the head of the charity, who is elected for life, by the body of the governors, and is always an alderman of London. The governors present to the charity in the following manner. The lord mayor presents two, one being extra, as lord mayor; the president, two, and one as alderman; the other twenty-four aldermen present each one annually, provided any children are admitted. If the lord mayor should be president, he has two presentations as lord mayor, and two as president. The treasurer has two presentations, and one in his turn as governor. The ordinary governors fill up the remaining number in rotation, beginning each year when the last presentation ceased.

In 1683 the governors erected a handsome building in the town of Hertford, for both boys and girls at a very early age, where they are nursed and instructed until they are rendered capable of receiving the more advanced education of the foundation in London. The establishment at Hertford, when full, contains 416, of whom about 200 are taught the classics.

The accommodation in the two establishments in London and at Hertford is for 1156, including 80 girls.

In London there are four classical masters, two writing-masters, and two ushers; a mathematical, drawing, and singing master. At Hertford, there are a classical master, writing-master, two ushers, and two mistresses to the girls' school; besides nurses, &c., at each.

The whole gross income of the charity in 1815 was 43,386*l.* The expenses for that year, 40,420*l.* The governors enjoy the patronage of the rectories of Wormshill, in Kent, and Colne Engaine, in Essex; of the vicarages of Clavering cum Langley, Ugley, and the perpetual curacy of Berden, in Essex; of the vicarages of Horley, in Surrey, and Endford, in Wilts; and, alternately with the Haberdashers' Company, of the vicarages of Albrighton, in Salop, and of Bitteswell, Diseworth, and Wigston, in Leicestershire, and the chapelry of Leiston, in Suffolk. (Carlisle's *Descr of the Endowed Grammar Schools of England and Wales*, 8vo., Lond., 1818, vol. ii., pp: 20—37; and the *History of Christ's Hospital*, by the Rev. William Trollope. 4to. Lond., 1834; to which latter work the reader will refer for more minute and copious details.)

CHRIST'S THORN. [PALIURUS.]

CHRISTIANIA, THE PROVINCE OF, occupies the south-eastern portion of Norway, extending from 58° 48′ to 62° 40′ N. lat., and 7° 40′ to 12° 30′ E. long. Its greatest length from south to north is nearly 400 miles, and its average breadth not much short of 100 miles. According to the official statements, its area is 1580 Swedish, or 35,820 English square miles; it is therefore nearly 7000 square miles larger than Scotland. Its population is about 480,000.

The southern part of the province is washed by the Skager Rack, and bounded by a rocky and bold coast, which however only rises to a considerable elevation west of Fredrikvaern, towards the province of Christiansand. It is much indented, and contains several good harbours. The Bay of Christiania, or Christiania Fiord, stretches about 60 miles inland. At its entrance, where the Hval Oërne islands lie, it is about 15 miles wide, but it narrows gradually farther north, and is only eight miles across where it divides into two branches. These branches are from one to three miles wide, and at their respective extremities are situated the towns of Christiania and Drammen. The shores of the bay are formed by rocky but gentle hills, mostly covered with trees.

Along the western and northern side of this province extends the mountain-chain called Norrska Fjellen, or Norway Range, which commonly rises to the line of perpetual snow, and contains some summits far above it, as the Skagstöls Tind, which rises to more than 8500 feet; and the Sneehätten, which attains more than 8300 feet. These are the highest summits in the range, which in width occupies from 70 to 90 miles, this being the average distance between the inhabited places in the contiguous provinces of Christiania and Bergen. By far the greatest part of it is always covered with snow. Two roads traverse this chain. By the southern the town of Christiania is connected with that of Bergen. From Christiania it runs north-west to the northern extremity of the lake of Tyri, and hence along two of the upper branches of the river Drammen. It crosses the highest part of the range south of the Skagstöls Tind, and descends rapidly to the long and narrow Teroen Fiord, from whose shores it runs south-west over a hilly country to Bergen. The northern road leads from Christiania to Trondheim. It runs from Christiania to the southern extremity of the lake of Miösen, then along the beautiful eastern borders of the lake, and afterwards along the Lougen-Elf, nearly to its source, whence it traverses the highest part of the range, east of but near the Sneehättan. It afterwards descends through some valleys to Trondheim. On the uninhabited part of the range are built four small houses for travellers, as a refuge in snow-storms: they are called *field-stuer*, and the most elevated is 4563 feet above the sea.

The western and northern parts of the province are traversed by the numerous offsets of this range. Near the principal chain they are of great height, sometimes rising above the snow-line, as the Halling Skarven, which rises to more than 5400 feet. Farther east they are lower, but even at a distance of 15 or 20 miles from the coast they commonly rise to 1000 or 1500 feet. The valleys between these ranges are narrow, and have only small strips of cultivable land along their rapid rivers; but part of the declivities of the mountains are covered with high trees, and the mountains themselves afford silver, cobalt, and immense quantities of iron. Such is the country north of 61° N. lat., and west of 10° E. long., which contains about three-fourths of the province. The remainder is also very uneven, but the mountains rarely rise above the line of trees, and are clothed with fine forests. Most of them have a gentle ascent, which admits of cultivation; and there are also numerous level tracts between them, though nowhere of great extent, except at the town of Moss, on the eastern shores of the Bay of Christiania. The most fertile districts lie east and north-east from Christiania, along the rivers Glommen, Wormen, and the lake of Miösen, and are known by the names of Hedemarken and Guldbrandtsdalen. They produce rye, barley, and oats, in sufficient quantities to supply them as exports to the other districts of Norway

The eastern districts are drained by the Glommen, the largest river of Norway, which brings down the waters of the great lake of Miösen. Through the middle districts runs the Drammen-elf, whose numerous branches bring down all the waters descending from the Norrska Fjellen, between 60° and 61° N. lat. They unite about 25 miles from the mouth of the river, which falls into the western branch of the Bay of Christiania near Drammen. The southern districts are drained by the Louven-elf, which rises in the high Hardanger Field, runs for some time east, and then continues in a south-eastern direction to its mouth, near Laurvig, where it falls into the Skager Rack after a course of about 140 miles. In the most southern district is the lake Nord Söen, which receives the waters of a considerable mountain-district, forming part of the province of Christiansand. The lake is about 12 miles long, and enclosed with rocks. From its eastern extremity issues a powerful river, the Skeen-elf, or Brevig-elf, which forms some cataracts near the lake, but soon afterwards, at Skeen, becomes navigable for vessels of considerable burden: at its mouth is a bay, called Langesund. At the north-eastern extremity is the lake Fämund, or Fämundsöe (2352 feet above the sea), the largest of the lakes of Norway, about 24 miles long from south and north, and from two to five miles across. From this lake issues the Klar-elf, which enters Sweden, and falls into the lake of Wenern.

All the towns, except Kongsberg, are near the sea. On the east side of the Christiania Fiord is Frederikshall, on an inlet of the sea called Swine Sund, close to the boundary of Sweden, a fortified place with a harbour and 4800 inhabitants. It exports deals and iron, and has a few manufactures on a small scale. Near it, on a rock 400 feet high, is built the fortress of Frederiksteen, where Charles XII. of Sweden was killed in 1718. Frederikstad, at the mouth of the river Glommen, is a fortress, and has a harbour and arsenal. It exports deals: population, 2100. Moss, on the Christiania Fiord, with 2000 inhabitants, is a thriving place, and has twenty saw-mills and an extensive iron-work. In this place the convention was made in 1814, by which Sweden and Norway were united.

On the west of the Christiania Fiord is Drammen, with 7000 inhabitants, at the mouth of the river Drammen; it has a good harbour, and exports timber in logs. In its vicinity is a marble quarry, and higher up the river at Modum a cobalt-mine. Kongsberg, in a narrow wild valley on the Louven-elf, has 3800 inhabitants, and is a mining town; in its vicinity are silver mines, which once gave a considerable produce, but in the beginning of this century very little. Lately however the produce has considerably increased, and in 1828 it yielded more than 2000 marcs. In 1834 a lump of native silver of extraordinary size was found: this town contains a mining-school. Laurwig, at the mouth of the Louven-elf, has considerable mines in its neighbourhood, a good harbour, and 2000 inhabitants. Skeen and Porsgrund, two places on the navigable Skeen-elf, export a considerable number of deals. Near Tonsberg (1600 inhabitants) on the peninsula of Valloe, salt is made.

CHRISTIANIA, the capital of Norway, is in 59° 55′ N. lat. and 10° 50′ E. long., at the northern extremity of the Christiania Fiord, a bay extending about 60 miles inland, into which the river Agger falls close to the town. Except towards the bay, the town is enclosed by high hills and mountains, which on the north are about 5 miles distant, but on the other sides approach much nearer the town. The streets are wide and well paved; the pavement however inclines from each side to the centre of the street, which is thus converted into a common sewer. The houses have rarely more than two stories; but most of them are built of bricks, and a few of stone. It has four suburbs connected to it, which in parts are not paved. Among the public edifices are distinguished the new royal palace, the military academy, and the cathedral. In 1810 it contained hardly more than 10,000 inhabitants, but in 1826 not less than 20,581. This rapid increase is chiefly to be attributed to the circumstance, that Norway, by its union with Sweden, obtained an independent legislative government, which has its seat in this town, and by the erection of a university in 1811. The university was in 1833 attended by about 500 students, and possesses a library of 100,000 volumes, an observatory, a botanic garden, a museum, and other institutions. The sum of 33,000 dollars is annually allowed for its maintenance. Like the universities of Germany, it is rather a school for public officers, than intended to form men of science and learning. The courses last from four to six years, but the student is not bound to reside at the university the whole time. Besides the four faculties, which exist in every German university, Christiania may be considered as a mining academy; and some of the lectures are intended as a preparatory course for young men who are designed to be practical miners. There are besides a military academy, a grammar school, a commercial academy, and school for drawing, and also a society for promoting the prosperity of the country. Manufacturing industry has not made much progress, and the fabrics are woollen cloth, iron utensils, tobacco, &c. The trade in timber is considerable, though less than it was between 1801 and 1805. It exports principally deals and planks, and also a quantity of fire-wood, almost exclusively to England. The quantity of iron which is exported is not great. In one of its suburbs, called Opslo, alum is made to a considerable extent. (Von Buch's *Travels through Norway*; Schubert's *Reise durch Schweden, Norwegen, Lappland, &c.*; *Journal of Education, No. X.*)

CHRISTIAN KNOWLEDGE, SOCIETY FOR THE PROMOTION OF, was formed in the year 1698, and is the oldest society in the kingdom established for the education and religious instruction of the poor. It is an incorporated society, and is supported by the members of the church of England. Owing to the long time that it has been established, some of its early publications are inferior to works of a similar kind which have been more recently issued; and so long as it acted upon the principle of assisting only those schools which made use exclusively of the Society's publications, it tended to perpetuate the use of many books of little value, and kept better ones out of circulation. The establishment of the Bible Society was occasioned by the apathy of this Society relative to an issue of the scriptures in the Welsh language. The Society has latterly been stimulated into a more active course; and a standing sub-committee has been formed, which takes the management of publications relating to 'general literature and education.' The income of the Society is very large: its expenditure for the year ending November, 1834, amounted to 91,522*l.* 1*s.* 11*d.*; and for the same period it circulated 100,913 bibles, 86,061 testaments, and 192,083 prayer-books. The circulation of all its various publications amounted to 2,475,172.

CHRISTIANITY, that system of religion which has for its founder Jesus Christ.

The history of Christianity may be divided into three periods, of which the first embraces the life and ministry of Jesus Christ; the second comprehends the acts of the apostles after the death and resurrection of Christ, and the formation of the Christian church; the third period comprehends the history of the church from the termination of the labours of the apostles to the present day, and is a distinct subject from the history of the first two periods, so far as concerns the essential doctrines of Christianity.

The communities or churches founded by the apostles soon began to differ in various points of doctrine and discipline. From these differences arose a long series of violent disputes and animosities among the various religious parties or communities into which the whole body of Christians was divided. The frame of civil society also, in all the countries into which Christianity was gradually introduced, was necessarily affected by the new religion. Thus the history of the Christian church immediately subsequent to the cessation of the apostles' mission, and indeed we may say during the time of their mission, is inseparable from the history of all the several political societies among which Christianity was established. The history of Christianized Asia, Africa, and Europe, for several centuries, might with more propriety be called the history of the church in this or that country, than any thing else. The word church is here used in that proper and large sense which is pointed out at the end of the article CHURCH.

Viewing, however, the history of the church as a distinct subject, and paying no regard to the events of civil society, except so far as they are immediately and intimately connected with the church (the term here being used in a narrower sense), such a history is generally supposed to possess a sufficient unity of subject, as distinguished from civil history, to form a separate and distinct division of historical inquiry. Accordingly we have numerous histories of the church, whose professed object is to develop the progress of Christian doctrines, of the various opinions on matters of faith and discipline which have divided Christians, and of the various communities or associations into which Christians have been distributed. But these histories, in all ages, being mainly written by the clergy, are often not so much histories of the church as of the clergy; not so much histories of the great body of Christians in this or that country, as of those whose immediate interests were often little identified with the interests of those whom it was their business to instruct. Such a contracted view of the history of Christianity, and of the history of the church in the several countries where Christianity is established, must always appear unsatisfactory to those who, considering the origin of the religion of Jesus Christ, its progress, and its development, as the great subject of the political drama of the civilized world for eighteen centuries, regard the history of *the* church or of *a* church not as in any respect dissociated from civil history, but as a component part of it. Intimately blended with all the relations of life, with all the great events of political society, and now for at least fourteen centuries directing or influencing all the functions of government, and by turns obstructing or retarding the progress of knowledge, according to the various forms in which it has been moulded for political purposes, a history of the church, distinct from the political history of the same nation and the same period, can have little value, except so far as it may be a good history of the clergy. Such a history of the church, however, has been often attempted by men neither deficient in industry nor learning; but the one-sided view which they have taken has never satisfied careful inquirers, and has only had the effect of forming in the minds of those who read much and think little, a certain confused notion of some essential difference between the history of the church and the history of those who, in various ages, have composed that church. On the other hand, writers of what is called history in the usual acceptation of the term, often seem to consider the history of the church as hardly lying within their sphere. It is true that those great events in the history of the church which have changed the face of society are not and cannot be overlooked by such writers; but the influence of the slow and incessant working of the great principle of Christianity, which is intimately blended with all the social systems of all the countries where Christianity is established, and by its all-pervading power penetrates to their remotest and minutest members, and enters into all the recesses of domestic life, is rarely glanced at, and seldom, if ever, duly estimated by writers of history. The history of civilization, which is the history of a continued progress, would appear to every reflecting person inseparable from the history of Christianity, or, in other words, of the church, taking this word in its large and proper sense. The public acts of the clergy as a body receive a place among other public events in our annals and our histories; but as the real history of a people is generally sunk in the history of their rulers, so that of the true church is merged in the history of the clergy.

A history, then, called a history of *the* church, in the sense in which we believe all writers of general church history have understood the term, appears to be a division of history which ought either to be entitled a History of the Clergy and of their Acts and Opinions, or it ought so to be blended with general civil history as to render a separate name unnecessary.

Instead of attempting a history of the church in any sense, which cannot be accomplished in a satisfactory way within the limits of any Cyclopædia, we have treated of the characteristic doctrines and discipline of the various bodies of Christians, whether properly called churches, or improperly so called, under their several heads. (See the Articles CHURCH; CATHOLIC CHURCH, &c.; and ATONEMENT, &c.)

Christianity is at present diffused over a large part of the world; but it can only be said to be established, either by the authority of the state, or by general consent, in the following countries. Christianity is established in all parts of Europe except the Ottoman dominions. In America, it is established in all those countries which are now under the dominion of descendants of Europeans, which are, in fact, the largest and best parts of the continent. In Africa, it exists in Abyssinia in a very corrupt state, and among the Copts of Egypt, who are now very inconsiderable in numbers. In Asia, the Christian religion is established in Armenia, but the number of Armenian Christians must not be estimated by the population of the country, for the merchants of this active and industrious people are found in many parts of Europe and Asia. In Syria, a branch of the Greek church still exists in the mountains of Libanus and the island of Cyprus; another in part of Syria and Diarbekr; and the Nestorians, who also belong to the Greek church, are found in Asiatic Turkey, about Mosul on the Tigris, in Persia, and also in some parts of India under the name of Christians of St. Thomas. In all the foreign dependencies of European powers, and especially those of the British empire, Christianity may be considered as established; though in many cases, as, for instance, in the British possessions in India, the number of Christians is very small, when compared with the natives. But the zealous and persevering labours of European and American missionaries are now diffusing a knowledge of Christianity, and with it, of the useful arts of life, over countries hardly accessible to commercial enterprise; and it may safely be predicted that by their efforts, and the spirit of colonization which distinguishes some of the European nations, Christianity will rapidly spread itself over a much larger part of the habitable globe. The two other religions which occupy so large a portion of the earth's surface, Mohammedanism and Buddhism, are limited as to the sphere within which they can extend their doctrines, and it seems unlikely that they will pass the limits within which they are now confined. But Christianity, being the religion of the most enterprising part of the human race, of those whose life consists in action more than in tranquillity and repose, is in a state of continual progress and diffusion; and it is probably to this difference between the temperament of most of the nations of Europe (a difference in some degree dependent on climate and local circumstances), and those of Asia and Africa, that Christianity still languishes among its comparatively few native professors in Asia and Africa, while the zeal and superior activity of the European race animate the missionaries of the United States and of England to preach the doctrines of Christianity in the very place of its birth, and to rival the old Catholic missionaries in zeal and courage. As the Apostles and the martyrs of the church testified the sincerity of their faith by their willingness to undergo every kind of suffering, and even death; so, in our own days, the apostles of Christianity, penetrating among the most uncivilized and savage tribes of the earth, have exhibited examples of a courage, perseverance, and self-devotion unparalleled in the history of man.

In Africa, Christianity has hitherto made the least progress: and indeed wherever the Mohammedans have settled in that country, it has gradually decayed or disappeared. The Christian churches of the south coasts of the Mediterranean, which were established at an early period in the history of the Church, no longer exist; those of Asia Minor have disappeared, and in Syria and Palestine, the cradle of Christianity, it still maintains a feeble and uncertain existence.

The great Christian churches are—

1. The Greek, or Eastern Church, divided into four principal branches.
2. The Latin, or Western, or Roman Catholic Church, which is single, and undivided.
3. The Protestant Church.

The Protestant cannot be called a Church in the sense in which the Catholic is called a Church, as it is not one undivided community, but consists of numerous independent communities. Still, as distinguished from the Catholic community, the whole body of Protestants is sometimes designated, though improperly, as the Protestant Church.

CHRISTIANSAND, THE PROVINCE OF, comprehends the most southern part of Norway, extending from Cape Lindesnaes (called by our seamen the Naze), or from 58° to a little north of 60° N. lat. It is comprised between the meridians of 5° and 10° E. long. Its length south and north is 140 miles, and its average breadth may be about 100 miles, which gives an area of 14,000 square miles. This computation does not differ much from the official statement, which gives to this province an area of 470 Swedish or 14,100 English square miles, or nearly twice the surface of Wales: its population amounts to 215,000 souls.

Cape Lindesnaes is considered as the southern extremity of the mountain-chain, which traverses Norway from south to north as far as 62° N. lat., and then turns E.N.E. till it joins the Kölen Range at 63° N. lat. This chain is named by modern geographers very properly the Norrska Fjellen, or Norway Range. It begins with Cape Lindesnaes, but does not attain the perpetual snow-line south of 59°; so that those parts of it which are called Heck Field and Bygle do not rise 4000 feet above the sea, which in this parallel is the line of perpetual congelation. But north of 59°, the Iocle Field, Hougle Field, Gute Field, and Hardanger Field, rise somewhat above it. The highest summit of the Hougle Field is 4668 feet. The highest mountain, however, the Gousta-Fell, is not in the principal range, but east of it: the elevation of this mountain is 5535 feet above the sea. From these high mountain-masses, which occupy more than half its surface, the country slopes gradually towards the sea, forming everywhere a rocky, bold, and frequently a high shore, which on the east and south is slightly indented, but on the west forms a bay of considerable extent, the Bukke Fiord. Two of its branches run many miles into the mountains, and terminate at the foot of the high range. The northern and larger is called Närstrand Fiord, and the southern Lyse Fiord. The latter may be considered as separating the mountains from the hilly country which extends southward to Cape Lindesnaes.

The north-eastern part of Christiansand, about the Gousta Fell, is a very high country, called Tellemarken, and inhabited by a poor but hardy and enterprising race of men. The numerous clefts are filled with water, which rushes down in rapids and cataracts with incredible velocity. The waterfall of the Rinkan Foss is 450 feet high. These waters unite in three streams, which fall into the lake of Nord Soën, from which issues a powerful and rapid stream, the Skeen-Elf or Brevig-Elf. The southern districts of the province are mostly wide and fertile valleys, with a warmer climate than could be expected in such a high latitude. Agriculture is duly attended to, and the hills are covered with forests of oak, pine, fir, and birch. These forests are the principal wealth of the country, and supply materials for the building of the numerous boats employed in fishing, and are also an article of export in the shape of planks and deals. The fishery is not important, except that of lobsters, which are perhaps nowhere found in such immense numbers as along the southern coast between Hellesund (east of Christiansand), and Lister Fiord (north-west of Lindesnaes). The principal rivers are the Nid-Elf, which runs about 80 miles, and the Torridals-Elf, whose course is about 100 miles: both are too rapid to be navigated.

Besides the capital, Christiansand, there are the following places: Arendal, north-east of Christiansand, is built on piles, and its streets are formed partly by wooden bridges and partly by canals. Its harbour, which is safe but not large, is formed by the island of Trommoe. Deals and planks are exported, and in its neighbourhood some iron mines are worked. Vessels are also built. The population does not much exceed 2000 souls. Mandal, between Christiansand and Cape Lindesnaes, at the mouth of the Mandals-Elf, has a safe harbour, to which many vessels, when damaged in the dangerous navigation of this sea, resort. It exports salmon, both salt and dried, and has about 3000 inhabitants. Stavanger, on an arm of the Bukke Fiord, called the Tunge Fiord, has a spacious and safe harbour, and its inhabitants, who in 1825 amounted to 3777 souls, are actively employed in fishing and trading. Much earthenware is also made.

CHRISTIANSAND, a town of Norway, situated on the northern coast of the Skagerck, opposite the northern shores of the peninsula of Jutland, in 58° 10′ N. lat., and 8° 20′ E. long. It stands on an extensive bay, where the Torridals-Elf enters the sea: its harbour is safe, and affords a secure shelter for vessels that navigate the Baltic along this rocky coast. The town has long broad streets laid out with the utmost regularity, and covered in the middle with deep sand. The houses, though chiefly of wood, are very neat and pleasant, and separated from one another by gardens. The principal branch of industry is ship-building, this place being situated in the only district of Norway where oak grows, and hence most of the vessels belonging to the merchants of Christiania and Drammen are built here. It exports also logs and deals to England. On this coast lobsters are taken in great numbers, and this fishery extends round Cape Lindesnaes on the western coast of Norway as far as Cape Stadtland. Lobster fishing affords occupation to numbers of people, and the produce of their labour is sent to London. Christiansand is the capital of the province of the same name, and contained, in 1826, 7488 inhabitants.

CHRISTIANSTAD, a town in southern Sweden, in 56° 1′ N. lat., and 14° 5′ E. long. It is the capital of Christianstads Lan, which comprehends the northern and eastern districts of the antient province of Scone or Skåne. The town is built on the river Helge An, which near it enlarges into a small lake, and is fortified. The streets are straight and wide, and the houses mostly built of wood. The harbour of the town is Ahus, a small place about 10 miles from it at the mouth of the river Helge An. The town was founded by Christian IV. of Denmark, towards the middle of the seventeenth century, when a canal was begun, to form a convenient water-communication with the harbour, but as its commerce was, and is still, very limited, this work has gone to decay. Some woollen and linen goods are made here, and good gloves. Population, 2900.

CHRISTIERN II., of Denmark, born in 1481, was the son of King John, and grandson of Christiern I. He ascended the throne on his father's death in 1513. In 1520 he succeeded in having himself elected king of Sweden, which country had been long distracted by civil factions. [MARGARET OF WALDEMAR.] Christiern took an atrocious, but, as he fancied it, an expeditious way of getting rid of all opposition for the future. Having assembled the chief nobles and prelates at Stockholm on the occasion of his coronation, he had them suddenly arrested and publicly executed. He also massacred a number of the citizens of Stockholm. (Puffendorf.) Gustavus Erickson, a descendant of the antient kings, who was a prisoner in Denmark, having contrived to escape, took refuge in the forests of Dalecarlia, where he roused the peasantry, attacked Christiern and his worthy satellite the archbishop of Upsa, defeated them, and drove the Danes from Sweden. [GUSTAVUS VASA.] Soon after Christiern was deposed by his own Danish subjects, who elected Frederick, duke of Holstein, in 1523. Christiern retired to Flanders, whence, after ten years, he set off with some Dutch troops, and made an attempt to recover his Danish dominions. He failed, and being taken prisoner, was put in prison, where he died in Jan., 1559. He has been called the Nero of the North.

CHRISTINA (of Sweden), the daughter of the great Gustavus Adolphus by Maria Eleonora, princess of Brandenburg, was born on the 8th of December, 1626. Her father bestowed great care on her education, and having no son to succeed him was anxious to cultivate in her a strong and masculine disposition. Even when a mere infant he expected that she, as the daughter of a warrior, should hear the roar of artillery without emotion. On his departure for the wars in Germany, Gustavus Adolphus appointed a regency, and, carrying his daughter in his arms, presented her to the assembled states of the kingdom as their future sovereign.

Gustavus fell at Lutzen in November, 1632. Christina, then six years of age, was proclaimed queen by the states, who left her in the hands of regents or guardians,—the five great dignitaries of the crown, who were charged with the administration of affairs and the task of completing the young queen's education. The Chancellor Oxenstiern, an experienced and enlightened statesman, was at the head of these dignitaries, and the other members of the regency were persons of ability and upright intentions. They, however, pursued the plan of education and discipline that had been traced out by the king himself, and to this we must in part, attribute the singular character afterwards displayed by Christina.

From her earliest years she was surrounded by grave masters and scholars, who crowded and oppressed her intellect with Latin, Greek, Hebrew, history, and politics: and for her lighter amusements she was allowed to ride on horseback in masculine attire, to hunt, to shoot, and review troops. The society of her own sex was soon insupportable to her. It is generally stated that she made considerable progress in several antient and modern languages, and in other branches of knowledge, and that at the council table she showed a searching wit and great precocity of reason. But her wit was almost always of that sort which is nearly allied to madness; her knowledge was not digested, and her mind wanted the equilibrium which is given by pure taste and sound judgment. Bayle says she read daily some pages of Tacitus in the original.

In 1644 she took the reins of government into her own hands, and, much favoured by circumstances, acted rather a conspicuous part in the affairs of Europe. She at once finished a war with Denmark, obtaining by treaty the cession of some territory to Sweden; she pressed on the peace with Germany against the advice of Oxenstiern and others;

and finally became a party to the treaty of Westphalia in 1648, by which, in consequence of the victories of her brave troops, she obtained several millions of dollars, three votes in the diet of the Germanic empire, and the cession of Pomerania, Wismar, Bremen, and Verden.

When pressed by the states to marry, she constantly and firmly refused. The assigned motives of her refusal have been preserved in several eccentric speeches which her majesty is said to have delivered without blushing. Among those who aspired to her hand was her own cousin Charles Gustavus, a prince of excellent qualities. In 1649 she was induced by the states to declare him her successor; but she would not allow the prince any share of her sovereign power, of which she was exceedingly jealous. Soon after the naming of her successor was over, she had herself crowned with great pomp, under the title of *King*.

Having now no wars to engage her attention, she gave herself up with all the energy of her character to arts and literature, or rather to a mania of patronizing artists and men of letters. Her court was soon crowded, good being mixed with the bad, the empty pretender with the real man of science, the sage with the buffoon. She attracted to Stockholm, Saumaise (Salmasius), Vossius, Bochart, Huet, Chevreau, Naudé, Meibom, and other foreigners, chiefly Frenchmen. To some of these she gave places and offices; others were mere retainers and hangers-on of the court. Descartes was her guest, but he died there soon after his arrival, his weak constitution, as it is said, being unable to resist the rigour of that northern climate.

Bourdelot, a gossiping intriguing French abbé, who pretended to some knowledge of medicine, and who was retained in quality of her physician, became the great favourite of the queen by flattering her vanity and ridiculing her court of philosophers and men of letters, whose jealousies and jarrings were incessant. This court was expensive and unpopular. Christina spent enormous sums, for so poor a country as Sweden, in the purchase of books, manuscripts, statues, pictures, antiquities, and curiosities. But reverence and affection for her father's memory stifled the murmurs of the Swedes, and when, to the astonishment of every body, she first spoke of abdicating, she was most earnestly entreated to remain on the throne. For some short time after this she showed a renewal of good sense and energy, and a disposition to public business. It was at this interval that Cromwell's ambassador, Whitlock, saw a good deal of her majesty, and that his secretary or follower, Morton, picked up that curious information about her court and herself which was afterwards published in England. (*Journal of an Embassy to Sweden in* 1653, 1654, *from the Commonwealth of England*, by Charles Morton.) Her distate for what she called the splendid slavery of royalty, her desire to indulge in all her caprices in perfect liberty, and (a stronger motive perhaps than any other) her wish of presenting an extraordinary spectacle to the world, soon returning upon her, she formally signified her decided intention of renouncing the crown in May, 1654, and on the 16th of June her abdication took place with great solemnity, she being then only in the 28th year of her age.

Christina reserved to herself the revenues of some districts in Sweden and Germany, the entire independence of her person, and supreme authority, with the right of life and death over all such persons as should enter her service and form her suite. A few days after this public act she set off for Brussels, where she privately abjured the Protestant religion. A little later she publicly embraced Catholicism in the cathedral of Innspruck. People have doubted the sincerity of her conversion, and some of her witty sayings seem to evince no great reverence for the Roman church. From the Tyrol she travelled to Rome, where she made a sort of triumphal entrance, riding on horseback, dressed almost like a man. Here she surrounded herself with poets, painters, musicians, numismatists, and the like. Quarrelling however with some of the college of cardinals, she made a journey into France in 1656. At Paris she of course made a great sensation. Her constant companions were authors and academicians; for the society of her own sex she showed a greater contempt than ever, and the only French woman about whom she seemed to take any interest was Ninon L'Enclos. Her stay in Paris is said to have been shortened by Cardinal Mazarin, who, finding her inclined to engage in some intrigues against his authority, took such measures as rendered that capital an unpleasant residence for her. She, however, returned to France in the following year, and added to her notoriety by committing a murder in the royal palace of Fontainebleau, where apartments were allowed her. Monaldeschi, her master of the horse and chief favourite, who had been entrusted with all her secrets, was suddenly accused by her of a breach of confidence and high treason, and ordered to prepare for death. Lebel, a monk of the order of the Trinity, who was summoned to hear the offender's confession, implored for a pardon, or at least a suspension of so irregular a sentence, but Monaldeschi was forthwith put to death by Sentinelli, another Italian, and the captain of her body guard, in the *gallerie du cerf*, or stag-gallery. The court was offended, but took no public notice of this atrocious act, which Christina justified by stating that by her deed of abdication she had reserved to herself supreme power over her own suite—that she was still a queen wherever she went, and that Monaldeschi was guilty of high treason. Strange to say, she found defenders elsewhere; and among them was Leibnitz, who wrote an elaborate apology, or rather justification of the deed at Fontainebleau. French writers have pretty generally stated that Monaldeschi was only a traitor in love, and that he perished from a fit of jealousy; but there is no proof of any such connexion, which is in opposition to the whole tenor of Christina's life and conduct. The real nature of the offence is a mystery.

Finding herself avoided in France, the queen thought of visiting England, but the Protector Cromwell turned the dark side of his countenance towards her; she therefore did not land in England, but returned to Rome, where she presently involved herself in great pecuniary difficulties, and a quarrel with the pope (Alexander VII.). Upon the death of the king, her cousin, Charles Gustavus, in 1660, she travelled hastily from Rome to Stockholm, where, according to most accounts, she not only showed a regret at having abdicated, but a strong desire to re-ascend the throne. But the minds of the people were entirely alienated, and her change of religion was an insuperable barrier. She returned once more to Rome, which she never again left, except for one or two short intervals, during the remaining twenty-eight years of her life. Through that long period her occupations were various. She took part in several political intrigues; she is even said to have aspired to the elective crown of Poland; she interested herself for the Venetians in Candia, besieged by the Turks; she quarrelled anew with the pope and cardinals, who had liberally supplied her with money; she engaged actively in the Molinist or Quietist controversy; she indulged in the dreams of alchemy and judicial astrology; she violently censured Louis XIV. for his revocation of the Edict of Nantes and *dragonades* against the Protestants of France; she founded an *accademia*, or literary society; she corresponded with many *savans*, and she made a large collection of objects of art and antiquity. The ruling passion, which made her unhappy and ridiculous, was the ambition of influencing great political affairs when all power and influence had departed from her. She died at Rome with great composure on the 19th April, 1689, in the sixty-third year of her age. Though she wrote continually, not much of her writing has been preserved. Her 'Maxims and Sentences,' and 'Reflections on the Life and Actions of Alexander the Great,' were collected and published by Archenholtz, in his memoirs of her life, 4 vols., 4to., 1751. From the somewhat tediously minute work of Archenholtz, who was librarian to the landgrave of Hesse Cassel, and an honest pains-taking man, Lacombe derived the materials for his life of Christina, and D'Alembert his reflections and anecdotes of the same personage. Her 'Secret Letters' and 'Memoirs of her own Life, dedicated to God,' are forgeries. (See Archenholtz, as above; Catteau-Calville's *Histoire de Cristine, Reine de la Suède;* Fortia's *Travels in Sweden; Biographie Universelle;* the works of Bayle—her contemporary and correspondent; Voltaire; and Horace Walpole.)

CHRISTMAS, the festival in memory of Christ's Nativity, the day of which is observed on the 25th of December. St. Chrysostom informs us that in the primitive times Christmas and Epiphany were celebrated at one and the same feast (*Homil. in Diem Nativ. D. N. J. Christi*, Opera edit. Montfaucon, tom. iii. fol. Par. 1718, p. 354), probably from the belief that the rising of the star in the east and the birth of Christ were simultaneous. The separation took place at the Council of Nice, A.D. 325. The Armenians however continued to make but one feast of the two, as late as the thirteenth century.

The learned have long been divided upon the precise day of the Nativity. Some have fixed it at the Passover; others, among whom was archbishop Usher, at the feast of Tabernacles; and it has been observed, that if the shepherds were watching their flocks when it occurred in the field by night, it could hardly have happened in the depth of winter. Be this as it may, the 25th of December has been the day most generally fixed upon from the earliest ages of the church. Sir Isaac Newton, in his 'Commentary on the Prophecies of Daniel,' (Pt. i. c. ii. p. 144,) has a chapter 'Of the Times of the Birth and Passion of our Saviour,' in which he accounts for the choice of the 25th of December, the winter solstice, by showing that not only the feast of the Nativity, but most others, were originally fixed at cardinal points of the year; and that the first Christian calendars having been so arranged by mathematicians at pleasure, without any ground in tradition, the Christians afterwards took up with what they found in the calendars. So long as a fixed time of commemoration was solemnly appointed, they were content. The reader who would know more on this subject, may consult Baronii 'Apparatus ad Annales Ecclesiasticos,' fol. Lucæ, 1740, p. 475, et seq.; and a curious tract entitled, 'The Feast of Feasts; or, the Celebration of the Sacred Nativity of our blessed Lord and Saviour Jesus Christ; grounded upon the Scriptures, and confirmed by the practice of the Christian Church in all ages.' 4to. Oxf. 1644.

The season of the Nativity is no longer marked by that fervid hospitality which characterized its observance among our forefathers. At present Christmas meetings are chiefly confined to family parties. The wassail bowl, the yule-clog, and the lord of misrule, with a long train of sports and customs, which formerly prevailed at this season, are forgotten: even Christmas carols are nearly gone by: and the decking of churches, and of a few houses of people in humble life, with holly and other evergreens, forms now almost the only indication that this great festival is at hand. For the customs formerly prevalent, before, at, and about Christmas, see Brand's *Pop. Antiq.*, 4to edit., vol. i., pp. 350-415.

CHRISTMAS ROSE. [HELLEBORUS.]

CHRISTOPHE, HENRY, was born about 1767 or 1768. The place of his birth seems to be uncertain, for St. Christopher, St. Croix, St. Domingo, and Granada, are mentioned by different writers. He first attracted attention when a young man as a skilful cook at a tavern in Cape-Town, St. Domingo. In 1790, on the insurrection of the blacks in the French part of that island, he joined the insurgents, who paid great respect to his gigantic stature, energy, and courage. As the negroes succeeded he was promoted in military rank. Toussaint Louverture, the generalissimo of the blacks, employed him to put down an insurrection headed by Moise, or Moses, that general's own nephew. Christophe, by employing consummate artifice, got possession of Moses, who was put to death by his uncle, on which Christophe succeeded to his command in the northern province of French St. Domingo. He subsequently suppressed other revolts which troubled the dawn of negro freedom. In 1802, when General Leclerc, the brother-in-law of Napoleon Bonaparte, conducted a strong expedition from France to regain St. Domingo from the blacks, Christophe boldly defended Cape-Town; and when obliged to retreat, he burnt a great part of the town, and carried off 3000 men, with whom he joined Toussaint Louverture. When Toussaint was treacherously seized and transported to Europe, Christophe rallied with Dessalines, who then became commander-in-chief of the blacks. Through the effects of climate and a fierce desultory warfare, in which no one was more distinguished than Christophe, there was no longer any French force in the island by 1805. Dessalines then assumed supreme power in Hayti, and advanced Christophe. Not long afterwards Dessalines was accused of abuse of powers, and Christophe, joining with the mulatto Pethion, got up an insurrection, and murdered him in October, 1806. Christophe was then proclaimed generalissimo and president for life of the republic of Hayti, and he named his confederate Pethion his lieutenant and governor in the southern provinces. The negroes, imitating the republican proceedings of their old masters the French, had a national assembly of their own, which met at Cape-Town, and gave plausible grounds for Pethion, who was probably only jealous of his superior, to quarrel with Christophe. The mulatto general accused the president of a design against the liberties of the republic; the president called the general an anarchist and a revolted subject, and taking up arms drove him back to Port-au-Prince, where Pethion however maintained himself and what he called his republic for nearly eleven years.

In 1811 Christophe being undisputed master of the greater part of the country, had himself proclaimed king of Hayti, under the title of Henry I.; royalty, at the same time, being made hereditary in his family. Still following the fashions of Paris, he then organized a court and an hereditary nobility, creating black dukes, counts, barons, &c. On June 2, 1812, he was publicly crowned, and the ceremonies, all after the French pattern are said to have been very solemn and imposing. On the fall of Napoleon, the house of Bourbon entertained hopes of regaining their old colony, but they were frustrated by the power and skill of Christophe, who possessed several qualities that fitted him for government. On the death of Pethion, in 1818, he endeavoured to get possession of his state by force of arms, but he was beaten back with great loss by the republican blacks under their new president, General Boyer. These reverses, added to subsequent losses by fire, and other accidents, materially weakened him, at a moment when his tyranny and cruelty had rendered him generally unpopular at home, and the state of his health unfitted him for exertion. He was lying in bed from the consequences of an apoplectic stroke in Sans-Souci, a fine palace which he had built and fortified, when an insurrection burst around him, which had been aided by President Boyer. The insurgents had already proceeded to extreme measures, and the duke of Marmalade (a significant title), one of the first dignitaries of the kingdom, had proclaimed the abolition of monarchy. Seeing that nobles, generals, officers, and men, alike deserted him, to avoid being taken prisoner, Christophe shot himself through the heart on the 8th of October, 1820. His widow and children, with his favourite, General Noël, took refuge in Fort Henri, but the garrison presently surrendered, when his eldest son, Noël, and some inferior officers, were massacred.

During his reign, Christophe entertained some enlightened views. At one time he encouraged education, and the printing of books and newspapers. He even made a code of laws, which he called 'Code Henri', as Bonaparte had called his 'Code Napoléon.'

(*Amer. Cyc.*; *Biog. des Contem.*; Malo, *Hist. de Hayti.*)

CHRISTOPHER, DUKE of WURTEMBERG, was born in 1515. His early life was past in great troubles. In 1519-20 the confederated Suabian cities expelled his father Ulric from his dominions, and transferred the dukedom to the house of Austria. Christopher was carried to Vienna, where he narrowly escaped being made a prisoner by the Turks during their siege of that capital, under the great Solyman. In 1532 the Emperor Charles V. determined to confine him in a monastery in Spain, being more apprehensive of his talents than of those of his father the expelled duke, who was still living. When near to the Spanish frontier, Christopher escaped from his escort and fled to Bavaria, where his uncle, the reigning duke, and Philip the landgrave of Hesse, took up his own and his father's cause. The landgrave in particular made many efforts to recover for Duke Ulric his antient inheritance, but the Emperor Charles and his brother Ferdinand obstinately refused to relinquish so valuable a territory. Recourse was then had to arms. The French king, Francis I., secretly supplied large sums of money; and marching rapidly on Würtemberg, the landgrave in 1534 defeated the Austrians in the battle of Laufen, and restored Duke Ulric, who was well received by his people, and thenceforward placed under the safe protection of the great Protestant league of Schmalkalden. The recovery of Würtemberg was a great advantage on the side of the Protestants; but it was not until 1552, or two years after the death of Ulric and the accession of Christopher, that the Lutheran religion was fully established in that duchy. Finding, after a reign of two years, his authority was firmly established, Christopher proceeded to complete the work of the Reformation; and it is as a church reformer that he is honourably distinguished from the Protestant princes his contemporaries. He neither seized the church property for himself, nor distributed it among his nobles and courtiers. He appropriated it to the purposes of education, and to the support of the ministers of the new religion. A great fund was formed out of it and kept sacred, under the name of the 'Würtemberg church property;' the revenue derived from which sufficed to support what were called the Würtemberg cloister schools—destined for the education of the clergy—the great theological seminary at Tübingen, and other establishments for the instruction of the people. Christopher also extended the liberties of his subjects, and gave them a code of laws. After a popular and beneficial reign of eighteen years, he died in December, 1568

CHRISTOPHER, HERB. [Actæa.]

CHRISTOPHER'S, ST., or ST. KITT'S, one of the Caribean islands, was discovered by Columbus in November, 1493, who was so delighted with its appearance that he gave it his own Christian name. At this time it was well peopled by the Caribbs, by whom it was called Liamuiga, or the Fertile Island. It was never colonized by the Spaniards, but was the first of all the British settlements in the West Indies. A party under Mr. Thomas Warner took possession of it in 1623, and four years afterwards it was shared with some French settlers. After various bloody contentions, the island was wholly ceded to the English, in whose possession it remained till 1782, when it was taken by the French, but restored at the peace of 1783. In 1805 it was again ravaged by the French, who however did not retain possession.

St. Kitt's contains about 44,000 acres, nearly one half of which is unfit for cultivation. The other part is almost entirely occupied with plantations of sugar-cane, leaving only a small portion for cotton, indigo, pasturage, and provisions. The centre of the island is occupied by rugged barren mountains, which contain some hot springs. The highest point, called Mount Misery, 3711 feet above the sea, is an exhausted volcano, the crater of which is still apparent. The soil of the plains is chiefly a dark grey loam.

The island is divided into nine parishes, and contains four towns—Basseterre, Sandy Point, Old Road, and Deep Bay. Basseterre is considered the capital. Its shores are protected by several small batteries. It sends ten members to the House of Assembly at Antigua, of which government it forms a part. The climate, though hot, is considered healthy, but the island is subject to violent hurricanes. It lies N.W. and S.E., 17 miles in length and 6 in breadth, and is separated from Nevis by a strait only a mile and a half wide.

CHROMATIC. [Achromatic; Optics.]

CHROMATIC SCALE, in music, is the scale of semitones [Scale]; and by *chromatic music* is commonly signified that kind of harmony in which extreme intervals are much used.

In the Greek music the *chromatic* (from *χρῶμα, colour*) was the second of the three *genera*, and, according to the opinion of some, was so denominated because the notes, or musical characters, in that genus were written in colours. Others think that the word was figuratively employed, and expressed a greater variety of shade, more of contrast, than the other *genera*. Having no data to judge from, it is impossible to say which of the two opinions is the correct one; and, in truth, the question may just as well remain in its present state.

CHROMIC ACID. [Chromium.]

CHROMIS, a genus of fishes. [Labridæ.]

CHROMIUM, a metal discovered by Vauquelin [Vauquelin], a distinguished French chemist, in the year 1797. He found it in a rare Siberian mineral, which contained lead, and called, from its colour, *red lead*, but which is now known as *chromate of lead*. Previous but very imperfect attempts had been made to determine the nature of this substance. Vauquelin proceeded in the following manner: he boiled 100 parts of the ore in a solution of 300 parts of bicarbonate of potash; after long ebullition it was found that 22 parts of the mineral were dissolved; the 78 remaining were boiled in diluted nitric acid, which dissolved 64 and left 14 parts; these, again treated with carbonate of potash, left only 2 parts, which, being red lead, were neglected. The nitric solution being evaporated yielded a crystallized nitrate of lead, which being converted into sulphate gave such a quantity of it as indicated 56·68 of metallic lead.

The alkaline liquors being mixed and evaporated, yellow crystals were procured; these, dissolved in water, and treated with dilute nitric acid, yielded, by spontaneous evaporation, crystals, which were the acid of the new metal, and to which Vauquelin gave the name of *chrome*, from its property of colouring the compounds into which it enters; and he concluded from his analysis that the Siberian red lead consisted of nearly

Chromic acid	34·88
Oxide of lead	65·12
	100

When this chromic acid, or, better, the oxide of chromium presently to be described, is mixed with charcoal in a crucible and very strongly heated, it is decomposed; this however is effected with difficulty on account of the great affinity of the metal for oxygen, and also of the high temperature requisite to fuse the metal; this is indeed so great that it cannot be obtained in a button or one mass, but is pulverulent, of a yellowish white colour, and metallic lustre. Its specific gravity is generally stated at 5·9, but according to Dr. Thomson it is but little above 5. The appearance of the metal varies however according to the circumstances under which it is reduced; thus Liebig obtained it as a black powder, by acting upon one of its chlorides with ammonia; from another chloride and ammoniacal gas it was obtained of a chocolate brown colour, and so finely divided that when heated in the air it burnt.

Chromium suffers but little change by exposure to the air; it conducts electricity. Acids act upon it but slightly, the nitric even dissolving it only after long ebullition; nor is the solution readily effected even when hydrochloric acid is added to the nitric so as to produce nascent chlorine: hydrofluoric acid when heated dissolves it, and hydrogen gas is evolved: heat acts but little upon this metal; even the flame of the blowpipe scarcely affects it.

Before describing the various compounds which this metal forms with different elementary bodies, or the nature of the more complex combinations of which it forms a part, it will be proper to describe the various ores which have been met with since its original discovery in the Siberian red lead, beginning however with a description of that substance.

Ores containing Chromium.

Chromate of Lead. Red Lead. Occurs massive and crystallized. Primary form of the crystal, an oblique rhombic prism. Colour, deep orange-red. Lustre, adamantine; sometimes translucent, rarely transparent. Specific gravity, 6. Hardness, 2·5, 3. Brittle; streak, orange-yellow. Cross-fracture, uneven, passing into conchoidal, with a splendent lustre. With the blowpipe, crackles and melts into a greyish slag. Soluble in nitric acid, solution yellow. Occurs in the gold mine of Berezof in Siberia, in the Ural, and Brazil.

When pure it is composed of

Chromic acid	31·71
Oxide of lead	68·29
	100

Massive varieties, amorphous; structure columnar, granular.

Subsesquichromate of Lead. Monochroite. Occurs massive and crystallized; form of the crystal imperfectly described. Colour, red. Lustre, resinous. Translucent on the edges. Specific gravity, 5·75, very soft. Powder, tile-red. Fuses by the blowpipe into a dark mass. Occurs with chromate of lead in the Ural. It is composed of

Chromic acid	23·31
Oxide of lead	76·69
	100

Chromate of Lead and Copper. Vauquelinite. Occurs massive, and in minute crystals. Primary form, an oblique rhombic prism. Colour, black or greenish-black. Lustre, adamantine, nearly opaque. Specific gravity, 5·5 to 5·78. Hardness, 2·5, 3. Streak, greenish. Fracture, uneven.

Before the blowpipe, fuses into a dark grey globule of metallic lustre, surrounded with beads of metallic lead.

The massive varieties are amorphous, botryoidal, reniform. Structure compact, fine granular.

Found with chromate of lead in Siberia.

Composed of, according to Berzelius,

Chromic acid	28·33
Oxide of lead	60·87
Oxide of copper . . .	10·8
	100

Chromate of iron. Chromiron—occurs massive and crystallized; crystal, the regular octahedron; colour, blackish; lustre, imperfect metallic; opaque; hardness, 5·5; brittle;

specific gravity, 4·321; streak, brown; fracture uneven, imperfect conchoidal; not attracted by the magnet; cleaves parallel to all its planes.

Analysis of the crystals from Baltimore, by Dr. Thomson:

Green oxide of chromium . .	52·95
Peroxide of iron	29·24
Alumina	12·22
White matter	3·09
Water	0·70
A trace of silica	
	98·20

The massive is amorphous, with a granular or compact structure; it is found in the island of Unst, in Scotland, and sometimes interspersed with green oxide: it occurs also in France and in North America, especially near Baltimore. Oxide of chromium has been observed in some aërolites.

We proceed now to the binary compounds of chromium, and first those which result from the combination of

Oxygen and Chromium.

1. *Chromic acid* may be prepared in several ways; one of the best is to dissolve bichromate of potash in water, and to pass through the hot solution hydrofluate of silica, which combines and forms a difficultly soluble salt with the potash, and the chromic acid remains in solution: this is to be evaporated to dryness in a platinum capsule, and the residue dissolved in a very small quantity of water: this solution, when further concentrated by evaporation, deposits red crystals of chromic acid, which are deliquescent, and very soluble in water. The solution is devoid of smell, but has a sour styptic taste; the solution is red or yellow, according to the degree of concentration: this acid is also very soluble in alcohol, and when the solution is heated it is decomposed, the results being oxide of chromium, formic acid, and æther. It acts upon and destroys vegetable colouring matter, and combines with bases to form salts, called chromates.

According to Berzelius, chromic acid is composed of

3 equivalents of oxygen . . .	24
1 „ „ chromium . . .	28
Equivalent	52

2. *Oxide of chromium*, or rather *sesquioxide of chromium*, may be prepared in several modes, almost all of which are dependent upon the partial deoxidizement of chromic acid; thus when chromate of potash is mixed with its own weight of muriate of ammonia, and heated to redness, oxide of chromium is left, being formed by the deoxidizement of the acid by the hydrogen of the ammonia. Alcohol, sugar, sulphur, protonitrate of mercury, and oxalic acid, produce corresponding effects. The properties of this oxide are, that it has a green colour, it is insoluble in water, and unchanged by heat: the alkalis do not act upon it, but it is soluble in acids, forming salts with them. When combined with water so as to form a hydrate, it is of a bluish tint, and is then more readily dissolved by acids than after it has lost its water by a red heat.

It is the colouring matter of the emerald.

It is composed of

1½ equivalent of oxygen	12
1 „ „ chromium . . .	28
	40

A brown oxide of chromium has been supposed to exist, but it is probably a mixture of the acid and green oxide.

Azote and *hydrogen* do not combine with chromium.

Chlorine and *chromium* combine in two proportions: the sesquichloride may be prepared by dissolving the sesquioxide in hydrochloric acid, and evaporating the solution to dryness at 212°; a green residue is obtained, which consists of the sesquichloride combined with water; when this is heated to about 400°; the water is expelled, and the pure sesquichloride remains of a reddish colour, when the operation is so conducted as to prevent the access of carbonic acid: when strongly heated in a close vessel it sublimes in scales of a peach blossom colour. This compound is readily soluble in water; the solution is green, and remarkable for the sweetness of its taste.

It is composed of

1½ equivalent of chlorine . . .	54
1 „ „ chromium . . .	28
	82

Terchloride of chromium is prepared by heating a mixture of chromate of potash, fused chloride of sodium, and sulphuric acid in a glass retort. By their mutual action a red vapour is evolved, which, passed into a cooled receiver, condenses into a fluid of a fine red colour. By water it is immediately decomposed, and yields a mixture of chromic and hydrochloric acids. It is composed of

3 equivalents of chlorine	108
1 „ chromium	28
	136

Fluorine and chromium form two compounds: the *Sesquifluoride* is procured by dissolving oxide of chromium in hydrofluoric acid; by their mutual decomposition and evaporation to dryness, water and the sesquifluoride are formed, and the latter remains as a green powder, which is soluble in water and composed of

1½ equivalent of fluorine	28·5
1 „ chromium	28
Equivalent	56·5

Terfluoride of chromium is prepared by distilling a mixture of chromate of lead, fluor spar, and sulphuric acid in a leaden retort. A red coloured gas comes over, which acts rapidly on glass, and is decomposed by water, with the formation of chromic and hydrofluoric acids. It is composed of

3 equivalents of fluorine	57
1 „ chromium	28
Equivalent	85

Bromine and chromium form two bromides, which are stated to be sesquibromides and terbromides. They are unimportant compounds.

The *non-metallic solids*, or at least several of them, combine with chromium; but this is not the case with carbon.

Sulphur and chromium may be made to combine, though not by direct action, in several different modes; the simplest is to heat the hydrate intimately mixed with sulphur in a close vessel; this sulphuret is of a dark grey colour, unctuous to the touch like plumbago, and when slightly heated in the air it burns like a pyrophorus, and is converted into oxide of chromium and sulphurous acid gas. It is not acted upon by nitric acid, but nascent chlorine dissolves it. It is a sesquisulphuret, composed of

1½ equivalent of sulphur	24
1 „ chromium	28
Equivalent	52

Phosphorus and chromium form phosphuret of chromium. It is prepared by acting on the sesquichloride by phosphuretted hydrogen. It is black, insoluble in hydrochloric acid, and but slightly acted upon by nitric acid or nascent chlorine. It is composed of

1 equivalent of phosphorus	16
1 „ chromium	28
Equivalent	44

The *salts of chromium* are next to be noticed. There is perhaps no metallic substance which so perfectly acts as an acid to bases and as a base to acids as this metal; the difference depending, of course, upon its degree of oxidizement, that is, whether it be an acid or an oxide. The compounds of the chromic acid and bases will first be mentioned, or the chromates.

Chromate of potash. This salt is used in large quantity, and is prepared by reducing chromiron to powder, mixing it with nitre, and subjecting the mixture to a high temperature in a crucible. The nitric acid of the nitre is decomposed, its oxygen acidifies the oxide of chromium of the chromiron, and this uniting with the potash of the nitre, forms chromate of potash, which is washed out from the residue of peroxide of iron, and the solution is evaporated and crystallized.

The crystals of chromate of potash are yellow; the primary form is a right rhombic prism. It has a bitter disagreeable taste, is soluble in about twice its weight of water at 60°, and much more so in boiling water; it is insoluble in alcohol, and unalterable in the air; it turns turmeric paper reddish brown, but is a neutral salt, composed of

1 equivalent of chromic acid		52
1 „	potash	48
		100

Bichromate of potash may be prepared by adding chromic acid to a solution of the chromate, but it is more economically obtained by adding nitric acid. By evaporation crystals of bichromate are obtained; the primary form is a doubly oblique prism, and they are frequently large. Bichromate of potash has a penetrating, bitter, metallic taste; and is not alterable by exposure either to air or moderate heat. It is soluble in about ten times its weight of water at 60°, and more so in boiling water: the solution reddens litmus paper. When heated to whiteness, half of its acid is decomposed into oxide of chromium of a very fine colour, mixed with chromate. It is decomposed, as already noticed, by various deoxidizing bodies, such as alcohol, sugar, &c. It is composed of

2 equivalents of chromic acid		104
1 „	potash	48
Equivalent		152

It contains no water.

Chromate of soda and bichromate of soda are salts analogous to those of potash just described. The former is yellow, and so very soluble that the least increase of temperature causes it to fuse in its water of crystallization. The bichromate is red.

Chromate of lime is soluble in water, and crystallizes in silky plates.

Chromate of magnesia. The neutral chromate is yellow; it is very soluble, and crystallizes in prisms. The bichromate is red.

Chromate of barytes. It is prepared by the double decomposition of chromate of potash and nitrate of barytes. It is of a yellow colour, insoluble in water. It is decomposed by sulphuric acid, which throws down the barytes in the state of sulphate, and a compound of sulphuric and chromic acids remains in solution. Hydrochloric acid converts it into chlorides of chromium and barium. It is composed of

1 equivalent of chromic acid		52
1 „	barytes	76
Equivalent		128

Chromate of chromium. This compound is obtained by dissolving hydrate of chromium in chromic acid; the solution is of a brown colour; by evaporation a solid uncrystallized mass is obtained, which attracts moisture from the air, and dissolves readily in water and in alcohol. It is a bichromate, composed of

2 equivalents of chromic acid		104
1 „	sesquioxide of chromium	40
Equivalent		144

Bichromate of iron is prepared by saturating the acid with perhydrate of iron. The solution is decomposed by water, which precipitates peroxide of iron, and holds the chromic acid in solution. It appears to be a bichromate, composed of

2 equivalents of chromic acid		104
1 „	peroxide of iron	40
Equivalent		144

Chromate of manganese is obtained by dissolving the carbonate of manganese in chromic acid. The solution is brown, and has a sharp metallic taste. It is decomposed by evaporation, and yields no crystals.

The above described metallic chromates are unimportant, but the chromate of lead is a compound, which is extensively employed as a pigment and in calico printing.

As a pigment it is prepared by the double decomposition of chromate of potash and nitrate of lead. The precipitate is of a fine yellow colour, totally insoluble in water, but dissolved by nitric acid; and it mixes well with oil. It is composed of

1 equivalent of chromic acid		52
1 „	oxide of lead	112
Equivalent		164

It is also used in calico printing.

Dichromate of lead is prepared by digesting the chromate in solution of potash; this removes half the chromic acid, and the remaining salt is of a fine scarlet colour, insoluble in water; when heated it becomes brick red, but its scarlet colour returns as it cools; by the addition of nitric acid it is reconverted to neutral yellow chromate. It consists of

1 equivalent of chromic acid		52
2 „	oxide of lead	224
Equivalent		276

These are the most important chromates; the salts which contain oxide of chromine as a base are not at all employed: we shall mention only the most distinctly marked of them.

Nitrate of chromium. Oxide of chromium dissolves readily in nitric acid; it is however difficult to saturate it. The solution when evaporated to dryness leaves a reddish substance, which dissolves easily in water. It does not appear to yield crystals, nor has its composition been ascertained; it is however probably a neutral nitrate.

Sulphate of chromium is prepared by dissolving the hydrate in dilute sulphuric acid; the solution is of a dark green colour, and has a sweetish taste. By evaporation to dryness a dark-coloured tasteless matter remains, which is not altered by exposure to the air, and does not readily dissolve in water. It is probably a neutral sulphate.

The arseniate, carbonate, and phosphate of chromium are all insoluble compounds, which are not at all employed, nor indeed is any salt of oxide of chromium; but, as already noticed, the chromates of potash and lead are largely used, and oxide of chromium is employed to give a green colour to glass and to porcelain.

CHRONICLE, CHRO'NICON (from χρόνος, time), denotes a history in which facts are digested in order of time, though not necessarily in successive years, as is distinctly implied in the word Annals. It must be owned however that the two terms have been indiscriminately used for histories in which the succession of years has been the governing principle of the narrative. The term Chronicle, at the present day, is seldom used but in speaking of our old histories, as the 'Saxon Chronicle;' 'Caxton's Chronicle;' 'Fabyan's Chronicle;' 'Holinshed's Chronicle;' &c. This term was also adopted by the French, as in 'Les Chroniques de France (appellee la Chronique de St. Denys), compiles par l'ordre du Roy Charles VIII.,' 3 tom., fol. Par. 1476 [ANNALS.]

CHRONICLES, the name of two books of the Old Testament. In the original Hebrew they constitute only one book, entitled דִּבְרֵי הַיָּמִים (Debri Haimim) *Verba Dierum*, Words of Days; that is, diaries or journals. In the Septuagint they are called *Παραλειπόμενα, res prætermissæ*, 'things omitted.' The Books of Chronicles have been so called from being considered as supplementary to the Books of Samuel and of Kings; the histories of which they repeat with considerable variations. Some commentators and critics state decidedly that the compiler is unknown. (Vatablus, Hoffmann.) The name Chronicles seems to have been first applied by St. Hieronymus (Jerome), who is followed by Du Pin, Bishop Patrick, and most modern commentators, in supposing that Ezra, otherwise Esdras, was the compiler of these books, about twenty-six years after he compiled the Books of Kings, and eighteen after the return of the Jews from the seventy years' captivity in Babylon. (Dr. Allix, *Reflex. on Old Test.*, vol. ii., c. 1.) Eichhorn enumerates several reasons for attributing them to Ezra (*Einleitung*, vol. ii., pp. 579—601), the chief of which is, a similarity to the Books of Kings and Ezra in style, orthography, and idiom. The Jews also ascribe them to Ezra. There are however several considerations which diminish the probability of their being his work (Calmet's *Dict.*, by Taylor), one of which is, that (*Chron.* iii. 19, et seq.) an account is given of the posterity of his contemporary Zerubbabel, which extends several generations beyond the time of Ezra, who is supposed to have died at the age of 120, a year or two after compiling the Chronicles (Ezra, in Taylor's Calmet); but nothing, as Eichhorn observes, is certainly known of the time either of his birth or his death. The apparent improbability that the histories of the Books of Kings should be re-written by the same person with such numerous discrepancies and contradictions as are found between Kings and Chronicles, is thus explained by the commentators: they state that Ezra, on his return to Judæa, discovered more and better materials than he possessed when he compiled the Books of Kings at Babylon, and therefore the Chronicles are to be regarded as *addenda* and *corrigenda*. Some however of the variations are not improvements: for example, in the history of Jehoram (2 Chron. xxi.), which is repeated verbatim from 2 Kings viii. 17, &c., this king is said (v. 5 and 20) to have died at the age of 40, as related in Kings; but the probable statement in Kings (v. 26) that his son Ahaziah's age, on succeeding him, was 22, is altered in Chronicles to 42 (ch. xxii. 2), making the son two years older than the father. It stands thus in the authorized version, but in some antient MSS. of Chronicles it is written 22. The numerous contradictions throughout Chronicles and Kings, in facts, dates, numbers, names, and genealogies, are acknowledged by many learned critics. They form the subject matter of nearly the whole of Dr. Kennicott's First Dissertation on the State of the Hebrew Text; where they are treated as corruptions, interpolations, and mistakes. In the narrative 1 Chron. xviii. 3, which is taken verbatim from 2 Sam. viii. 3, there occurs, besides a variation of proper names, an alteration of 700 horsemen to 7000: and exactly 'the same mistake' (Kennicott) occurs in the passage cited in 1 Chron. xix. 18, from 2 Sam. x. 8. Compare also the numbers in 1 Kings iv. 26, with 2 Chron. ix. 25; and 1 Kings ix. 23, with 2 Chron. viii. 18. Many passages and chapters in Chronicles and Kings appear to have been transcribed verbatim from records made before the Babylonian captivity, while the Temple was standing: as 2 Chron. v.; and 1 Kings viii., which are word for word alike, and speak of the ark, the former in v. 9; the latter in v. 8, as being in the Holy Place 'unto this day:' though neither Kings nor Chronicles are supposed to have been written until from sixty to ninety years after the Temple, and all its contents had been demolished, or carried off by Nebuchadnezzar. Another instance is in 2 Chron. viii. 8. In fact, the compiler or abridger appears to have had before him a collection of various antient memoirs, genealogies, annals, registers, &c., from which he quoted indiscriminately 'without taking the trouble to reconcile inconsistencies.' (Rees's *Cyclopædia*; *Theolog. Dict.*, by J. Robinson, D.D.) The last thirteen verses of 1 Chron. ch. i., occur verbatim in Genesis, ch. xxxvi., and appear to have been transcribed from some historical document made after Saul, the first king, reigned in Israel (see v. 31), which was 400 years after the death of Moses. Another curious particular is that the two last verses of 2 Chron. concerning the proclamation of Cyrus, are the same which begin the following Books of Ezra. In Rees's *Cyclopædia*, this fact is accounted for in the following words:—'Some transcriber having finished Chronicles at v. 21, proceeded, without leaving the usual space, to write the Book of Ezra; but finding his mistake he broke off abruptly, and began Ezra at the usual distance, without indicating his error by erasing the passages which he had carelessly subjoined to Chronicles.' The broken sentence with which Chronicles end at 'go up,' is completed in v. 3 of Ezra 'to Jerusalem,' &c. Grotius, in his Comment. on Chron. says, 'Is mos libros continuandi est antiquus, quem et Procopius sequitur fine Vandalicorum et Gothicorum initio.' (*Opera Omnia*, tom. i., p. 189.)

To this suggestion may be added a fact not noticed by the commentators, that the Jews, in the public reading of their scriptures, to avoid ending with the recital of any calamity producing dejection, add the commencement of the next paragraph, or repeat a portion of that which precedes, in order to finish with something consolatory. Accordingly, in Hebrew copies, at the end especially of Isaiah, Malachi, Lamentations, and Ecclesiastes, a masoretic sign is given, formed of the initials of these four books (יתקק) to indicate the recital of some antecedent or subsequent passage. It is supposed by St. Hieronymus that the present books of Chronicles are those of the kings of Judah and of Israel, so often referred to in the books of Kings. The objection to this supposition is, that these references are not unfrequently made to what is not to be found in the present book of Chronicles. The Chronicles referred to in Kings are generally thought to have been a voluminous work from which ours are only a brief and mutilated abstract. Grotius, Capellus, Spinosa, Clericus, R. Simonius, Whiston, and others, hold this opinion. Carpzof, in his 'Introduc. ad Vet. Testament,' rejects it as 'very absurd.' The chief design of this compilation seems to have been to exhibit, first, the genealogies, ranks, and functions of the priesthood, in order that, after returning from the captivity, they might re-assume their proper dignities: and secondly, by describing the distribution of lands before the Captivity, to direct the families of each tribe in regaining their antient inheritances. The first book is a recapitulation of sacred history from the creation to the death of David. The second book gives the history of the kings of Israel and Judah from Solomon, to the return from Babylon. Jerome attaches a great importance to the study of these books his words are, 'The book of things omitted (the book of Chronicles), i. e., an epitome of the Old Testament, is of such great importance, that if a man lay claim to a knowledge of scripture without knowing this book, he is only deceiving himself; for every single name, and every juxtaposition of words, both refer to innumerable things omitted in the Books of Kings, and explain innumerable difficulties in the Gospel' (Hieronymi *Opera*, 1734, tom. i., p. 277); and in his preface 'ad Lib. Paralip.,' he says, 'This work contains all the learning of the Scriptures.' The same father enjoins a young friend (*Epist. 7 ad Leta.*), to learn by heart the whole of the two Books of Chronicles, together with the Pentateuch, Prophets, Kings, Esdras, Esther, and Solomon's Song. The authority of the books of Chronicles is established by St. Paul's applying a prophetic passage (Heb. i. 5) to the character of our Saviour from 1 Chron. xvii. 13 and 14; see also chap. xxii. 10.' (Bishop Mant's *Bible.*) For the purpose of comparison and critical investigation, see the table of Chronicles, Samuel, and Kings, in Horne's 'Introduction to the Bible,' vol. iv., p. 58, and vol. ii., p. 37: also Cruttwell's 'Concordance of Parallels,' p. 147. A notice of the Commentators on the books of Chronicles—Hieronymus, Procopius, Bede, Crommius, Lavater, Leonhartus, Sanctius, Serarius, Strigelius, Jackson, &c., may be found in Jo Gotlobb. Carpzovii 'Introduc. ad libros Canonicos,' 4to., 1731, tom. i., pp. 279–303, and tom. ii., pp. 466–487: in William Crowe's 'Catalogue of Commentators,' 12mo., 1668, pp. 46–49, and in Hoffmanni 'Lexicon.' See also 'Poli Synopsis Criticorum,' fol., vol. i., p. 714, et seq.; Bishop Patrick's 'Comment.,' vol. ii., p. 529; Du Pin 'Compleat Hist. of the Canon.,' fol., p. 84. Eichhorn, 'Einleitung in das Alte Testament,' ubi supra; Kennicott's 'Dissertation,' and 'Reply' to it, by Julius Bates, pp. 104—185; and the Abbé Richard's critical treatise on the apparent contradictions of Chronicles and Kings.

CHRONOLOGY (*χρονολογία*), a Greek word, literally signifying 'time-reckoning.' In contradistinction to history, which connects events according to the manner in which each is produced or occasioned by another, chronology regards events simply according to the order of time. It is evident however that the succession of events in the order of time makes a very important part of their exposition in the relation of cause and effect; for whatever else there may be in the bond which unites what we call a cause and its effect, the circumstance that the cause precedes the effect in the order of time is always present. A history therefore cannot be written even in the loosest manner, nor an intelligible narrative put together, without chronology being so far attended to that the events shall be related in the order in which they happened. Even what is called the epic method of taking up the story in the thick of the interest, rather than from the beginning of the series of events out of which the interest grows, is no exception. In whatever mode it may be thought best for the effect intended to be produced that the several portions of the story should be arranged and exhibited, each portion must in itself be detailed chronologically, else it will be incomprehensible And even in an epic poem an order of time is always strictly observed throughout, though the poet may select a different series of events through which to take his course from that which would be adopted by the historian. In the Æneid, for example, it is true that the events of the shipwreck of Æneas and his followers, and their reception by Queen Dido, which are related in the first book of the poem, happened subsequently to the destruction of Troy, and their adventures in the course of their navigation to Carthage, which pass before the reader in the second and third books; but these last mentioned events are really not what the poet professes to relate in these two books. What they profess to contain is the discourse addressed by Æneas to Dido, at the banquet in her palace; and the delivery of this discourse happened not before but after the events related in the first book of the poem.

The order of a history, however, will often differ from that of a purely chronological arrangement in this respect. In the former each connected series of events is related separately, and thus forms a unity, in which the progress and development of certain principles, causes, or given conditions of society are exhibited. In the latter, events of various naturally distinct series are necessarily intermixed, nothing being attended to except the order of time in which they happened. Thus a mere chronological table, or chronicle, of the events of the last century would enumerate, under no arrangement except the order of time, the events which had taken place during that period in all the countries of the world, and in all the departments of human action, and also it might be of inanimate nature; if the scheme were comprehensive enough, the notice of an inundation of the ocean, or an eruption of Vesuvius, might break in upon the detail of a succession of scientific discoveries, or the incidents of a political revolution. History, in the pursuit of its proper business of tracing each effect to its cause, necessarily avoids this intermixture. It first follows one chain of events, at least up to a certain point at which a pause may conveniently be made, and then it takes up another chain. Still each chain is continued in the chronological order of its links. Every long history, indeed, must in this way be properly a collection of many short histories; and these latter will be numerous in proportion to the extent and complexity of the subject. Neither a history nor a chronicle need embrace all the recorded or remarkable events of the period over which it professes to extend; the one as well as the other may be confined to events or transactions of any particular kind, as well as of any particular period. But whatever variety of matters may be comprehended in a history, it is at the option of the historian, and belongs to his art, to dispose them into as many distinct narratives, or portions of a narrative, as may appear best suited for their clear and effective exposition; whereas all the facts, however various, which a chronicle or chronological table may comprehend, must be related in one narrative or series. Though an intermixture of all kinds of events with those that more peculiarly belong to chronology, which are the events of political society, is not unusual in tables of chronology, the events of any one branch of human action or speculation, or, as already observed, the phenomena of nature, might often with more propriety be exhibited in separate chronological tables.

It has sometimes been attempted to combine in a chronological table, with its own peculiar advantages, something of this distinctness or separation of one subject from another which is found in a history, by employing a particular form of type or other appropriated mark for each series of connected events. This method was first employed, as far as we know, and indeed it is there claimed as new, in a short general chronological table at the end of the work entitled 'Elements of General History,' by Alexander Fraser Tytler (afterwards Lord Woodhouselee), 2 vols., 8vo., Edinburgh, 1801. In this table the series of the kings and emperors of Rome is printed in a larger Roman type than the rest of the table, that of the emperors of Germany in Italic capitals, that of the kings of England in the old English letter, that of the kings of France in small Italics, &c. 'By this method,' to quote the explanation of the compiler, 'the succession of the sovereigns in the different kingdoms is immediately distinguishable to the eye, as well as the duration of their reigns, while the intervening space is filled by the remarkable events that occurred at that period all over the world; and thus the connexion of general history is preserved unbroken.'

Some histories are written in a more, some in a less strict chronological order. It is observed by Dionysius of Halicarnassus, in a comparison between Herodotus and Thucydides, that Thucydides has followed the order of time, Herodotus that of things, and that on this account Thucydides is obscure and difficult to understand. While Thucydides, he says, has divided his single subject into many parts, Herodotus, having in his history embraced many different subjects, has formed them into a single whole, of which the several parts perfectly correspond. But though the method of Herodotus may be the best adapted for conveying a clear view of each particular portion of history of which he has treated, every series of naturally connected events forming a narrative or story by itself, it is not easy to gather from his work any notion of the synchronism of events, or of the relation of those of one series to those of another in point of time. Larcher, in the preface to his French translation of Herodotus (edition of 1802), has noticed that Photius has complained of the confusion occasioned by the digressions of this author, and that other critics have been disposed to deny that he followed any regular or intelligible plan. Larcher however dissents from this judgment, and explains what he conceives to have been the plan of Herodotus (*Preface*, pp. xxv.—xxxii.). He has also printed, with annotations, in his sixth volume, three memoirs by the Abbé Geinoz, in vindication of Herodotus against the attacks of Plutarch; and of these the third (pp. 601—627) is an exposition of the method and plan of the historian. His history is of the form of an epic poem, of which the main subject is the wars of the Greeks and Persians. The digressions, which correspond to the episodes of an epic poem, and, as in the case of that on Egypt, take up an entire book, render it very difficult for a young student to form an idea of the history as a whole. But if the episodes are cut out, the whole history exhibits the main subject in a regular progress and order. The chronological system of Herodotus has been amply illustrated by Larcher in his 'Essai de Chronologie sur Hérodote,' printed in the sixth volume of his first edition (1786), and, greatly altered and enlarged, in the seventh volume of his second edition.

But although both Herodotus and Thucydides have, each after his own method, so far adhered to a chronological arrangement as to relate the events in the order of time in which they happened, neither of these writers has throughout his narrative attended to chronology in any scientific sense. They were both prevented from doing this by the want, in that early age, of any fixed epoch or starting point from which to reckon. It has been well observed, that 'the best simile for dates is to say, that they are to history what the latitude and longitude are to navigation—fixing the exact position of, and serving as unerring guides to, the object to which they are applied.' (Nicolas's *Chronology of History, Preface*, p. vi.) In this view the histories of Herodotus and Thucydides may be compared to charts or maps drawn without the aid of parallels of latitude or meridian lines, in which indeed the situations of cities and mountains, the courses of rivers, and the general form of countries and outline of coasts might be represented with a certain degree of correctness, but not with the precision requisite for any scientific purpose. Thucydides, however, in recording the events of the Peloponnesian war, keeps to the order of the years; and he fixes the date of the commencement of the war (ii. 2), by referring to the truce made after the capture of Eubœa, to the priesthood of Chrysis in Argos, to the ephorship of Ainesias at Sparta, and the archonship of Pythodorus at Athens. In speaking of events that happened long before the war (i. 13, 19), he refers to the end of the Peloponnesian war as the point from which to reckon backwards.

The determination of the length of the year and the regulation of the calendar appear to have occupied the attention of the antients before they ever thought of dating events from a fixed epoch. But the latter object was of interest only to historical inquirers; the former matters were naturally in the hands of the cultivators of astronomy, who were the best qualified for their management, and were besides more immediately interesting and important to the whole community. There is a curious passage in the 'Clouds' of Aristophanes, in which the clouds, addressing the people of Athens, report a complaint made by the moon about the displeasure she had incurred from the gods in consequence of the confusion into which their festival days had fallen; the allusion, it has been supposed, being to Meton's reformation of the calendar, which had recently been introduced. (*Clouds*, 603, &c.) Aristophanes was a contemporary of Thucydides.

The first æra, or computation of time from an epoch, made use of among the Greeks was that of the Olympiads. 'Hail, venerable Olympiads, ye guardians of time, ye vindicators of the truth of history, ye bridlers in of the fanatical licence of chronologists!' exclaims Joseph Scaliger in his Animadversions on Eusebius, in a paroxysm of chronological enthusiasm. The date of the original institution of the Olympic games is placed in very remote antiquity; but it was a long time even after their revival by king Iphitus (B.C. 884) before they came to be used for the purpose of fixing historical events. The following paragraph is from the introduction to Playfair's Chronology, with the exception of the dates within brackets: 'Hellanicus (B.C. 496—411) regulated his narration by the succession of the priestesses of Juno at Argos. Ephorus (B.C. 300) digested things by generations. The Arundelian marbles (B.C. 263) make no mention of olympiads, and reckon backwards from the time then present by years. In the histories of Herodotus (B.C. 484—413) and Thucydides (B.C. 471—391) the dates of events are not ascertained by any fixed epochs. The olympiads were not commonly applied to this purpose in so early a period. Timæus of Sicily, who flourished in the reign of Ptolemy Philadelphus (B.C. 283—245), was the first who attempted to establish an æra, by comparing and correcting the dates of the olympiads, the Spartan kings, the archons of Athens, and the priestesses of Juno. Eratosthenes (B.C. 194), the father of chronology, and Apollodorus (B.C. 115) digested the events recorded by them, according to the olympiads and the succession of Spartan kings.' When the olympiads were adopted as an æra, the reckoning was made to commence from the games at which Corœbus was the victor, being the first at which the name of the victor was recorded. The olympiad of Corœbus accordingly is considered in chronology as the first olympiad. Its date is placed 108 years after the restoration of the games by Iphitus, and is calculated to correspond with the year B.C. 776.

The statement we have just quoted from Playfair is given at greater length, and with references to the authorities, in the first chapter of Sir Isaac Newton's Chronology. Of the names that have been mentioned, only Eratosthenes and Apollodorus can be considered as having been systematizing chronologers, or as having employed themselves on the science of chronology. The merits of Timæus appear to have consisted in his endeavouring to ascertain with greater precision than any preceding historian the dates of the events of which he treated in his histories of Sicily, of the wars of Pyrrhus, &c. An account of his works is given in Clinton's 'Fasti Hellenici,' iii., 489—491. The fragments of Timæus have been collected by Goeller, in his work, 'De Situ et Origine Syracusanorum,' 8vo., Leipzig: 1818. Eratosthenes, the eminent astronomer, seems to have endeavoured to establish what may be called a system of chronology by ascertaining the dates of certain antient events, which might serve as fixed points from which to reckon all other events. We have no account however of the process by which he arrived at his conclusions. The fragments of his chronological as well as of his other writings, with the passages of the antient authors in which each is mentioned, and notes, have been published by Gottfr. Bernhardy in a small volume, entitled 'Eratosthenica,' 8vo., Berolini, 1822. The dates which he affixed to the principal events of antiquity are given from Clemens Alexandrinus, in Clinton, i., 124. Those of Apollodorus, who made some corrections on the system of Eratosthenes, are given in Clinton, i., 125, as preserved by Eusebius on the authority of Porphyry. Clinton has shown that the leading dates of Eratosthenes and Apollodorus were adopted generally by subsequent chronologers, both Greek and Latin. Among the Romans the most eminent authority in chronology was Varro, who flourished in the century immediately preceding our æra, but of whose numerous and learned works very little remains. Belonging to a much later age, the third century of our æra, there has been preserved the work of Censorinus, entitled 'De Die Natali,' which is in the greater part a treatise on dates, epochs, and other matters appertaining to the science of chronology. There is a passage in the twenty-first chapter of Censorinus, containing a memorandum of the distance of the year in which he wrote (A.D. 238) from the first olympiad, from the building of Rome, from the reformation of the calendar by Julius Cæsar, and from other epochs, which has been thought so important to chronology, that Petau has attributed its preservation to the special goodness of Providence.

The establishment of the first olympiad as a common epoch may be said to have given birth to chronology as a science, by introducing into historical writing the general practice of dating events with reference either to that or to some other fixed point. The principal business of chronologers after this was to determine the relationship of each of these epochs to every other.

The common æra of the Roman historians commences from the foundation of the city of Rome. But there was a great variety of opinion among the antients, as there has continued to be among the moderns, respecting the true date of this event. The Romans themselves for the most part followed either the computation of Cato, which places it in B.C. 752, or that of Varro, which assigns it to B.C. 753. Some writers, among others Livy, appear to reckon sometimes by the one, sometimes by the other: most modern chronologers follow that of Varro. This practice of dating events from the building of Rome may be regarded as the first adoption of the simple method of reckoning from a fixed point by single years, and as forming therefore one of the great stages of chronology.

Another usual mode of reckoning among the Latin historians was by the annual consulships. Often both the year of the city and the names of the consuls are given.

The method of reckoning from the first olympiad was occasionally employed long after the birth of Christ. 'Some writers,' says Playfair, 'have continued the use of the olympiads to the 312th year of the Christian era. Cedrenus (a Greek monk of the eleventh century) has brought them 80 years lower, making the 393rd year of our Lord the last olympian year.' Sir Harris Nicolas (*Chronology of History*, p. 2) speaks of the computation by olympiads having ceased after the 364th olympiad, in the year of Christ 440. Particular writers may have reckoned by olympiads down to that date, as they might down to the present day; but it had certainly long before ceased to be the common practice to do so. From A.D. 312 the regular public mode of computation throughout the Roman empire, both west and east, was by the indictions, which were cycles or periods of fifteen years, beginning with that year. [INDICTION.] The practice of dating events by indictions was at one time followed in most of the kingdoms of modern Europe, and in France was not altogether discontinued till the end of the fifteenth century. The method of dating events from the birth of Christ is said to have been first practised by a Roman monk named Dionysius the Little about the year 527. It came into general use in Italy before the termination of that century, but in France not until the eighth century, in Spain not until the fourteenth, and in Portugal not till after the commencement of the fifteenth. The method of reckoning from this epoch, being now universally adopted throughout Christendom, and being the only computation generally used both in historical accounts of past events and in dating current time, has furnished a chronological measure of much more extensive application than any other which had preceded it. It is generally held that the birth of Christ actually took place about four years earlier than the date assigned to the event by Dionysius; but this mistake of the inventor of the vulgar æra does not affect its value as a scheme of chronological notation. It is quite unimportant which the point is from which we reckon, if it be a determinate point.

There is one inconvenience however attending the choice of an event for reckoning from so recent as the birth of Christ, namely, that it necessarily introduces two modes of reckoning, and leaves the events of a large, in fact of the largest, portion of history to be as it were dated backwards, or according to the distance of each behind the assumed epoch. Even the æra of the olympiads was not free from this objection; for although, as we learn from Censorinus, Varro considered the historical age to commence only with the first olympiad, the traditions even of the Greeks ascended to fully four hundred years beyond that date. The histories and traditions of the Hebrews, and other antient nations, extend much farther back. To provide a more comprehensive mode of reckoning, Joseph Scaliger, in 1582, invented what he called (after Julius Cæsar) the Julian period, being a cycle of 7980 years, which is the product of the continued multiplication of 28, the number of the solar cycle, 19 that of the lunar, and 15 that of the indiction. The advantage of this construction of the period is, that the place of any of its years in any one of these cycles is at once found by a simple process of division. It is found that the first year of the Christian æra must, according to its position in these three cycles, have been the 4714th of the Julian period. We have therefore, in this period, a chronological measure which may be applied, if necessary, over all that space before the birth of Christ. But as some chronologers have carried the creation of the world, or the beginning of human history, back to a date still more remote than B.C. 4714, a Capuchin friar, named Jean Louis d'Amiens, in 1683, proposed another period, to which (after Louis XIV.) he gave the name of the Louisian, composed of 15960 years, which number he produced by the multiplication of the numbers of the solar and lunar cycles not by 15, the number of the indiction, but by 30, the number from which the epact is reckoned. In this period the vulgar æra commences with the year 7373. But the Louisian period has been very little used by chronologers.

If the date of the creation of the world, or rather of man's appearance on the earth, could be certainly established, that would form the natural and most convenient point from which to commence the reckoning of time and to date the events of human history. None of the antient chronologers attempted to fix this point; a common opinion then held was, that the world was eternal; some conceived that any attempt to discover the commencement of its existence would be an act of impiety. Even among the Jews and Christians, whose sacred writings begin their record of events from the creation, there has been the greatest diversity of opinion as to that epoch. Kennedy in his 'Scripture Chronology,' affirms that 300 different opinions might be collected as to the length of time that elapsed between the creation and the incarnation. John Alb. Fabricius, in his 'Bibliotheca Antiquaria,' has given a list of 140 of these determinations. Dr. Hales, in his 'New Analysis of Chronology,' has collected above 120. In the 'L'Art de Vérifier les Dates,' vol. i., p. xxvii., &c., is given a list of 108. Playfair has given one of 88. Desvignoles, in the preface to his 'Chronology of Sacred History,' asserts that he has collected above two hundred such calculations, of which the longest makes the distance between the two points to have been 6984, and the shortest only 3483 years.

The uncertainty and controversy upon this subject have been principally occasioned by the disagreement in the ages assigned to the Patriarchs, and in other numbers, between the Hebrew text of the Old Testament, and the texts of the Samaritan and Septuagint versions. From the creation to the deluge the computation of the Hebrew text makes 1656 years to have elapsed; the Samaritan version only 1307; and the Septuagint 2262. The common opinion of modern theologians, and also of chronologers, has been that the Hebrew text is correct; and it is upon this assumption that Archbishop Usher, whose reckoning has been most generally adopted, has fixed the distance between the creation and the birth of Christ at 4004 years. But those who hold a contrary opinion, although the least numerous, have, according to Bayle, been usually *des savans d'élite*, inquirers of a superior order. It is maintained by Father Pezron, in his work 'De l'Antiquité des Tems,' that the Hebrew text was designedly corrupted by the Jews in the first century, and the time that had elapsed from the creation made to appear shorter than it really was, in order to meet the argument derived from what is said to have been an old Jewish tradition, that the coming of the Messiah should take place when the world was six thousand years old. Rabbi Akiba is supposed by Pezron to have been the author of the falsifications. Pezron makes the world to have been 5872 years old at the birth of Christ. The supposition of the corruption of the Hebrew text, and the preference due to the Greek translation of the LXX., has been recently adopted and supported by Dr. Hales, who will scarcely however be reckoned one of the *savans d'élite.*

Among modern systems of chronology, one of the most remarkable and peculiar is that proposed by Sir Isaac Newton, in his posthumous work, 'the Chronology of Antient Kingdoms amended,' 4to., London, 1728. Newton, assuming the nearly entire valuelessness of the determinations of the dates of antient events by the Greek chronologers and their followers, proceeds to form a new system on considerations wholly independent of their authority. In the first place he has endeavoured to show that the antient historians, when 'a little after the death of Alexander the Great, they began to set down the generations, reigns, and successions, in numbers of years, by putting reigns and successions equipollent to generations, and three generations to 100 or 120 years (as appears by their chronology), have made the antiquities of Greece three or four hundred years older than the truth.' He contends that the reigns of kings on an average do not exceed eighteen or twenty years. Secondly, he has endeavoured to ascertain the date of the famous Argonautic expedition by an ingenious calculation founded upon the known precession of the equinoxes at the rate of a degree in seventy-two years*, and the assumption of the equinoctial and solstitial colures having at the time of the expedition cut the ecliptic in the cardinal points. From these data he determines the expedition to have taken place about the year B.C. 928, which gives an antiquity less by about three centuries than that commonly assigned to the event. But the grounds on which Newton has assumed the position of the colures at the time of the expedition are now generally acknowledged to be quite insufficient. Although the full exposition of this system was not published till after the death of the author, its general principles got abroad during his lifetime, and were attacked from various quarters. The two chief early assailants of the Newtonian chronology were the learned French Jesuit Souciet, and Nicolas Freret, known for his many valuable contributions to the memoirs of the Academy of Inscriptions. In latter times the system has been examined by Playfair (pp. 35—37), and by Hales (vol. i., pp. 26—29). See also Sir David Brewster's late *Life of Newton*, and a valuable note by M. Daunon to the article on Newton by Biot in the 'Biographie Universelle,' vol. xxxi., pp. 180—186. Clinton denies that the general uncertainty of the early Greek chronology is so great as is supposed by the scheme of Newton.

Although Newton's deduction of the date of the Argonautic expedition from the precession of the equinoxes cannot be depended on, owing to the want of any authority for the position of the colures at the time of the expedition, the science of astronomy has in another way rendered valuable assistance to that of chronology. This it has done by the means which it affords of ascertaining the exact date of many eclipses of the sun and moon which are recorded by antient writers, and are sometimes connected by them with historical events that happened at or near the same time. In the first volume of the great French work, 'L'Art de Vérifier les Dates' (pp. 146-265), are given lists first of all the eclipses of the sun and moon which could have been seen to the north of the equator for ten centuries preceding the birth of Christ; and secondly, of all those recorded before that epoch by antient writers. In a subsequent volume of the same work there is inserted a list of the visible eclipses that have happened since the commencement of the vulgar æra. Lists of eclipses, solar and lunar, are also given in Playfair's 'Chronology,' pp. 175-219. As an example of the astronomical examination of a recorded antient eclipse, see the article ALYATTES.

One of the earliest of the Christian systematic chronologers is Sextus Julius Africanus, who appears to have flourished in the first half of the third century. Of his chronological work, entitled 'Pentabiblos,' however, beginning with the creation, which he dated B.C. 5499, and ending with A.D. 221, only some fragments remain. [AFRICANUS, vol. i. p. 190.] The most important of the works of the early Christian chronologers which we now possess is the Chronicon of Eusebius Pamphili, bishop of Cæsarea, in the fourth century, of which an edition was published with notes by Joseph Scaliger in 1658, in one volume folio, containing the Latin translation by Saint Jerome, and Scaliger's attempted restoration of the lost Greek text. The Armenian version of the Chronicon of Eusebius, which is more complete than the previous editions, was published at Venice in 1818, with a literal Latin translation, and another Latin translation of it, in the same year, at Milan. There is a famous Spanish commentary upon the Chronicle of Eusebius, by Alfonso Tostato, printed at Salamanca, in five volumes folio, in 1506. The work which is to be considered as having laid the foundation of the modern science of chronology is that of Joseph Scaliger, 'De Emendatione Temporum,' first published in folio at Paris in 1583, and afterwards, much augmented and amended, at Leyden in 1598, and at Geneva in 1629. Another important work of that age is that of Dionysius Petavius, or Petau, 'De Doctrinâ Temporum,' two vols. folio, Paris, 1627, with the Continuation in one vol. folio, Paris, 1630, entitled 'Uranologion, sive Systema variorum auctorum qui de Sphæra ac Sideribus, &c. commentati sunt.' An abridgment of this work, under the title of 'Rationarium Temporum,' was published at Paris in 8vo. in 1630, and has been several times reprinted. Of other early continental works on chronology the following are some of the most valuable, or the most celebrated:—Sethi Calvisii 'Opus Chronologicum,' Leips. 1603, often reprinted; J. Bapt. Riccioli, 'Chronologia Reformata,' 2 vols. fol., Bonon. 1669; 'L'Antiquité des Tems rétablie et défendue,' par le Père Paul Pezron, Paris, 4to., 1687, and the Defence of that work by the author, Paris, 4to., 1691; Hier. Wecchietti Florentini, 'Opus de Anno Primitivo ab exordio Mundi ad Annum Julianum accommodato,' fol., August. Vindel., 1621, a work for which the learned and unfortunate author was shut up during the remainder of his life in the prisons of the Inquisition, his crime being his maintenance of the opinion that Christ did not celebrate the passover the last year of his life, and, in instituting the Eucharist, did not make use of unleavened bread; Philippi Labbe et Philippi Brietii 'Chronologia Historica,' 5 vols. fol., Paris, 1670; 'Chronologie de l'Histoire Sainte,' par Alphonse Desvignoles, 2 vols. 4to., Berlin, 1738. The work of the Benedictine monks, Maur d'Antine, Durand, and Clemencé, first published in 1 vol. 4to. at Paris, in 1750, has, in the latest edition, extending to 38 volumes 8vo., published at Paris, 1818-1831, become the most extensive and important work on general chronology that exists. The principal works by English authors upon this science are the 'Chronicus Canon Ægyptiacus, Ebraicus, et Græcus,' of Sir John Marsham, fol., London, 1672, and also Leipzig, 1676, and Francfort, 1696; Archbishop Usher's 'Annales Utriusque Testamenti,' fol., Lond., 1650, and several times reprinted; Sir Isaac Newton's work, already noticed; Jackson's 'Chronological Antiquities,' 3 vols. 4to., 1752; Blair's 'Chronology and History of the World, from the Creation,' fol. 1754, and again, 1768, with additions; Kennedy's 'Complete System of Astronomical Chronology, unfolding the Scriptures,' 4to., 1762; Playfair's 'System of Chronology,' fol., Edin., 1784; and the Rev. Dr. William Hales's 'New Analysis of Chronology, in which an attempt is made to explain the History and Antiquities of the Primitive Nations of the World, and the Prophecies relating to them;' 3 vols. 4to., 1800-1812. There is also a useful introduction to chronology by Bishop Beveridge, entitled 'Institutionum Chronologicarum Libri Duo, una cum totidem Arithmetices Chronologicæ Libellis,' 8vo., Lond., 1669, and several times reprinted. Particular portions of antient chronology have been ably illustrated by Corsini in his 'Fasti Attici, in quibus Archontum Atheniensium series, Philosophorum, aliorumque illustrium virorum ætas, atque præcipua Atticæ Historiæ capita, describuntur,' 4 vols. 4to., Flor., 1744—61; by Wesseling, in his edition of Diodorus Siculus, 2 vols. fol., Amster., 1745; by Dodwell, in his 'Annales Thucydidei et Xenophontei,' 4to., Oxford, 1702; and by Larcher, in his 'Essai de Chronologie sur Hérodote,' already mentioned. But in so far as the Greek chronology is concerned, the most comprehensive, elaborate, and valuable work that has appeared is that of Mr. H. F. Clinton, entitled 'Fasti Hellenici: the Civil and Literary Chronology of Greece, from the earliest accounts to the death of Augustus,' now completed in three volumes 4to., of which the first, comprising the Chronology from the earliest accounts to the time of Pisistratus, was published at Oxford in 1834; the second, comprising the period from Pisistratus to Ptolemy Philadelphus, in 1824; and the third, completing the review to the end of the reign of Augustus, in 1830.

---

* Properly a degree in about 71½ years.

The volumes of chronological tables that have appeared are too many to be enumerated. Several of the systematic works on chronology that have been mentioned contain collections of such tables. The only other work which we shall mention is a most useful and, as far as we have examined it, very accurate publication, in one small volume, by Sir Harris Nicolas, entitled 'The Chronology of History' (1833), forming the 44th volume of Dr. Lardner's 'Cabinet Cyclopædia.'

[See the articles ÆRA, EPACT, EPOCH, CYCLE, DAY, MONTH, YEAR, INDICTION, &c.]

CHRONOMETER, a name applied to those timekeepers which are used for determining the longitude at sea, or for any other purpose where an accurate measure of time is required, combined with great portability in the instrument. The general appearance of what is termed a pocket chronometer is that of a common watch, and it is generally made to go the same time, with once winding up, namely 30 hours. Those used for nautical purposes are larger, having dial-plates from three to four inches in diameter, and are usually made to go from two to eight days between each time of winding up; they have, in addition to the hour, minute, and seconds', circles, one on which a hand denotes the time in days that the piece has been going since the last winding up. Each chronometer is well secured in a brass box, mounted on gimbals in order that the machine may preserve one uniform position, and enclosed in a mahogany case.

A chronometer, like a common watch, has for its moving power a main-spring, the variable force of which is equalized or rendered uniform by the introduction of the fusee, a very beautiful contrivance, which, when properly made, completely answers the intended purpose. This fusee is nothing more than a variable lever, upon which the main-spring acts through the medium of the chain. A common observer would say of the fusee that it was a sort of cone upon which the chain was wound from the barrel by the operation of winding up the machine; but it is in reality a mathematical curve which has this peculiar property, that as the chain winds upon it, the distance from the centre of motion of the fusee to the semidiameter of the chain which is in contact with it continually varies; and also that it varies in this proportion, viz.: that the distance of the centre of motion of the fusee to the semidiameter of the chain at that point where it leaves the fusee for the barrel, multiplied by the force of the main-spring acting on the chain at that time, shall be what mathematicians term a *constant quantity*: that is, shall be the same whatever point of the fusee may be taken. Thus: suppose the chain, which receives its power to turn the fusee from the main-spring, pulls with a force of 9 oz., and that the distance from the centre of motion of the fusee to the semidiameter of the chain at that part where it leaves the fusee is 42 hundredths of an inch, or, expressed decimally, ·42; then $9 \times {\cdot}42 = 3{\cdot}78$. Now let the spring be wound up to different points at which its force will be respectively 12 oz., 18 oz., 20 oz., 30 oz., and 40 oz., the corresponding distances at which the chain must pull from the centre of the fusee will be respectively ·315, ·21, ·189, ·126, and ·0945 of an inch, for ${\cdot}315 \times 12 = 3{\cdot}78$. ${\cdot}21 \times 18 = 3{\cdot}78$, ${\cdot}189 \times 20 = 3{\cdot}78$, ${\cdot}126 \times 30 = 3{\cdot}78$; and ${\cdot}0945 \times 40 = 3{\cdot}78$. Thus at any given distance from the centre of motion of the fusee, its power to turn any machinery is uniformly the same; and as the great or main wheel, which communicates motion to all the rest, in the watch or chronometer, is attached to the fusee, their centres of motion coinciding with each other, it follows that the power at the teeth of the main wheel is perfectly uniform: this power is transmitted through the medium of a train of wheels and pinions till it comes to the escapement, which is of the detached kind. It is necessary here to observe, that by a detached escapement is meant one in which the impulse which causes the balance to vibrate is given suddenly, and the balance performs two vibrations before it receives another impulse; so that the balance vibrates nearly independently of the maintaining power, the impulses being given so rapidly that the force applied acts on the balance during an extremely small part of one out of every two vibrations.

A chronometer differs from a common watch, in the escapement which has been just described, and in having a compensation for heat and cold. We shall here describe only the peculiar mode of effecting this compensation, as applied in a modern chronometer. It consists in having what is technically termed an expansion balance; this balance, with its appendage, the balance-spring, forms a very important part of a modern timekeeper; and there are few mechanics who can begin and finish this part alone; when they can do this, and adjust the machine to time, it is a proof they possess talents of no ordinary kind, for it requires a keenness of sight, a delicacy of touch, a degree of patient perseverance combined with tact and judgment in detecting errors, almost beyond belief; and last, but not least, a temper not to be ruffled by oft-repeated disappointments.

The figures 1 and 2 represent each a balance; some being made with weights, W W, as in figure 1; others with screws, as in figure 2. The nature and purposes of this balance will be best understood by explaining the mode of manufacturing one of them.

A circular piece of steel, of the thickness of the intended balance, is turned perfectly true, with a small hole in its centre, in which its arbor or axis is afterwards secured, and upon which it is ultimately poised; the piece of steel is then put into a melting pot (sometimes secured to it by a pin through the hole in the centre) with a sufficient quan-

Fig. 1

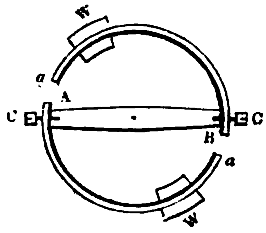


Fig. 2

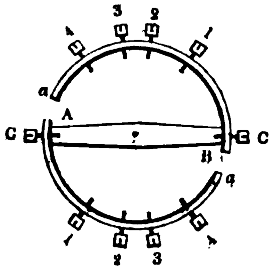


tity of fine brass to cover the steel when the brass is melted. After having cooled gradually, the superfluous brass is filed away from each side of the flat piece of steel, so that the steel is completely cleared of brass everywhere, except on the edge: by this means the artist is enabled to judge of the comparative soundness of the juncture of the ring of brass to the steel which it now encircles, and if any unsoundness appears it is thrown aside; if perfectly sound, the brass is now reduced by a file upon its outer edge, so as to present a ring of tolerably equal thickness all round, and is left about double the thickness wanted; it is then very carefully condensed either by the hammer or a burnisher as equally as possible, after which the steel is turned out of the centre and the brass from the outer edge, leaving a compound ring perfectly true of the proper thickness for the balance, and having the brass part about twice the thickness of the steel. Within the steel rim a bottom is left, out of which the bar A B is cut; the cutting through of the compound rim is the last thing done to the balance previous to its required adjustment, and this is done by dividing it on opposite sides, as shown in the figures by the letters *a, a, a, a;* so that each arm may present nearly a semicircle, secured at one end to the bar A B, and being free to move through the rest of its length, as will be shown when we explain the principle of action. In those balances where weights are used, a piece of brass is turned somewhat thicker than the balance, a groove is also turned in it whose depth is equal to the thickness of the balance, and breadth is just sufficient to allow the brass to move round on the balance with a slight pressure when formed into the weights W W, which are secured in their places by a small screw through their outer edge pressing against the rim of the balance. Two screws, C C, are called mean-time screws, and are merely used for altering the rate of the time-keeper, having nothing to do with the compensation.

The principle upon which this balance acts is as follows:—an increase of temperature diminishes the elastic force of the balance-spring, which would cause the machine to lose; but the same degree of heat expands the outer rim of the balance, which is brass, more than it does the inner one, which is steel; and not being able to separate, a curvature of the whole arm takes place, which carries the weight W towards the centre, and thereby the inertia of the balance is so much lessened as to allow the balance-spring to exert the same influence over the balance as it had previous to the change of temperature. Again, a diminution of temperature increases the elasticity of the spring, which would cause the machine to gain; but the brass contracting more than the steel, produces a curvature of the arm outwards, which increases the inertia of the balance, and allows the spring no more influence over it than it had previous to the change of temperature. The proper situations of the weights W W are found by experiments on the rate of the machine. It is evident that the nearer the weights are to the moveable ends *a a* of the arms, the greater will be the space through which they move by any change of temperature, and consequently the greater the variation in the inertia of the balance; whence, if an increase of temperature causes the machine to lose, or a decrease of temperature causes it to gain, it shows the compensation not to be sufficiently active; or, in other words, the inertia of the balance is not altered sufficiently to compensate for the effect produced by the increased or diminished elasticity of the spring, and consequently the weights must be set nearer to the moveable ends *a a* of the arms. If an increase of temperature causes the machine to gain, or a decrease to lose, then the weights must be moved farther fromthe moveable ends *a a* of the arms. In adjusting those balances made with screws, it will readily be perceived that the moving in or out the screws 4 4 will produce a greater effect than 3 3, and these again a greater than 2 2, and so on; and also that in the adjustment two opposite screws must always be moved in or out the same quantity: it will be further seen, that the mean-time screws C C can produce no effect on the compensation, as no motion is given to them by the curvature of the arms. It has been found by experiment, that in every balance-spring of sufficient length, there is a part of it which will be isochronal, or nearly so, and this length being found, it is not desirable to alter it in bringing the machine to time; for, if it be shortened, the long vibrations will be quicker than the short ones, and if lengthened, the short vibrations will be quicker than the long ones; and to avoid this source of error, the two screws C C have been introduced, the drawing out of which from the centre causes the machine to lose, and the screwing them in to gain. Considerable advantages have been anticipated by some persons from the application of a balance-spring of glass, the invention of Mr. Dent, of the firm of Arnold and Dent, of the Strand, London, but we believe it is not yet in a state to induce the inventor to bring it before the public, though we are informed that there is every prospect of ultimate success.

The following have been some of the most eminent chronometer-makers in this country, which has certainly produced them superior to those of any other nation in the world:—Harrison, Mudge, Earnshaw, Sen., Arnold, Sen., Brockbank, Barraud, and Messrs. Arnold and Dent.

CHRONOMETER, in music, an instrument by which the movement, or time (*i.e.* the quickness or slowness) of a composition is determined.

The musical chronometer is by no means a modern contrivance; so far back as the year 1636 Mersenne described and recommended it, in his *Harmonie Universelle;* and Malcolm, a very sensible writer, urged its use more than a century ago. Yet, owing to the prejudices of musicians, it has till lately not been employed, though its utility has never been disputed by any person of discernment, Diderot only excepted, who most likely was led astray by some bigot incapable of taking a clear view of the subject. We must however do Dr. Crotch, an enlightened professor, the justice to say, that it is now upwards of thirty years since he advocated the use of a pendulum. The opponents of a *time-measurer* either blindly or wilfully presume that it is meant rigorously to govern the *whole* of a composition, and that thus the beautiful effects of acceleration and retardation are to be sacrificed; but those who have advised the employment of a pendulum never contemplated its being used for any other purpose than to indicate the time to be adopted at the *commencement* of a movement. From the want or neglect of some contrivance by which the intention of composers might have been transmitted, we are now obliged to guess the true movements of the most classical works; and it is notorious that many compositions of the highest excellence, and among them several of recent date, are frequently performed in times which could not have been intended, because by good critics admitted to be exceedingly prejudicial to their effect. The invention, by the ingenious M. Maelzel, of a most accurate and convenient machine which he calls a Metronome, is beginning to convince musicians of the utility of a pendulum; and we are persuaded that not many years will elapse before it will be universally adopted, both by composers and performers. [METRONOME.]

CHRUDIM, a circle in the eastern part of Bohemia, is bounded on the north by the circle of Königgrätz, and on the east and south by Moravia. Its area is 1218 square miles, and it contained, in 1817, a population of 248,758, and in 1834 of 300,100 inhabitants, who are chiefly native Bohemians. The circle is traversed in the western part by the Elbe, and along its whole length, from east to west, by several rivers, which form a junction, and receiving the name of Chrudimka, fall into the Elbe near Königgrätz. The eastern division of the circle, where it joins the Glatz chain, is mountainous and thickly wooded; the western part is level, and watered by numerous streams; it also contains about 400 ponds. The soil is fertile and produces excellent corn, hay, clover, &c. and flax; it abounds in pasture and woodland, game, fish, &c., and contains also iron, some mineral springs, and precious stones. Much attention is paid to the rearing of horses; but the chief employment of the inhabitants is manufacture of flax and wool; there are likewise extensive potteries, glass-houses, and paper-mills. The circle contains 9 towns, 25 market-towns, and 761 villages.

The chief towns of the circle, besides Chrudim, the capital, are Leitomeschl on the Lauzna, containing 5806 inhabitants, a college, gymnasium, and manufactories of linen, spirits, &c. Pardubits, a royal town at the junction of the Chrudimka with the Elbe, with 3665 inhabitants, a high school and establishments for rearing horses for the army; Landskron, with 4246 inhabitants; manufactories of chintz, cottons, and linens; dyeing, bleaching, &c. Hohenmauth on the Meyto, 4568 inhabitants, factories of cloth; Policzka, 2823 inhabitants, contains a high school, and carries on trade in cloth, flax, and linen; and Wildenschwerdt, 2878 inhabitants, has manufactories of cloth and linens.

CHRUDIM, the capital of the circle, a royal appanage, lies on the right bank of the Chrudimka. It is well built, surrounded with walls, and contains a magnificent collegiate church, a capuchin convent, and a high school (Hauptschule). It is the seat of the local government, and, in 1834, had a population of 5625 inhabitants. The city has its own civil court. The time of the foundation of Chrudim is not known; but it is certain that it was reckoned one of the Bohemian towns in the year 1055. N. lat. 49° 46′., E. long. 15° 50′.

CHRY′SALIS. [PUPA.]

CHRYSA′NTHEMUM, a name applied to a genus of composite flowers, most of which are wild in different parts of Europe, and of little general interest; it is however popularly known from its also comprehending the Chrysanthemum Sinense, a Chinese half-shrubby plant, whose numerous varieties constitute one of the chief ornaments of gardens in the months of October, November, and December. The native state of this species is not certainly known, all the many varieties now in gardens having been bought in the markets of Macao, from the Chinese traders. In the cultivated state the plant has bluish-green broad leaves with sharp serratures and deep lacerations; and the flower-heads consist exclusively of ligulate florets of almost every colour, except blue. Pure white, bright yellow, deep and pale red, rich purple, and a dark morone brown, occur in different varieties of this favourite flower, and together contribute to the beauty for which the species is so much admired. It is probable that the numerous varieties cultivated by the Chinese and now introduced to Europe have been the result of ages of careful improvement, and that their properties have been derived partly from mere sporting and partly from intermixture with allied species unknown in Europe; for among those now cultivated are varieties remarkably different in constitution, some being capable of bringing their beautiful flowers to perfection in the open air, and others hardly unfolding them even beneath the atmosphere of a green-house or stove. They all strike root with great facility by cuttings, which should be taken from the parent plant at midsummer, and planted in a cool frame under a bell-glass. After rooting they may be successively transferred from one sized pot to another, until they have formed two or three stout stems ready for flowering, when they must be finally left at rest. If the soil in which they grow is rich, and the air cool and moderately moist, with a free exposure to light, cuttings struck at midsummer will flower beautifully in the succeeding autumn. The size and perfection of their flowers is increased by about half of the flowerheads that naturally appear being destroyed. As the varieties of this plant are very different in their degree of hardiness and beauty, the following classification of them is transferred from the pages of the Horticultural Transactions:—

1. *Flowers large or showy; requiring protection.*

Superb white.
Paper white.
Sulphur yellow.
Golden yellow.
Curled lilac.
Curled blush.
Semi-double quilled pink.
Starry purple.
Early crimson.
Pale flamed yellow.
Tasselled white.
Semi-double quilled white.
Quilled flamed yellow.
Tasselled lilac.
Large lilac.
Blush ranunculus flowered.
Brown purple.
Two-coloured red.
Pale buff.

2. *Flowers large or showy; quite hardy.*

Quilled white.
Superb clustered yellow.
Changeable white.
Tasselled yellow.
Golden lotus-flowered.
Parks's small yellow.
Rose or pink.
Purple.
Buff, or orange.
Small yellow.
Early blush.
Pale pink.
Changeable pale buff.
Spanish brown.

3. *Flowers large or showy; but produced sparingly.*

Semi-double quilled orange.
Expanded light purple.
Large quilled orange.
Quilled light purple.
Two-coloured incurved.

4. *Flowers small, or late; not worth cultivation.*

Double Indian white.
Yellow warratah.
Windsor small yellow.
Quilled salmon colour.
Semi-double quilled pale orange.
Late pale purple.
Double Indian yellow
Late quilled yellow.
Quilled yellow.
Quilled pink.

The varieties of the 2nd class may be cultivated without any protection by having their stems pegged down upon the surface of the earth so as not to be allowed to rise more than a few inches above it when in flower. So treated they form a charming ornament of a flower-garden; but the other kinds do not like this treatment.

Lately seeds of these plants have been obtained at Oxford and in Jersey, and many new varieties have been raised, among which are some that rival the handsomest of the Chinese sorts; but not much is at present known of their merits. None of them can however be compared to the 'two-coloured incurved,' which is the finest and rarest of the whole.

CHRY′SAOR. One of the numerous genera into which De Montfort divided the belemnites.

CHRYSA′ORA, (Zoology). [MEDUSA.] Also applied to a genus of polypifers of the family *Milleporidæ*. [MILLEPORIDÆ.]

CHRYSI′DIDÆ, a family of Hymenopterous insects of the section *Pupivora*. Distinguishing characters:—No nervures to the under wings; terminal segments of the abdomen forming a jointed retractile ovipositor; abdomen of the females with only three or four distinct segments, concave or flat beneath; antennæ thirteen-jointed in both sexes, and geniculated; mandibles slender, curved, and pointed; maxillary palpi filiform, generally longer than the labial palpi, and five-jointed; the labial palpi are generally three-jointed.

The Chrysididæ are most of them, if not all, of parasitic habits, that is to say, they seek the nests of other insects where they deposit their eggs to the destruction of the rightful owners; each species of this family apparently confining its attacks to the nest of some other Hymenopterous insect, and generally selecting those of the same species. They are all of brilliant colouring, very active, and fly about in the sunshine; some are seen upon flowers, and most of them upon old walls, palings, and sand-banks. Some of these species are called *ruby-tail flies.*

Chrysis ignita will afford a good illustration of this family. This insect is rather less than half an inch in length, has the head, thorax and legs of a rich blue or green colour, and the abdomen of a burnished golden-copper hue; this part is truncated at the apex, and furnished with four little spines.

It will be perceived that the above is a description of a little four-winged fly, which so often attracts our notice from its brilliant colouring, and is so common on our garden walls when the sun is on them. This little insect is in constant motion, for if it ceases running or flying for a moment its little horns still keep up their vibratory motion. If we watch one of these insects for a short time, we perceive that it thrusts its head into every little hole in the brick-work; it is then searching after the nest of a wasp-like insect which builds in these situations.

The principal genera comprised in the family *Chrysididæ* are Panorpes, Chrysis, Stilbum, Hedicrum, Elampus, and Cleptes. An account of the habits of one of the species of Panorpes will be found under the head *Bembex*, where the habits of *Bembex rostrata* are given, that being the species whose nests are subject to the attacks of the Panorpes which we are about to describe.

The genus *Panorpes* is distinguished from the other genera above mentioned principally by the elongated maxillæ and labium, which appear like a proboscis, and the palpi being very small and two-jointed. *Panorpes carnea* is about half an inch in length, and considerably broader than the *Chrysis ignita* (above described); the head, thorax, and base of the abdomen are of a blue-green colour; the remainder of the abdomen and the legs (with the exception of the thighs, which are blue) are of a reddish-yellow colour. It is found in various parts of Europe, but has not yet been discovered in England.

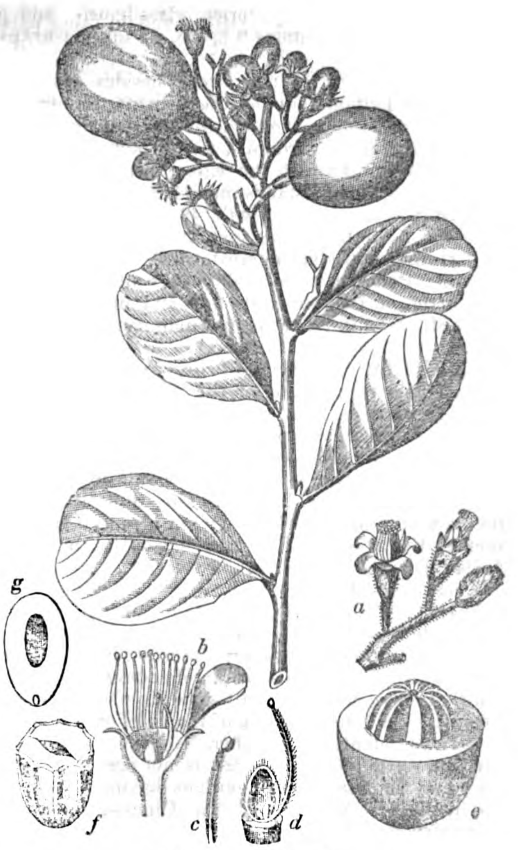
The technical characters of the genus *Chrysis* are:—Maxillary palpi five-jointed, and longer than the labial; labial palpi three-jointed; thorax not narrowed in front; labium rounded. About six or seven species of this genus are natives of England. *Chrysis bidentata* is rather less than *C. ignita*, and differs from that species in having the thorax as well as the abdomen of a rich copper-like hue: the latter however has the apex blue. *Chrysis cyanea* is entirely of a blue colour.

CHRYSIPPUS, son of Apollonius, was born at Soli in Cilicia, B.C. 280. He appears to have been driven to study by having, in some way, lost or squandered his patrimony. When he determined on devoting himself to philosophy he went to Athens, and attended the instructions of Cleanthes, whom he afterwards succeeded. (Strabo, xiii., p. 610, Casaub.) Cicero (*De Nat. Deor.* ii. 6.; iii. 10), in common with other antient writers, describes Chrysippus as a skilful and acute dialectician, and (i. 15) accounts him the most ingenious expositor of the Stoic dreams. Habits of industry probably gave him an advantage over his rivals. Diogenes Laertius reports, upon the authority of Diocles, a statement of Chrysippus's nurse, that he seldom wrote less than 500 lines a day. It appears however that he indulged largely in quotations; and the actual amount of his original labour in composition cannot be gathered from the number of his productions. He is said by Diogenes to have written upwards of 705 volumes, many on the same subject. Cicero (*Tusc. Quæst.* i. 108) gives him the character of a careful collector of facts. After Zeno he was considered the main prop of the Porch (Cic. *Acad. Quæst.* iv. 75); and allusions are frequently made to the estimation in which he was held. (Juvenal, *Sat.* ii. 5; xiii. 184; Horace, *Epist.* i. 2. 4.)

Chrysippus sometimes exposed himself to the attacks of his enemies, Carneades in particular, by defending two opposite sides of the same question: but the arguments which were good in his were good also in others' hands. He frequently succeeded in entangling his hearers by the use of the logical form *sorites*, which is said to have been invented by him, and is called by Persius (*Sat.* vi. 80) 'Chrysippus's heap.' Sorites (σωρείτης) means 'a heap,' and is in logic a heap of propositions in the syllogistic form. (Cic. *Acad. Quæst.* iv. 16; Whately's *Logic*, p. 122.) Chrysippus did not spare his adversaries in his replies to their arguments; and some anecdotes which are told of him seem to show that he occasionally overstepped the bounds of moderation. Notwithstanding this, his style of argumentation was so much admired, that it was said, if the gods themselves were to use a system of logic, they would adopt that of Chrysippus.

Chrysippus appears to have held substantially all the main doctrines of the Stoic theology, though in some minute particulars he is said to have differed from Zeno and Cleanthes: the charges of impiety made against him are probably to be ascribed only to a peculiar method of advocating his opinions. He died, apparently from an apoplectic fit, at the age of seventy-three, B.C. 207. (Diogenes Laertius, book vii., *Life of Chrysippus*; Fabricii *Bibliotheca Græca*, vol. ii. pp. 392, 393.)

CHRYSOBALANA'CEÆ, a natural order of Polypetalous Exogens, allied to Rosaceæ and Fabaceæ (Leguminosæ), from which it differs in the style proceeding from the base of the ovary, and in its stamens being very irregular, often placed only on one side of the ovary. They are trees or shrubs, with alternate stipulate simple leaves, and flowers in loose racemes, corymbs, or panicles. Many species have no petals. They are exclusively natives of the tropics, where they often bear the name of plums. The grey or rough-skinned plums of Sierra Leone are produced by species of Parinarium, and the Callimato or cocoa plum of the West Indies belongs to Chrysobalanus Icaco. The fruit of the latter is described as long, black, clammy, sweet, and agreeable; the plant forms a shrub seven or eight feet high, with very long sharp-pointed leaves, dark green on the upper and pale on the under side: it loves a cool moist soil.



[Chrysobalanus Icaco.]

a, flowers in different stages of development; *b*, vertical section of the flower; *c*, stamen; *d*, vertical section of the pistil, showing the ovules in the base of the ovary; *e*, horizontal section of fruit, showing the inclosed nut; *f*, transverse section of nut; *g*, a cotyledon, with the plumule at its base.

CHRYSOBERYL, the *Cymophane* of Haüy, occurs massive and crystallized. Primary form, a right rhombic prism. Its colour is green, sometimes with a yellow or brown tinge, with occasionally a blue opalescence. Streak white. Lustre vitreous. It is translucent or transparent, Specific gravity about 3·8. Hardness 8·5. Fracture conchoidal. Before the blow-pipe it suffers no change alone; with borax it fuses into a transparent glass.

The massive variety occurs in rounded pieces.

It is found in Brazil, and in Connecticut, North America.

Analysis. Seybert first found that it contained glucina. The following are his and Dr. Thomson's analyses:—

Seybert.		Thomson.	
Alumina .	73·60	Alumina .	76·752
Glucina .	15·80	Glucina . .	17·791
Silica . .	4·06	Protoxide of iron	4·494
Protoxide of iron	3·38	Volatile matter	0·480
Oxide of titanium	1·00		
Moisture .	0·40		99·517
	98·18		

CHRYSOCHLO'RA, a genus of Dipterous insects of the family *Stratiomydes*. Technical characters:—Body elongated; antennæ with the basal joint short, the third long, conical, and compressed; stylet terminal, elongated; third posterior nervure of the wings not reaching the hinder margin.

Only three species of this genus are described; they are all of large size.

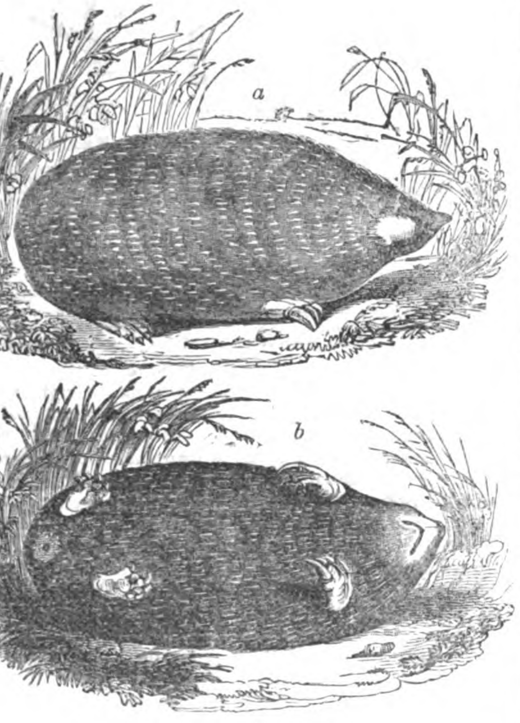
Chrysochlora amethystina is about three-quarters of an inch in length; the head and antennæ are black; there is a white spot at the base of each antenna; the thorax and abdomen are of a violet blue colour, the latter has a yellow spot on each side of the second, third, and fourth segments; the legs are black.

It inhabits the Isle of France and the East Indies. The remaining two species are from South America; their colouring is black and yellow.

CHRYSOCHLO'RIS, Lacepède's name for a genus of mammiferous animals allied to the moles (*Talpa*), but differing from them in their dentition and in other particulars. Dental formula:—Incisors $\frac{2}{4}$, canines 0, molars $\frac{9-9}{8-8}$ = 40. The true molars are long, distinct, and nearly all in the shape of triangular prisms.

The muzzle is short, wide, and reflected. There is no external ear, nor any appearance of the eye externally. The fore-feet have three claws only; the exterior claw is very large, arched, and pointed, forming a powerful instrument for penetrating and digging the earth; the other two diminish gradually. The hind feet are furnished with five claws of ordinary size. The fore-arm is supported by a third bone placed under the ulna, to strengthen it when the animal is employed in excavation. The body is thick and short. The hair, or rather fur, which is thick set, has a metallic lustre. Example. *Chrysochloris Capensis*, Desmarest; *Taupe dorée* of the French; *Talpa Asiatica* of Linnæus. Hair brown, presenting in certain lights very brilliant changeable green, bronze, and coppery tints. Cuvier says that it is the only quadruped whose covering reflects those metallic tints which render so many birds, fishes, and insects brilliant. There is no apparent tail.

Locality and Habits—The Cape of Good Hope, where it is said to live much in the same way as the mole, and to prey like it upon worms, &c.



[Chrysochloris Capensis]

a, the animal on its feet; *b*, the same turned up to show the claws, &c.

Lesson gives two species, the second being *Chrysochloris rufa* of Desmarest, *Talpa rubra* of Gmelin, described as having a short tail, four toes on the hind feet, the fur red inclining to bright ash, and as being somewhat larger than the European mole. *Locality*, Guyana. But Cuvier, in a note to the last edition of the 'Règne Animal' (where he gives only one species, *Chrysochloris Capensis*), says that the red mole of America (*Talpa rubra* of Gmelin), figured in Seba i., pl. xxxii., f. 1, is probably only a *chrysochloris* of the Cape, represented from a dried specimen, for in that state the fur would appear purple; but he adds that the *Tucan* of Hernandez ('Hist. Quad. Nov. Hisp.,' tract 1, p. 7, c. xxiv.), which is regarded as one of its synonyms, would rather appear, from its two long teeth in each jaw, to be a vegetable feeder, a *rat-taupe*, or some other subterranean rodent, such as the *Diplostoma*. Now pl. xxxii., fig. 1, in the first volume of Seba, is described by him to be *Talpa alba nostras*, a white European mole. Fig. 2 is indeed stated to be *Talpa rubra Americana*, the red American mole; but it is represented with a tail, and Seba describes it as having but four claws on the posterior feet. The dried state of the specimen might account for the colour, but not for the tail, and hardly for the four hind claws instead of five.

CHRYSOCOLLA. [COPPER.]

CHRY'SODON (Zoology), Oken's name for the *Pectinaires* of Lamarck, the *Amphictènes* of Savigny, and the *Cistenes* of Dr. Leach, forming a part of the genus *Amphitrite* of Cuvier, who well observes that these perpetual changes of names (and, he adds, in this case there is not even the pretext of a change of the limits of the group) will terminate in making the study of nomenclature more difficult than the study of facts. [TUBICOLÆ.]

CHRYSOGA'STER, a genus of Dipterous insects of the family *Syrphidæ*. Technical characters:—Body much depressed; no false nervures to the wings; third joint of the antennæ oval or orbicular.

About fourteen species of this genus have been discovered in England: they are all of moderate size, and their colouring is metallic.

Chrysogaster splendens is about one-third of an inch in length; the head is green; antennæ yellow; thorax golden-green; abdomen purple-black; greenish towards the sides; the legs are black; wings brownish.

This and all the other species recorded as British have been found in the neighbourhood of London.

CHRYSOLITE: *Peridot* of Haüy. Olivine is a variety of this mineral, and *Chusite* also, according to Dr. Thomson.

It occurs massive and crystallized. Primary form, a right rhombic prism. Colour green, sometimes brownish or yellowish; streak white. Lustre vitreous. Translucent, transparent, double refracting. Specific gravity 3·33 to 3·41. Hardness 6·5 to 7. Fracture conchoidal.

Massive varieties:—Amorphous; granular.

The chrysolite used in jewellery is brought from the Levant, and supposed to be found in Upper Egypt. The variety, on account of its colour called *olivine*, occurs in basalt in Bohemia, Hungary, and on the banks of the Rhine. The following are the analyses of

	Klaproth.	Vauquelin.
Silica . .	39·	38·
Magnesia . .	43·5	50·5
Protoxide of iron	19·	9·5
	101·5	98·0

Some varieties contain small portions of alumina and of the oxides of nickel and manganese. It does not fuse or lose its transparency before the blow-pipe. With borax it fuses into a coloured glass, and with soda into a brown scoria.

CHRYSO'LORAS, EMMANUEL, a learned Byzantine of the fourteenth century, was sent to Italy about 1397, by the Emperor Manuel Palæologus, to request the assistance of the Venetians and the pope, and the other Christian princes, against the Turks. Having fulfilled his mission, he settled at Venice, where he gave lessons in the Greek language. He afterwards taught the same at Florence, Pavia, and lastly at Rome, where he grew into favour with the papal court, and was sent to the council assembled at Constance, where he died in 1415. Poggio Bracciolini, Leonardo Bruni, and Filelfo, were the most distinguished pupils of Chrysoloras in Greek. Chrysoloras wrote a Greek grammar (entitled Ἐρωτήματα, *Questions*), which was one of the first published in Italy, and was afterwards printed at Ferrara in 1509. He also wrote several epistles in Latin, in one of which, addressed to the Prince John Palæologus, son of Manuel, he draws an eloquent comparison between Constantinople and Rome, which has been often quoted. Chrysoloras ranks among the restorers of classical learning in Italy.

John Chrysoloras, the nephew of Manuel, taught Greek in Italy: he returned to Constantinople, where he died about A.D. 1427. Demetrius Chrysoloras, probably a native of Thessalonica, wrote on philosophy and theology. Some letters of his to the Emperor Manuel Palæologus still exist in MS., and some other works of no importance.

CHRY'SOLUS. One of De Montfort's genera, ranged under the genus *Nonionina* of D'Orbigny, belonging to the order *Foraminifera* of that author.

CHRYSOME'LIDÆ, a family of Coleopterous insects, of the section *Cyclica*. Distinguishing characters:—Antennæ wide apart at the base and inserted before the eyes: body generally short and convex: tarsi short and rather broad, four-jointed, the penultimate joint bilobed; all th-joints, excepting the terminal joint, covered beneath with a velvet-like substance.

The Chrysomelidæ constitute a very numerous and beautiful family of the beetle tribe: they are generally of moderate size, and frequently very brilliant in colouring.

Between seventy and eighty species have been discovered in England, and the number of species contained in collections from various parts of the world may probably amount to four or five hundred.

This group may be divided into two sections, those in which the head is hidden beneath the thorax, and the body is frequently somewhat cylindrical; and those in which the head projects from the thorax so as to be distinctly seen when the insect is viewed from above, and where the body is generally rounded, or oval, and convex.

The first of these sections may again be readily subdivided according to the proportions of the antennæ. In some, the antennæ are short and more or less serrated: here belong the genera *Clythra*, *Lamprosoma*, and *Chlamys*. The species of this last genus are among the most remarkable of coleopterous insects. They are of small size, the largest being about half an inch in length, and the thorax and elytra are generally very uneven, and studded with numerous angular projections. This circumstance, together with the extremely brilliant colouring with which they are adorned, has caused them to be compared to pieces of minerals; indeed, one which is now before us, and which is of a beautiful red hue, we have known to be mistaken at first sight for a piece of copper ore. Most of the species of Chlamys inhabit Brazil, and none are found out of the western hemisphere. The generic characters are:—head vertical; thorax humped; the posterior margin produced in the region of the scutellum; body somewhat cube-formed; antennæ with the basal joint rather long, the second very small; the remaining joints dilated, and more or less serrated; labial palpi sometimes forked.

The remainder of the Chrysomelidæ of the first section have the antennæ long and slender. The genera are *Cryptocephalus*, *Choragus*, *Euryope*, and *Eumolpus*.

The second section, or those in which the head is apparent when the insect is viewed from above, comprises the genera *Colaspis*, *Podontia*, *Phyllocharis*, *Doryphora Cyrtonus*, *Paropsis*, *Apamœa*, *Timarcha*, *Chrysomela Phædon*, and *Prasocuris*.

The genus to which the name *Chrysomela* is now restricted, is principally distinguished by the following characters:—maxillary palpi with the terminal joint as large, or larger, than the preceding one, and of the form of a truncated cone, or nearly oval; the elytra are separate, i. e., not joined at the suture: no sternal projection.

Upwards of forty species of this genus have been discovered in England.

Chrysomela Banksii is one of the largest species of the genus: it is rather less than half an inch in length, and of a brown colour with a metallic lustre; the thorax has an indentation running parallel with and close to the lateral margins: the elytra are coarsely punctured. the legs and antennæ are ochre-coloured. It is found on nettles in the neighbourhood of London and elsewhere, but is rather local. *C. sanguinolenta* is about three-eighths of an inch in length, and of a dull blue-black colour; the elytra are rather rough. *C. graminis* is about the same size as the last, and of a bright green colour; this species is abundant in various parts of Cambridgeshire. *C. polita* is about a quarter of an inch in length, and very glossy; the head, thorax, and legs are green, and the elytra are of a reddish ochre colour. This species is very common in marshy situations. *C. cerealis* is about the same size as *C. sanguinolenta*. This is one of the most beautiful species of the genus. It is tolerably common in France and Germany, but till found on the summit of Snowdon (within the last three or four years), was scarcely known as a British insect. It is very glossy; the legs, antennæ, and under parts are blue: the elytra are adorned with longitudinal stripes of blue, green, and red; and the same colours are observed on the head and thorax. *C. Goettingensis* is of a purple colour, and the elytra are very finely punctured. This species is very common in chalk districts. [Cyclica.]

CHRYSO'PHILA, a genus of Dipterous insects. [Leptides.]

CHRYSO'PHORA, a genus of Coleopterous insects, of the section *Lamellicorne*, and family *Xylophili*. The principal generic characters consist in the immense size of the hind legs of the males. The sternum is produced into a somewhat pointed process between the second pair of legs; the posterior thigh of the male is very thick; the tibiæ are curved and produced at the apex internally into a long bent process: the hind legs of the female are thick, but comparatively short, and the hinder tibiæ are abruptly terminated: the outer claws of all the tarsi are larger (in both sexes) than the inner; they differ in the male, however, in being broader than in the female, and those of the anterior pair of legs are bifid; their outer claws are very long, and the insect has the power of bending them under so as to fix their points beneath a projection of the fourth joint of the tarsus:* they are probably used for clinging to the slender branches or leaves of trees.

But one species of this genus is known—*Chrysophora chrysochlora;* it is of a rich metallic green colour; the head, thorax, and scutellum are shagreened; the elytra are rugose throughout; the tibia of the hind leg is of a brassy or copper-like colour; all the tarsi are blue-black. The length of the hind leg of the male exceeds that of the body, which is about one inch and a half; the female is rather less. This beautiful insect inhabits Columbia.

CHRY'SOPHRYS, a genus of fishes of the family *Sparidæ*, and order *Acanthopterygii*. The species of this genus are distinguished from their allies by their having at least four rows of teeth above and three below; those in front are somewhat conical, and the remainder are molars of a rounder or oval form; the body is deep and compressed; the operculum is covered with scales; branchiostegous rays, six.

One of the species of this genus, the *Gilt-head* (Chrysophrys aurata), has been met with off our own coast, but it is here extremely rare. One of its chief localities appears to be the Mediterranean. It is about twelve inches in length; the body is somewhat oval, tapering towards the tail; and the greatest depth (which is about one-third of the whole length) is a little behind the gill opening, above which part the dorsal fin commences, and continues (in a specimen twelve inches long) to within about an inch and a half of the root of the tail. The pectoral fins are long and pointed; the tail is slightly forked. The colour is grey above and silvery beneath; numerous longitudinal gold-coloured bands adorn the sides of the body, and there is a semilunar band of the same colour between the eyes.

CHRYSOPHYL'LUM CAINI'TO, a West Indian fruit, commonly called the star apple, and belonging to the natural order Sapotaceæ. Like the rest of its kindred, it abounds in a sweet harmless milky juice, that flows most copiously when the tree is beginning to mature its fruit, which grows on a moderately sized spreading tree, with very slender flexile branches. The leaves are dark green on their upper surface, and are covered beneath with a remarkably satiny ferruginous pubescence. The flowers grow in small purplish bunches, and are succeeded by a round, fleshy, smooth fruit, resembling a large apple. In the inside it is divided into ten cells, each containing a black shining rhomboidal seed, and surrounded by a white, or sometimes purplish, gelatinous pulp, traversed with milky veins, and of a very sweet agreeable flavour. In an unripe state, the taste is said to be astringent and unpleasant. When cut across, the seeds, which are regularly disposed round the axis of the fruit, present a stellate figure, from whence the name of star apple is derived. There is a smaller species, which produces the fruit called the damson plum. The tree is common in the hot-houses about London, and is well represented in a fruit-bearing state in Sloane's 'Jamaica,' plate 229.

CHRYSOPRASE: Green Quartz. [Silicon.]

CHRY'SOPS, a genus of dipterous insects, of the family *Tabanidæ*. Technical characters:—Head hemispherical; antennæ elongated, second joint nearly as long as the first, both covered with fine hairs: third joint equal in length to the first and second taken together, and having five false joints or divisions; eyes of a golden green colour, with purple lines or spots.

Eight or nine species of this genus have been discovered, two of which only are found in this country.

Chrysops cæcutiens is rather larger than the common house-fly, the expanded wings measuring about two thirds of an inch. It is black; the male has a yellow spot on each side of the first segment of the abdomen; the female, in addition to these spots, has the second segment yellow, with two diverging black lines in the middle; the wings are whitish, the anterior border is broadly margined with black, and there is a broad black band near the middle: the wings of the male are nearly all black.

---

* This same structure may be observed in some other allied genera.

Most persons undoubtedly have been troubled more or less with the insect above described when walking in the country, especially in the neighbourhood of water. Three or four will sometimes settle on us at the same time, and if on the arm their presence is soon discovered by a sharp prick, caused by their thrusting the proboscis through the sleeve; the bite however is not venomous, and for the slight pain caused by it we are repaid by a sight of the little insect. Nothing can be more beautiful than its large eyes, which seem to reflect all the colours of the rainbow: they may be described as green with purple spots, but the green varies to golden and red hues in certain lights. When it first settles this fly is not easily caught, but it soon becomes so engaged in its occupation that it may almost be touched before it will move.

The other British species is the *Chrysops relictus*, which very closely resembles the one just described.

There is another genus of flies closely allied to Chrysops, and having the same habits; we mean the genus *Hæmatopota*, the principal characters of which are:—Antennæ with the basal joint generally long, thick, and downy in the male, conical and without down in the female; third joint with four divisions, of which the first is thick and longer than the others taken together; no ocelli; wings when at rest sloped like a roof.

Hæmatopota pluvialis is about the same size as the species of Chrysops just described; the eyes are green, having the under part purple, with yellow markings; the thorax is grey, varied with black; the body is black, with a central yellowish longitudinal line, and there is a row of spots of the same colour on each side of this; the wings are greyish, spotted with brown.

Four species of this genus are found in England; the one just characterized is very common.

CHRYSOSTOM. [DION.]

CHRYSOSTOM, ST. JOHN (*χρυσόστομος*, *i. e.* the golden-mouthed), the most renowned of the Greek fathers, was born of noble and very opulent parents, A.D. 354 (some writers say 344 and 347), at Antioch, the capital of Syria. In early life he lost his father Secundus, who was commander of the imperial army in that province; and his mother Anthusa, from the age of twenty, remained a widow, in order to devote herself wholly to her son's improvement and welfare. He was educated for the bar, and studied oratory at Antioch under Libanius, who declared him worthy to be his successor, were it not that the Christians had made him a proselyte. He was taught philosophy by Andragathius, and spent some time in the schools of Athens. After a very successful commencement of legal practice, he relinquished the profession of law for that of divinity. At this time the rage for monachism was extremely prevalent, and Chrysostom retired to a monastery in a mountain solitude near Antioch, where, in opposition to the pathetic entreaties of his mother, he adopted and adhered to the ascetic system with rigid austerity during four years. The manners and discipline of the anchorites with whom he associated resembled, as described by himself, those of the Essenes, in fasting, praying, reading, subsisting on vegetable food, maintaining silence and celibacy, and discarding all consideration of *meum* and *tuum*. (*Homil.* 72, *on Math.*, and 14, *on Timoth.*, tom. ii.) At the age of twenty-three he was baptized by Meletius, bishop of Antioch, after which he withdrew into a solitary cavern, where, without any companion, he spent about two years in committing to memory the whole of the Bible, and in severely mortifying his carnal affections. Having neither bed nor chair, he reposed suspended by a rope slung from the roof of his cave. The damp and unwholesome air of the place reduced him at last to so ill a state of health, that he was obliged to return to Antioch, where, being ordained a deacon by Meletius (A.D. 381), he commenced his career as a very eloquent popular preacher, and published several of his declamatory discourses and argumentative treatises. Five years afterwards he was ordained priest, and at the age of 43 was made vicar to Flavianus, successor to Meletius. His fame as a church orator was now so established, that, on the death of Nectarius, archbishop of Constantinople, he was enthusiastically chosen by the people and priesthood of the city to fill that important office. Chrysostom, on this and former occasions, appears to have reiterated with sincerity the *noli me episcopari:* however, by the mandate of the Emperor Arcadius, he was consecrated and enthroned A.D. 398 by Theophilus, patriarch of Alexandria, who afterwards proved to be one of the most envious and malignant of his enemies. Chrysostom bestowed upon the indigent the whole income of his large patrimonial inheritance; and with the revenues of his episcopal see he founded and endowed an hospital for the sick, which procured for him the appellation of John the Almoner. Several times a week he preached to crowded audiences, and his oratorical sermons were received by the people with such shouts and acclamations of applause, that his church became a sort of theatre, which attracted great numbers who had hitherto attended only the circus and other places of amusement. The resolute and fearless zeal of Chrysostom in the reformation of clerical abuses, and in the denunciation of licentiousness among the great, soon began to draw upon him the enmity of a confederate party, whose bitter retaliation finally effected his banishment and death. Much is said by various writers both in commendation and reprehension of his character and conduct. The church historian Socrates describes him as being 'sober, temperate, peevish, irascible, simple, sincere; rash, rude, and imprudent in rebuking the highest personages: a zealous reformer of abuses; extremely ready to reprove and excommunicate; shunning society, and apparently morose and haughty to strangers.' Such qualities embroiled him in continual quarrels with the secular clergy, courtiers, and statesmen, and especially with the wealthy female devotees of luxury and fashion. He appears to have delighted in incurring the implacable hatred of rich young widows, by often reminding them of their paint and ugliness. His zeal for the promotion of his own sect was equalled only by his intolerance towards all others. He caused many temples and statues in Phœnicia to be demolished, and especially persecuted the Arians, refusing them the use of a church in the city, and parading in the streets Trinitarian singers of hymns, with banners and crosses, until the opposition vocalists fell to fighting and bloodshed. The vigour and perseverance of his efforts to reform the loose ecclesiastical discipline permitted by his indolent predecessor, occasioned the formation of a faction which sought to be revenged by his assassination. In his visitation in Asia, two years after his consecration, he deposed at one time no less than thirteen bishops of Lydia and Phrygia; and in one of his homilies (tom. ix., p. 29) he charges the whole episcopal order with avarice and licentiousness, saying that the number of bishops who could be saved bore a very small proportion to those who would be damned. It appears to have been a common custom at that time among the clergy to have each one or more young females residing with them, ostensibly for the purpose of receiving pious instruction as pupils. When therefore Chrysostom enjoined the discontinuance of this custom, as in all cases very questionable, and in many most evidently criminal, he at once excited in the hearts of a great portion of his clergy a personal animosity, very similar to the wrath of Achilles when deprived of his mistress. It has already been remarked that the vanity and vices of the female sex were a favourite topic of Chrysostom's impassioned declamation. In these invectives he used no reserve in reproving even royalty itself. The personal resentment and indignation of the beautiful and haughty Empress Eudoxia was probably therefore the real cause, as Gibbon suggests, of all the disasters by which he was henceforth overwhelmed; for she patronized the confederation which the deposed bishops formed with his adversary Theophilus, who assembled at Chalcedon a numerous synod, by which there were preferred against Chrysostom above forty accusations, chiefly frivolous and vexatious, which, as he refused to acknowledge himself amenable to such a tribunal, and made no defence, were subscribed by forty-five of the bishops present, who in consequence resolved upon his immediate deposition. He was therefore suddenly arrested and conveyed to Nicæa in Bithynia, A.D. 403. This Theophilus is described by Socrates, Palladius, and several others, as a bishop addicted to perjury, calumny, violence, persecution, lying, cheating, robbing, &c. After Chrysostom's banishment Theophilus published a scandalous book concerning him—a sort of collection of abusive epithets—in which Chrysostom is called a filthy demon, and is charged with having delivered up his soul to Satan. It was translated into Latin by the friend of Theophilus, St. Jerome, who joined in the abuse Chrysostom was the idol of the great mass of the people. He was a pathetic advocate of the poor: his pulpit orations were calculated to excite their strongest emotions. When it was known therefore that their favourite preacher was banished, an alarming insurrection ensued, which rolled on with such fury to the palace gates, that even Eudoxia entreated the emperor to recall Chrysostom, for already the mob had begun to murder the Egyptian attendants of Theophilus in the streets. Only two days elapsed before Chrysostom was brought back to Constantinople. The Bosporus, on the occasion, was covered with innumerable vessels, and each of its shores was illuminated with thousands of torches. The archbishop however gained little wisdom from experience; for soon after, when a statue of the empress was set up near the great Christian church, and honoured with the celebration of festive games, he preached in very uncourteous terms against the ceremony, and compared Eudoxia to the dancing Herodias longing for the head of John in a charger. The result of this offensive conduct was the calling of another synod, which ratified the decision of the former, and again Chrysostom was arrested, and transported to Cucusus, a place in the mountains of Taurus. Another uproar was made by the mob, in which the great church and the adjoining senate-house were burnt to the ground. The death of Eudoxia shortly afterwards, and a tremendous storm of hailstones, were regarded by the people as the avenging visitation of heaven. A great number of the poorer class, who were always Chrysostom's most faithful adherents, refused to acknowledge his successor, and formed for some time a schism, under the name of Johannites.

Chrysostom bore his misfortunes with fortitude, and being still possessed of abundant wealth, he carried on very extensive operations for the conversion of the people about his place of banishment. His enemies soon determined to remove him to a more desolate tract on the Euxine, whither he was compelled to travel on foot, beneath a burning sun, which, in addition to many deprivations, produced a violent fever. On arriving at Comana, he was carried into an oratory of St. Basil, where, having put on a white surplice, he crossed himself and expired, September 14, 407, being about sixty years of age. Thirty-five years after his death and burial at Comana, his remains were brought with great pomp and veneration to Constantinople by Theodosius II. It is said they were afterwards removed to Rome. The Greek church celebrates his feast 13th November; the Roman, 27th January.

The works of St. Chrysostom are very numerous. They consist of commentaries, 700 homilies, orations, doctrinal treatises, and 242 epistles. The style is uniformly diffuse and overloaded with metaphors and similes. 'Chrysostom's peculiar talents were those of a declamatory preacher whose art lay in warming the passions, not in convincing the reason; and whose pompous style and rhetorical flourishes, instead of being adapted to a simple narration of facts, were apt rather to exaggerate facts into miracles.' (Dr. Middleton, *Mirac. Powers*, p. 72.)

Dr. A. Clarke, in his 'Succession of Sacred Literature,' vol. ii., has given a brief analysis of the principal treatises. He concludes by remarking, that in the works of Chrysostom there is hardly anything that favours the doctrines of the church of Rome; the opposite of which may be established by a very few examples. Chrysostom believed in the real presence of Christ in the eucharist, as a sacrifice (*Homil.* 24, *on Corinth.*); in the efficacy of prayers of and for the dead (*Homil.* 3, *on Philip.*): he states it to be one of the daily duties of a priest (*Six Books on Priesthood*) to pray for the dead. He often speaks of the miracles daily wrought by the relics of martyrs (ii., p. 555), by the sign of the cross (vii., p. 552; ii., p. 387; v., p. 271), and by consecrated oil (vii., p. 387). His belief in demoniacal possession and exorcism is shown in his 'Address to Stagirius.' His church was full of images and pictures (ii., p. 78).

The chief value of Chrysostom's works consists in the illustration which they furnish of the manners of the 4th and 5th centuries. They contain a great number of incidental but very minute descriptions that indicate the moral and social state of that period. The circus, theatres, spectacles, baths, houses, domestic economy, banquets, dresses, fashions, pictures, processions, chariots, horses, dancing, juggling, tight-rope dancing, funerals, in short every thing has a place in the picture of licentious luxury which it is the object of Chrysostom to denounce. Montfaucon has made a curious collection of these matters from his great edition of the works of Chrysostom, 13 vols folio (editio optima). (*Mémoires de l'Acad. des Inscrip.*, vol. xiii., p. 474, and vol. xx., p. 197; also Jortin, *Eccles. Hist.*, vol. iv., p. 169, et seq.) The 'Golden Book' of St. John Chrysostom concerning the education of children, 12mo., p. 1659, is translated from a MS. found in the cardinal's library at Paris, 1656. The precepts are very curious. The boy is to see no female, except his mother; to hear, see, smell, taste, touch, nothing that gives pleasure; to fast twice a week, to read the 'Story of Joseph' frequently, and to know nothing about hell till he is 15 years old. Chrysostom is described by his biographers as being short in stature, with a large bald head, a spacious and deeply-wrinkled forehead, short and scanty beard, hollow cheeks and sunken eyes, having a look of extreme mortification, but in his movements remarkably brisk, energetic, and smart. He was strongly attached to the writings of St. Paul. His surname Chrysostom was not applied until some time after his death. The biographers of Chrysostom are very numerous: Socrates, lib. vi.; Sozomen, lib. viii.; Theodoret, lib. v.; *Vie de St. Jean C.*, by Hermant, 8vo., 1665; Menard; Erasmus; Du Pin; Tillemont; Palladius; Photius; Ribadeneira; Gibbon, c. 32; Moreri's *Dict.* contains a further list; Priestley, *Hist. Church*, vol. ii.; Usher, *Historia Dogmatica*, p. 33; six sermons have been translated by Rev. W. Scott; and the *Treatise on Priesthood* by Bruce, &c. There is a recent life of Chrysostom by Neander.

CHTHAM'ALUS. [CIRRHIPEDA.]

CHUB. [LEUCISCUS.]

CHUBB, THOMAS, was born in 1679, at East Harnham, a small village near Salisbury. His father, who was a maltster, died without property, and left his mother in indigence to provide for four children. Thomas, the youngest, after receiving a little instruction in mere reading and writing, was apprenticed to a leather glove and breeches-maker in Salisbury. He was afterwards, as a journeyman, engaged in the business of a tallow-chandler in the same city. In both these employments he continued to be more or less concerned until the end of his life; and it certainly is a proof of remarkable mental energy that, in the midst of duties so humble, and merely manual, he contrived, by unassisted application, to acquire a general knowledge of literature and science, and to become a distinguished writer on subjects of religious and moral controversy. The discussion which arose on the publication, in 1710, of the Arian work of Whiston on Primitive Christianity, induced Chubb to write his 'Supremacy of God the Father asserted;' consisting of eight arguments from Scripture, proving the Son to be a subordinate and inferior being. It was published in 1715, under the immediate superintendence of Whiston, and by opposite parties was equally extolled and condemned. Chubb replied to his Trinitarian opponents in 'The Supremacy of the Father vindicated.' In 1730 he published a collection of his occasional tracts in a handsome 4to. volume; containing, besides the two works just mentioned, thirty-three others on faith, mysteries, reason, origin of evil, persecution, liberty, virtue, governmental authority in religion, &c. Pope, in one of his letters to Gay, after speaking of Chubb as 'the wonderful phenomenon of Wiltshire,' says of this volume, 'I have read it through with admiration of the writer.' Among the eminent individuals who admired the writings of Chubb, and sought to be of service to him, was Sir Joseph Jekyl, master of the rolls (the early patron of bishop Butler), who appointed him steward, or supervisor, of his house in London; an office of which the duties appear to have been as little suited to the character of Chubb as those of a tallow-chandler. Accordingly some of the witty adversaries of Chubb made themselves extremely merry with the grotesque appearance of his short and fat figure as he officiated at his patron's sideboard, adorned with a powdered tie-wig and a dress-sword. After a year or two he relinquished his stewardship, returned to Salisbury, and to the last 'delighted in weighing and selling candles.' (Kippis's *Biog. Brit.*). His next publications were 'A Discourse on Reason, as a sufficient guide in matters of Religion;' 'On Moral and Positive Duties, showing the higher claim of the former;' 'On Sincerity;' 'On Future Judgment and Eternal Punishment;' 'Inquiry about Inspiration of the New Testament;' 'The Case of Abraham;' 'Doctrine of vicarious Suffering and Intercession refuted;' 'Time for keeping a Sabbath;' and several other tracts upon interesting points of religious dispute. In 1738 appeared his

True Gospel of Jesus asserted.' Chubb would explain what the Christian gospel is, and what it is not: he shows therefore that, as it is said to have been preached to the poor by the founder of Christianity himself and his disciples, antecedently to many transactions of his life, and of course to the events of his death, it could not be a history of his own actions and final sufferings, but was the doctrine of moral reformation which he announced as a rule of conduct, and consequently that the several historical accounts of those transactions and events, with the doctrines founded thereon, are not the gospel, nor any part of it; and, moreover, that nothing is so entirely foreign to its nature and object as the subsequent establishment of state hierarchies, and the metaphysical subtleties since introduced by the political managers of Christianity. In the following year, 1739, Chubb put forth a vindication of this work, and of the discourse annexed to it, against the doctrine of a particular Providence. The following are some of the answers of his opponents: 'Confutation of Chubb's True Gospel,' by the Rev. Jos. Hallett; 'Remarks on Chubb's True Gospel,' by the Rev. George Wightwick, 1740; 'Answer to Chubb's True Gospel,' by a Sufferer for Truth; 'Letter to Chubb on his True Gospel,' by Richard Parker, 1739; 'Remarks on Chubb's True Gospel, and Discourse on Providence,' by the Rev. Caleb Fleming, 1738; 'Remarks on Chubb's Vindication of his True Gospel,' by the Rev. C. Fleming, 1739. To these Chubb replied in his 'Enquiry into the Grounds and Foundation of Religion,' 1740; in which he advocates the priority of a natural religion. This occasioned 'A Vindication of Revealed Religion,' in answer to 'Chubb's Grounds,' by John Phelps, 1740. In 'A Discourse on Miracles,' published 1741, Chubb contends that they furnish no proof of divine revelation. This discourse elicited 'Animadversions on Chubb's Discourse,' by the Rev. C. Fleming; and 'Examination of Chubb's Discourse,' by a Layman, 1742. 'An Enquiry concerning Redemption,' in 1743, and 'Four Dissertations,' in 1746, on portions of the Old Testament history, were the final works of Chubb. The last was answered in 'Truth and Modern Deism at variance, shown by a careful Examination of Chubb's Four Dissertations,' by the Rev. C. Fleming, 1746. In February of the same year, Chubb, according to his desire, died suddenly at the age of 68, as he sat in his chair. Though he left several hundred pounds, his income was to the last so scanty, that it is said he often thankfully accepted from Cheselden, the eminent surgeon, the present of a suit of left-off clothes. His posthumous works, consisting of numerous tracts similar to those already mentioned, were published in 2 vols., 8vo., 1748; and were answered by Fleming, his indefatigable opponent, in 'True Deism the Basis of Christianity; or, Observations on Chubb's posthumous Works.' Dr. Leland, in his 'View of Deistical Writers,' vol. i., has devoted above 80 pages to remarks upon them. For notices of Chubb, see also bishop Law's 'Theory of Religion.' The writer of the article in Chalmers's 'Biographical Dictionary,' in accordance with the proverbial uncharitableness of that work, considers Chubb as an impious and contemptible writer, and wonders how Dr. Kippis could admit the elaborate account of him which occupies twelve folio pages of the 'Biographica Britannica.' The truth is, that, with an occasional blunder, arising from an ignorance of the Greek and Hebrew languages, the writings of Chubb, in following the metaphysical school of Dr. Clarke, exhibit a great argumentative skill, and a style remarkable for a temperate and critical propriety, and a pleasing fluency. The sentiments of liberality and benevolence which pervade his writings, with the zealous endeavour to promote the cause of civil and religious liberty and rational improvement, confirm the opinion which is given of their author by the amiable writer of 'John Buncle,' Mr. Amory, who says, 'I knew him well; he was a sincere good man as ever lived.' The publication, by one of his friends, of 'A Short and Faithful Account of the Life and Character of the celebrated Mr. Chubb,' 1747, drew forth from the Rev. Mr. Horler, of Winchester, a specimen of the most revolting scurrility, entitled 'Memoirs of Mr. Chubb; or, a fuller and more faithful Account of his Life, Writings, Character, and Death,' 1747. The author, after asserting, without the slightest evidence, that Chubb was addicted to the most abominable vices, declares that he would have his corpse, and that of every similar sceptic, instead of being decently buried, 'dragged by a halter round the neck to a gibbet, where the hangman having cut out the heart, plucked out the tongue by the roots, and chopped off the right hand, should burn the whole in a fire made with the books which he wrote; and his ashes being thrown into the air with execration and contempt, would make all those who bow the knee at the name of Jesus, lift up their heads with joy and great gladness.' This work produced 'A Vindication of the Memory of Mr. Chubb from the scurrilous and groundless Calumnies of a late infamous Libel;' 1747. All the above-mentioned works are in the library of the British Museum.

CHUDLEIGH. [DEVON.]

CHUMPANEER, a subdivision of the province of Guzerat, situated between 22° and 24° N. lat., and between 73° and 75° E. long. It is bounded on the north by the river Mahy or Mhye; on the south by the Nerbudda; on the east by Malwa; and on the west by the district of Baroach. This territory is principally possessed by the British government and the Guicowar, but on the decline of the Mogul empire, some portion, including the town of Chumpaneer, fell into the hands of the Mahrattas, and there are besides a few petty chiefs, or Rajahs, who acknowledge a limited kind of dependence upon the actual possessors of the sacred mountain upon which the antient town and fortress of Chumpaneer were built. This mountain rises out of an extensive plain to the height of about 2500 feet. Chumpaneer is described by Abul Fazl 'as a fort upon a lofty mountain, the access to which, for upwards of two cose, is exceedingly difficult, and there are gates at several parts of the defile.' The cose is explained by the same author 'to consist of 1000 steps made by a woman carrying a jar of water on her head and a child in her arms.' At the northern base of the mountain are the remains of a city, supposed to have been the capital of a Hindoo principality before the Mohammedan invasion. The city was taken in the year 889 of the Hegira, answering to 1485 of the Christian æra, by Mahmood, the Mohammedan ruler of western Guzerat. Half a century later it was taken by the emperor Humaiyoon, and when described as above by Abul Fazl in 1582 consisted principally of Hindoo and Mohammedan ruins. The town does not contain at present more than between 200 and 300 inhabited houses, but the ruins of antient buildings extend for several miles on each side of the mountain: there are two forts on the mountain; the upper one is considered to be of great strength.

(*Ayin i-Akbari*; *Report of Committee of House of Commons of* 1832, political division.)

CHUQUISACA. [BOLIVIA.]

CHUQUISACA, the capital of Bolivia, in South America, is situated near 19° S. lat., and between 64° and 65° W. long. It lies in one of the valleys which descend from the eastern declivity of the eastern chain of the Bolivian Andes, at an elevation of about 14,700 feet above the level of the sea; to which circumstance its delightful climate must be ascribed. This valley contains the Cachimayo, a tributary of the Piciomayo, which is a branch of the Paraguay river. The town, which was formerly called Charcas, or La Plata, and, at a certain period of the war with the Spaniards, Sucre, from the name of the general who gained the victory of Ayacucho, is on the whole well built, and has a magnificent cathedral, with large towers rising from each angle. There are also several churches and convents, with domes and steeples, which from a distance give it the appearance of a large town. But the place is of moderate extent, having only a population of 26,000. It has an appearance of neatness and cheerfulness, not very common in the towns of South America. Since it has become the seat of the legislature and government of the republic, great changes have been effected. The palace in which the archbishop of Charcas once resided has been assigned to the president of the republic. Some of its well-built convents have been converted into institutions of education, one having been given to the university, and another turned into a mining-school and a college of arts and sciences, both of which were founded in 1826. (General Miller; Temple.)

CHURCH, or KIRK, which is precisely the same word in a varied orthography, is supposed to be the Greek word κυριακός (kuriakos), a derivative of κύριος (lord), one of the designations of Jesus Christ, the founder of the Christian system. It is one of the Saxon adoptions from the Greek. Κυριακός is an adjective, and we must understand after it some word denoting flock, or house, the Lord's flock, the

Lord's house; the two senses in which kirk, or church, is used.

Of church, as denoting an edifice appropriated to Christian purposes, we treat in a separate article. We have now to speak of it as a term used to designate bodies or communities of men, when contemplated under the aspect of being persons who are followers of the Lord Jesus Christ. We shall endeavour to exhibit and illustrate the various senses in which it is used with as much completeness as our limits will allow. The word church has been used from the most remote period to represent the Greek term ἐκκλησια (Ecclésia), which often occurs in the New Testament, which was adopted into the Latin language without any change, and which gives us our words ecclesiastics and ecclesiastical, which correspond to the Saxon terms churchmen, and of churchmen. The meaning of the word *ecclesia* among the classical Greek writers is 'meeting or assembly,' and in this or the somewhat modified sense of 'community' it was adopted by the writers of the New Testament.

The whole community of Christians thus constitute the church. This is the sense in which the word is most commonly used in the New Testament: as when it is said that 'the Lord added daily to the church such as should be saved' (Acts ii. 47); 'Head over all things to his church' (Eph. i. 22); 'concerning zeal, persecuting the church' (Phil. iii. 6): and when our Lord said, 'Thou art Peter, and on this rock I will build my church' (Matt. xvi. 18), he contemplated that majestic assembly, the multitude, whom no man can number, who in ages to come should form the great Christian community. And as, when thus used by the Apostles, it comprehended all the disciples of Christ, without regard to questions which divided the opinions of Christians even in the earliest times, so it is still often used to denote the whole body of Christians, notwithstanding any peculiarities in their church-order and ritual, or however they may understand the instructions on some points of Christ and the Apostles.

But it soon came to be regarded as essential to the idea of a church that the believers should be bound together by a species of mutual pledge, and form a compact and united body. Certain outward forms of profession came to be regarded as requisite for every member, such as baptism, and partaking in the Lord's Supper; certain officers, as bishops, pastors, and deacons, were regarded as essential; as well as certain uniform services, and the acknowledgment of certain propositions as containing a just exposition and summary of the doctrine of Christ and the Apostles. A continued effort seems to have been making from a very early period in the history of Christianity to bring the body of professing Christians into this state of consistency and uniformity. And to give the greater effect to the effort, the bishop of Rome, who was represented as the direct successor of St. Peter, the rock on whom the church was to be built, received by almost universal consent a kind of headship, or supremacy, and about him was gathered a council, consisting of other bishops, pastors, and deacons, forming a supreme authority in this compact community, and a court of ultimate appeal. Nearly the whole body of professing Christians in the states of western Europe were, by various means, brought to enrol themselves in this great confederacy, and they formed for many ages the church, a numerous and in the main a well-ordered and well-governed community.

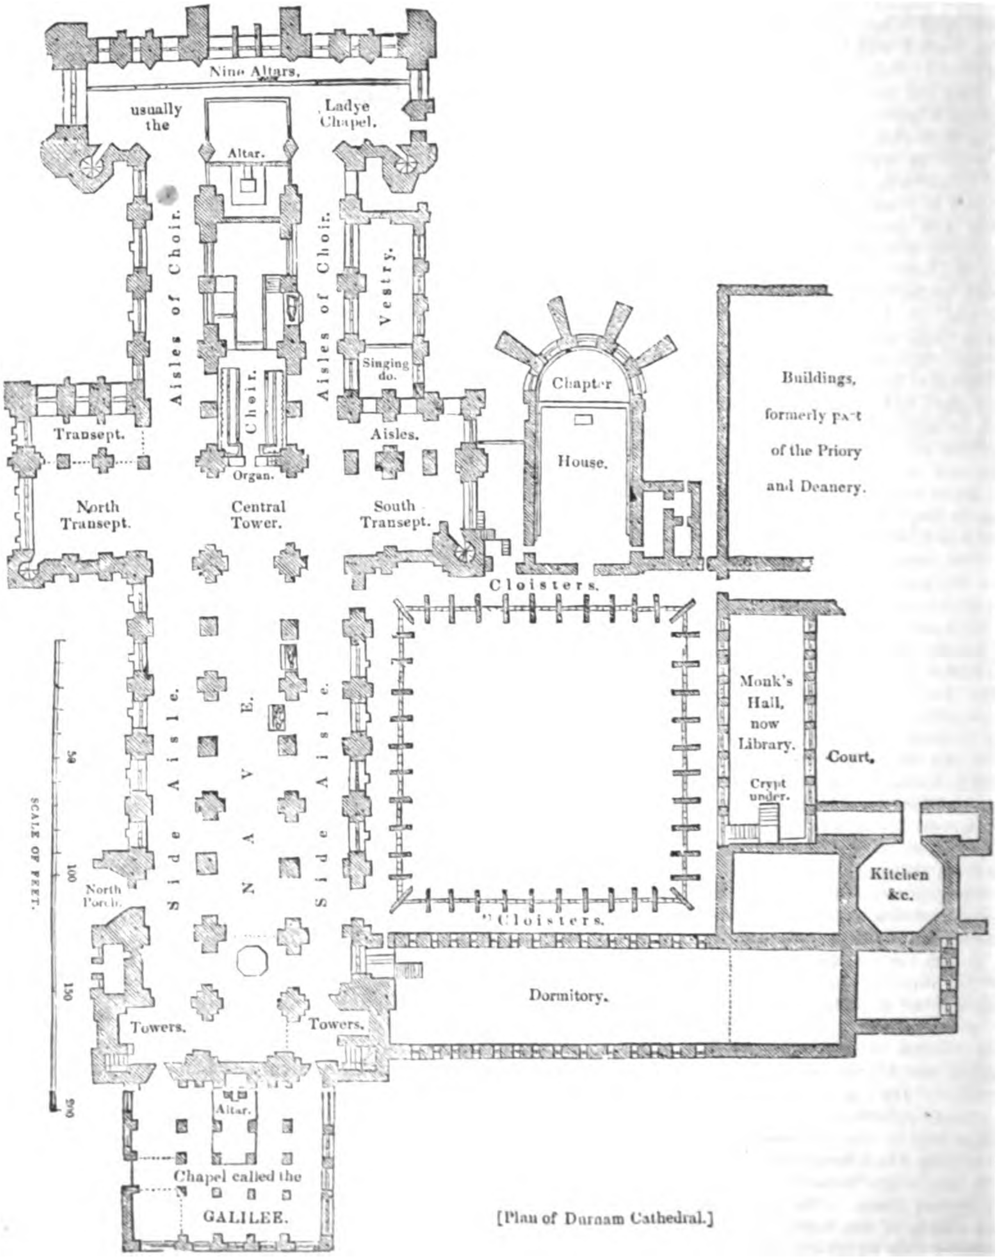
At the Reformation, certain states of Europe separated themselves from this great community of Christians. The separation was made on various grounds: objections to the tyranny of the ecclesiastical authorities; to their exactions; to their assumption of powers not sanctioned by reason or Scripture; to the corrupt lives of some of the persons near the head of the church; together with an opinion that the ceremonies enjoined in the rituals were superstitious, if not idolatrous; and that many things were taught to the people as Christian verities which not only had no countenance from Scripture, but which were opposed to the plain teachings of Christ and the Apostles. Many of the more learned and more virtuous reformers did not look to the breaking-up of the church, but to the reformation of it in doctrine and discipline, leaving the community of believers in the compact and, in the main, beautiful consistency and order in which they found them. But the resistance which was made to the efforts of the reformers, combined with other things, rendered this impracticable, and nothing remained for the states in which the call for reformation was the loudest, and where a strong sense of the corruption of the Roman Catholic system had possessed the minds both of rulers and people, but to break off from the great confederacy, and to renounce entirely all connection with and all spiritual allegiance to the pope, the great head of the church. Hence arose another use and application of this term *church*, and we hear of the church of Geneva, the church of Scotland, and the church of England, meaning the Christian members of those political confederacies, or belonging to those nations, when regarded under the aspect of being professed believers in Christ.

The expediency and the right of particular nations thus to detach themselves from the great community of Christians, and to establish churches of their own, have been the subject of controversy. The Protestant, however, regards the point as settled, and in each of the three states above mentioned, as well as in other Protestant states of Europe, there are *national churches* established, founded on the public law, and regulated by the same public will which regulates affairs purely political and secular. Those national churches of Protestantism vary among themselves on almost every point both of order, ritual, and doctrine, according to the peculiar opinions of the persons who happened to possess the chief influence at the time when the new faith, form, and order were established, or who at a somewhat later period had influence sufficient to modify the church in any of those points. Hence there is no common church of Protestants. Each Protestant nation has its own church, and regulates its own spiritual affairs without communication with other Protestant people. It is a system of national independency. These national churches, however, are not found to comprehend all persons who in their political character are members of the respective nations. In the English, the Scottish, and other Protestant nations, there are many persons who continue to profess that they adhere to the antient and great community, that they are members of the Christian church in the second of the senses of which we have spoken, and who abstain from connecting themselves in any manner with the national church, having their own system of faith, worship, and order as a branch of the great catholic or universal church. Again, there are a great multitude of Protestants who do not regard themselves as members of the church of England or of the church of Scotland; some who object to the frame and order of the church as in England being episcopal, and in Scotland being presbyterian; some who have scruples respecting points in the public service book of the church of England; some who regard the Articles of Faith as not presenting a just view of the doctrine really taught in Holy Scripture; some who think that the church as at present constituted does not leave the ministers sufficiently at liberty for the influential performance of their duties; and some who think that practically the system is not favourable to the prevalence of Christian influences, which they regard as the main object in every appointment connected with the church. We touch but upon the broad and leading objections. But there are many also who separate themselves from the national union because they object to the principle of a national church. They contend that there should be no such church regulated by councils and parliaments, but that the believers in Christ should be left at entire liberty, each person for himself to connect himself with others, if he see proper to do so, and thus to form Christian communities on principles and for purposes such as each individual might approve for himself. The Congregationalists or Independents of England, the most numerous class of English dissenters, in the declaration of their faith, church order, and discipline, issued by authority in 1833, avow the principle that each society of believers associated together for religious purposes is properly a Christian church. The question about which there has been so much disputation, of the union of church and state, is in effect, and when stripped of its abstraction and its personification, nothing more than the question whether there shall be a union of the people of each nation in one Christian society, the affairs of which are regulated by the national will as that will is collected on other subjects; or, whether there shall be no expression of a common will, but each person be left to receive or neglect Christianity, and to make his public profession of it in whatever way seems to him to be best. Our limits do not allow us to enter into the discussion of this question, but we may state the main arguments briefly thus:—In behalf of a national church it is contended that without some public provision there would soon be many parts of the country without Christian ministrations at all; that by securing an order of well-instructed ministers, there is the best preservative that can be devised against the prevalence of injurious superstition and dangerous errors; that affairs of such importance as these should be subjected to the consideration and direction of the enlightened mind of a people; and that practically from the moment that property is acquired by any body of professing Christians, that body must become amenable to the state, must apply to the state for direction whenever questions arise respecting it, so that it is in fact impossible entirely to disjoin affairs of religion from affairs of state. On the other hand, it is contended that to set up articles of faith and forms of worship is an injurious invasion of the rights of Christians; that to connect the profession of particular opinions with temporal advantages is unfavourable to the progress of inquiry and of truth, and has a tendency to produce simulation in Christian ministers; that the system leads to political subserviency, and fosters a worldliness of spirit; and that practically the system is not acceptable to the nation, as is evinced by the multitude of the persons who, notwithstanding the losses and inconveniences to which in consequence they subject themselves, yet do not belong to the church.

The Methodists do not, we believe, speak of themselves as a church; but their system is in all its great features that of a Presbyterian church.

We have now gone through the principal senses in which this term *church* is used when it is applied with any propriety. But we cannot conclude without noticing one other sense in which the word is often used, and we notice it to condemn it as mischievous, and in every point of view incorrect and improper. We mean when *church* is used to denote *the officers of the church*, the bishops, priests, and deacons; a use of it neither sanctioned by etymology nor the usage of primitive times, and which is calculated greatly to mislead, as things which are predicated, and truly predicated, of the church in its proper sense of a community of believers in church order, and appointed with proper church officers, may be transferred inadvertently to *church* when it is the officers only who are meant. 'The interests of the church,' for instance, a very common phrase, are properly the interests of the great English community looked upon in the aspect of its relation to Christianity, not the interests of the officers or ministers only. Their proper designation is not the church, but the clergy.

CHURCH. An ecclesiastical edifice, sometimes built after the model of a modern basilica, and sometimes in the form either of a Latin or a Greek cross. The basilica form however must be considered as belonging to the churches



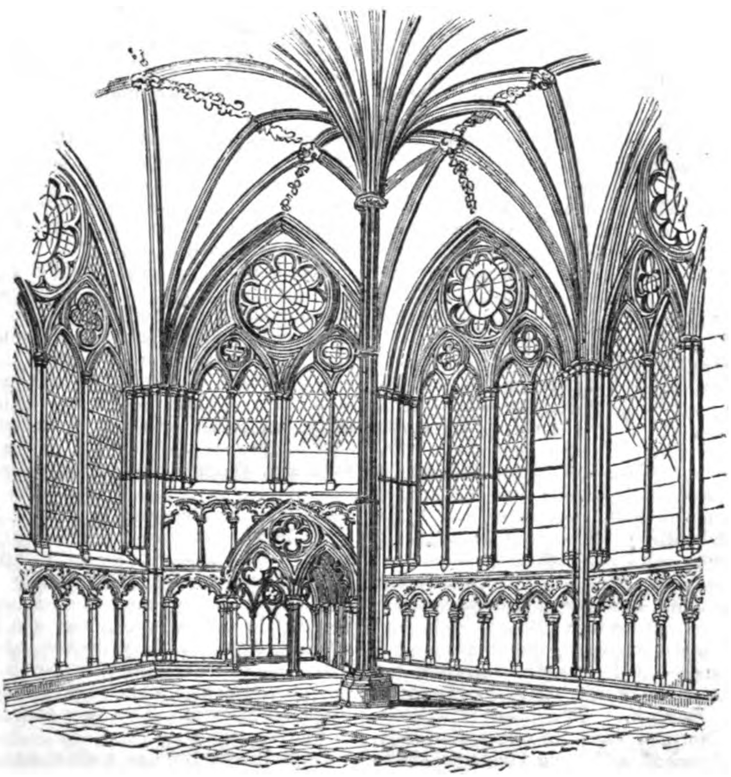
[Plan of Durham Cathedral.]

of the early Christians. The origin of the difference between the form of the Latin and Greek cross belongs to the period of the schism in the church. The Latin was in common use until the Reformation. Some resemblance to the basilica form may be traced in modern churches erected since the Reformation to the present day. The most perfect resemblance to the church basilica is observable in the cathedrals of Europe, and especially in England. Attached to these edifices there are still many of the various buildings which formed the monastic establishments of former days. A church or cathedral with a Greek cross has the transept as long as the nave and choir: the greater part of the Greek churches are built in this form. The Latin cross has the nave much longer than the transepts and choir. Many of our modern churches consist of only one long nave, with an altar at the east end: the cross form, or transept, is in some instances scarcely perceptible, and in others entirely omitted. In the nave of the church, towards the east end, are placed the pulpit and reading-desk, sometimes on one side, and sometimes in the centre of the nave. A sounding-board is often constructed over the pulpit in order to assist the voice of the preacher. The altar end of the church is raised by a step or steps, and is enclosed. The font is sometimes placed near the entrance and at others near the altar; and the stoups, or small stone basins, set in niches and originally intended for holy water, are often seen in village churches. At East Dereham these stoups are on the exterior of the porch. Near the altar in antient churches there are sometimes three niches with seats in them raised each a step above the other.

Churches are of five classes, metropolitan, cathedral, collegiate, conventual, and parish churches. The term cathedral is derived from καθίδρα, 'a seat,' from the seat or throne of the bishop being placed therein. Cathedrals are the chief ecclesiastical structures of the dioceses in which they are situated.

Almost every cathedral is varied in plan, although the leading features, the nave and choir, are found in almost all. The plan usually consists of a galilee, or chapel, at the principal entrance; the nave, or main body of the church; the side aisles, which do not rise so high as the nave, and are placed on each side of the nave, sometimes with chapels, at other times without, between the openings formed by the windows; the choir, or place for the ceremonies of the church; the transept, or division at right angles to the end of the nave next the choir, which projects on each side, and forms a cross on the plan. Some cathedrals have a double transept, and the transepts have often aisles. At the end of the choir is the high altar, behind which is usually a ladye chapel, or chapel to the Virgin. The choir end of a cathedral is sometimes terminated by an apsis, or semicircular end. The term apsis was originally applied to the whole choir, or part railed off from the nave, like the end of a church basilica. Along the sides of the choir are ranged richly-carved seats, ornamented with arches, pinnacles, and tracery, carved in oak. The bishop's seat, richer than the others and raised above them, is on one side, at the eastern end. The choir has also side aisles. Cloisters and a chapter-house are usually attached to English cathedrals, but the latter are rarely met with on the continent, the chapters being usually held in the cathedral, or in a chapel within the cathedral or abbey. The minor parts of a cathedral are the muniment room, the library, the consistory court, the vestries of the dean and chapter, minstrels' chapels, a font, and a minstrel's gallery.

Beneath the body of the cathedral there is usually a crypt, or low basement, supported on arches springing from thick columns, as in Canterbury cathedral and others. Both externally and internally the antient cathedrals of England, France, and Germany display all the luxury of Gothic architecture. Like all ecclesiastical buildings, they stand with the altar towards the east, and the principal entrance to the west; the transept is placed north and south. At the point of intersection of the transept with the nave there is usually a lofty tower, sometimes surmounted by an elegant spire, as in Salisbury cathedral. Sometimes the principal or western front has a tower at each angle, which in some instances are also terminated with spires. The nave of a Gothic cathedral is supported by clustered columns, arched from one to the other, over which there is usually a row of small arches forming a gallery, which is called the *triforium*, and above are windows called clere-story windows. The aisles are lighted by windows placed between the openings of the arches of the nave; and, externally, the buttresses of the aisles often rise, supported on an arch, to the wall of the nave: these are called flying buttresses. The exterior walls of the cathedral, with its towers, are generally decorated with buttresses, surmounted with pinnacles; and between the buttresses are the openings or windows of the nave and aisles. The ceiling of the nave is sometimes of stone, and covered with tracery formed by the intersection of the arches which spring from the clustered columns of the



[Chapter-house, Salisbury.]

nave. The west or principal front is usually the most highly decorated with tracery, pinnacles, and sculptured figures. In the side aisles, and the aisles of the choir, there are often chapels richly designed, which contain the tombs of the founder, &c. Our cathedrals abound with monuments of various epochs, from the early Norman period of our history to the present time. The chapter-house and cloister are large and important features in many of our cathedrals. The finest chapter-houses in England are of a polygonal form on the plan, with a seat running round from the entrance, and the interior decorated with sculpture, and in some instances with painting. In some chapter-houses a column, or cluster of columns, rises from the centre of the room, from which spring the sides of pointed arches, meeting the other halves of pointed arches rising from the column or columns at the angles of the walls.

The chapter-house of Salisbury cathedral contains some of the finest specimens of the kind of sculpture usually found in such buildings.

The cloisters are rectangular enclosures, with a richly-ornamented and arched gallery running round the sides, and a wall forming the back of the enclosure: the arches, which are filled with tracery, look into an area, where probably the monks were formerly buried. There are also cloisters in some of the colleges of Oxford and Cambridge. The cloisters seem to be very similar to, and perhaps derived from, the crypto-porticus of antiquity. [Chalcidicum.] The Campo Santo at Pisa appears to have been originally a large cloister, similar to our cathedral cloisters. This part of the ecclesiastical structure may have been used not only for exercise, but for study. In England the cloisters were probably glazed: in Italy they are often decorated with frescoes, by celebrated masters. Chantries, or chapels for singing mass, were formerly founded by the pious for the benefit of their souls. They are often placed between the pillars of the nave, as the chantry of Cardinal Beaufort at Winchester: the effigy was also placed within the chantry. Some are complete chambers formed in the aisle of the choir as at Ely, and others are independent of the cathedral, as at Westminster. In some antient and modern cathedrals and large churches the principal feature is a dome, as St. Sophia's at Constantinople, St. Paul's, London, St. Peter's at Rome, and St. Mark's at Venice, Santa Maria de' Fiori at Florence, the Pantheon at Paris, and many others.

Some parish churches have very much the form of a cathedral, as Christ church, Hants. The chancel of a church, which is often the property of a layman, corresponds in situation to the choir of a cathedral, and, like it, is railed off from the body or nave of the church. [Chancel.] The chancels of our churches often contain the monuments of individuals connected with English history and literature, as at Arundel church, and Stratford-upon-Avon. In parish churches however the great tower is seldom placed at the intersection of the nave and transept, but forms the entrance at the west end, and contains the belfry. One of the most antient and best preserved parish churches in this country is St. Cross at Winchester. Norfolk and Suffolk possess many fine churches, some of which are remarkable for the lightness of their construction. (*Views of Collegiate Churches*, by J. P. Neale; Ferrey's *Christ Church, Hants.*)

The antient cathedrals of England are Bristol, Chichester, Canterbury, Carlisle, Chester, Durham, Ely, Exeter, Gloucester, Hereford, Lichfield, Lincoln, Norwich, Oxford, Peterborough, Rochester, Salisbury, Wells, Winchester, Worcester, and York. St. Paul's, London, is modern. Besides these there are several edifices, called minsters, which possess a cathedral character both in their construction and in their uses, as Westminster, Beverley-minster, and Lichfield and York cathedrals, which still retain the name of minster. Abbey churches had also a cathedral character.

The cathedrals of Norwich, Westminster, Canterbury, Peterborough, and Gloucester, have a semicircular apsis.

Ely has a centre tower and lantern 170 feet high, and a fine tower at the western entrance, much higher: it had two towers at the angles of the western entrance, but only one remains. The style of the building externally is Norman and early English. The nave is a beautiful specimen of the Norman style, the elevation consisting of three tiers of arches, with long clustered shafts round each pier. The elevation of the choir internally presents a superb design of decorated English. It was erected, with the equally beautiful chapel of St. Mary, between the years 1321 and 1349. The tower and lantern, supported on eight large piers, were unique until the erection of St. Paul's. Ely lantern is said to have suggested to Sir C. Wren the idea of the lantern over the dome of St. Paul's. This cathedral has the ladye chapel at one side, and not at the east end.

Salisbury is in many respects one of the finest English cathedrals, and the most uniform in style. It has two transepts. The ladye chapel has been, perhaps injudiciously, thrown into the choir. There is a porch entrance on the north side, leading into the nave. The cloisters, which are very extensive and magnificent, lead into a very elegantly-designed chapter-house. There is a small muniment-room attached to the south end of the second transept. The tower is supported by four massive piers, surrounded with smaller columns: the tower is surmounted by a spire; the whole height is 404 feet. This spire was added some time after the tower was finished; and the weight of it has considerably warped the piers, in consequence of which the summit of the spire is near two feet out of the perpendicular.

Hereford cathedral has a nave, side aisles, a north porch, two transepts, a choir, a ladye chapel, cloisters, and a chapter-house. The nave and chapter-house are in ruins. The architecture of the nave is Norman. The east end is built in the early English style. Underneath the ladye chapel is a crypt; and at the intersection of the nave there is a very large square tower.

Worcester cathedral is very similar in plan, having two transepts, but no side aisles to the larger transept which intersects the nave. The chapter-house and cloister are situated like those of Hereford; and at the intersection of the nave there is a handsome tower. The interior of the nave is in the early English style. The chapter-house is in the Norman style.

Wells cathedral, in plan, differs very much from all the rest. The chapter-house is on the north side of the church; the cloisters are in the usual place, the south, but they have only three sides; the entrance to them is from under the south-western tower of the cathedral. Here we have two western towers, a north porch, and a transept, with side-aisles; and at the end of the choir a very elegant ladye chapel, with a termination at the east end, somewhat similar to the apsis of a basilica. The architecture of the nave is early English: the towers appear to be much later in style. There is a crypt under this cathedral.

Exeter cathedral, founded in 932, rebuilt in 1112, has a chapter-house, used as a library, in the form of a parallelogram, unlike the usual form, which is polygonal. The cloisters of this cathedral were destroyed during the Commonwealth. The singularity of the design of this edifice consists in its having two towers, in the Norman style, one at the north and the other at the south end of the transept. The nave is very fine, and in the early English style.

Bristol cathedral, founded about 1142, is inferior to many others: it is irregular and imperfect in the plan, being without a nave. There is however some curious Norman work in the chapter-house.

Peterborough cathedral, rebuilt 1117, is on the plan of a simple Latin cross, with one large and two small towers at the western end, terminated with spires. The altar end of the choir has the termination in the form of the antient apsis: the ladye chapel is behind the altar. The transept has side-aisles and a tower at the intersection with the nave. The west end is remarkable for three large arches, under the centre of which is a small porch, with a library over it. The style of this cathedral is partly Norman, mixed with early English. Some parts are of a later date, as the east end, which is in the perpendicular style, or that kind which has been termed Tudor.

Gloucester cathedral, rebuilt 1089, differs from the preceding. The apsis is very large: attached to this part of the building, and at the entrance of the side-aisles, are chapels: the ladye chapel extends backwards. The chapter-house and cloisters are on the south side. On the north side of the cloister is a projection called a lavatory. On the south side there is a beautiful porch. An elegant tower, in the perpendicular style, rises from the intersection of the nave and transept. The walls and columns of the nave are in the Norman style.

Oxford cathedral has a short nave, a choir, a north transept, with an aisle, longer than the south transept, which is without aisles. Two large chapels on the sides of the choir cloisters, and a rectangular chapter-house, are attached on the south side.

Hereford cathedral has an aisle, a north porch, double transepts, a choir, ladye chapel, cloisters, and remains of an octangular chapter-house.

Carlisle cathedral, formerly a priory, is small, and inferior to the other cathedrals.

Chichester cathedral has a nave, side aisles, transept, a choir, ladye chapel, now a library, and an irregular enclosed cloister. There is also an isolated bell-tower, like the Italian campanile in principle. This cathedral has an elegant spire.

Chester has a nave, side-aisles, and south transept, now a parish church; a choir and ladye chapel at the east end; a cloister to the north, and a rectangular chapter-house, and school-room, to the north of the cloister.

Lichfield has a nave and choir, nearly the same length; a ladye chapel, with a semi-octangular head or apsis; an aisle on one side of the transept; and a chapter-house with parallel sides terminated at two ends with semi-octangular figures.

Canterbury has a nave, and a cloister on the north side leading to the chapter-house, which is in the form of a parallelogram; double transepts, choir, and side chapels. At the end of the choir is an elegant chapel, with an apsis, and a circular chapel beyond, called Becket's Crown. The font is in a circular chapel, leading from the north transept. To this building is attached a library. The crypts underneath the entire cathedral are the finest in the kingdom. There are three towers, one in the centre, and two at the west end.

York is on a very elegant plan. The transept has double aisles; there is an elegant octangular chapter-house leading from the north transept, a superb centre-tower, two western towers, a record-room, and consistory-court. There is also a small crypt.

Winchester has a regular plan: the cloister was rectangular, but both it and the chapter-house have been destroyed. The transept is remarkable and unique, on account of the aisles running round the three sides. A small ladye chapel is attached to the east end, and there are extensive crypts under the cathedral.

Lincoln has a nave, a choir, and double transepts. Behind the choir is a place called the Presbytery: a small galilee is attached to the south transept. The cloister, which is comparatively small, leads to a magnificent chapter-house, of a polygonal figure, ten-sided, with flying buttresses. The western transept has aisles, and a large tower at the intersection with the nave. At the west entrance there are two smaller towers. Lincoln cathedral is very perfect.

Norwich has a long nave, and one transept; the east end is terminated by an apsis, beyond which there is a ladye chapel, and at the side of the apsis two chapels, formed by two segments of a circle. Attached to the side-aisle of the choir is a consistory-court. There are large cloisters on the south side of the edifice. The chapter-house has been destroyed.

Worcester cathedral has a nave and side-aisles, north porch, double transepts, choir and side-aisles, and a ladye chapel. On the south are the cloisters and king's school, and a chapter-house, circular within, and polygonal on the outside, with a column in the centre, as at Lincoln and Salisbury.

Westminster has a long nave and transept, with double aisles, an apsis at the east end of the choir, with four semi-polygonal chapels round it: beyond is the sumptuous ladye chapel built by Henry VII. The cloisters are to the south, as well as the chapter-house, an octangular building; beyond are some smaller cloisters connected by dark passages with the great cloisters. (See the plan in the *History of St. Peter's Church, Westminster*, by J. P. Neale.)

Rochester has a nave and side-aisles, a double transept, but on the north side of the choir only, a choir, and a chancel at the end of it. The chapter-house is at the south-east, and in form is a long parallelogram. A low tower rises from the intersection of the transept and nave, and on the west is a chapel.

Bangor cathedral consists of a choir, nave, transept, aisles, and a quadrangular tower at the west end. The clere-story windows are circular: those below are pointed.

Bath abbey, now a cathedral church, is in the form of a cross, making two small transepts without aisles; a small vestry is attached to the south transept, and a great tower rises at the intersection of the transept. The choir is the same width as the nave.

The cathedral of St. David's is partly Norman and partly of the pointed style. It consists of a nave, choir, transepts, side aisles, and a western tower. For a brief account of the cathedral of St. Asaph, see **St. Asaph's**.

A comparison of the principal Measurements of the English and Welsh Cathedrals, except St. Asaph's and Llandaff.

The above are taken from Britton's 'Architectural Dictionary;' Neale's 'Westminster;' Browne Willis's 'Survey of the Cathedrals,' and 'History of the Mitred Parliamentary Abbeys;' and Dugdale's 'Monasticon.' For more minute admeasurements, see the works quoted at the end of this article.

The numerous cathedrals of France, Italy, and Germany present beautiful specimens of architecture, not only in the Gothic style, but also in the Italian style. The cathedrals of Amiens, Beauvais, Nôtre Dame de Paris, as well as others, are beautiful examples of Gothic. Cologne, and Freiburg, in the Breisgau, are equal if not superior to any cathedral in England. The cathedral, or Duomo, at Padua is partly in the Italian style, and the western front, though perhaps not in correct taste, produces a masterly effect. St. Peter's is the largest cathedral in Europe. Vienna and Strasburg have the highest spires; the former is 465 feet, the latter 456 feet high. (For information on English cathedrals we must refer the reader to Britton's *Cathedrals*, seventeen of which have been treated by him in separate publications, beautifully and correctly illustrated; Bentham's *Ely*, and Miller's *Ely*; Dugdale's *Monasticon*; Dodsworth's *Salisbury*; Wild's *Lincoln and Worcester*; Browne Willis's *Survey of the Cathedrals*.)

CHURCH, STATES OF THE. [Papal States.]

CHURCHILL. [Marlborough.]

CHURCHILL, CHARLES, was born in 1731, in Westminster, where, in St. John's parish, his father was curate. After accomplishing the usual period of grammatical studies in Westminster School, he was taken by his father to Oxford to be matriculated in that university: but his volatility and vivacity of imagination, which already had prevented his becoming distinguished in the scholastic routine, occasioned his rejection at the entrance examination. It is said that the sage solemnity of the examiner's visage, arrayed in a large bushy wig, contrasted so strangely with the frivolous grammatical questions proposed for solution, that Churchill imprudently indulged in a fit of laughter; and instead of making the proper replies, he aggravated the indecorum of his conduct by making facetious and satirical remarks, and proceeded to interrogate the examiner on which, of course, he was dismissed with indignant displeasure. He was shortly after admitted a member of the university of Cambridge, where however he took no degree, but soon returned to Westminster, where he became passionately attached to a young lady of the name of Scott, whom, although he was but in his seventeenth year, he precipitately married, without any means or plan of subsistence. After a year's residence in his father's house, he retired with his wife to Sunderland, and prepared for taking orders. At the age of 25 he was ordained by bishop Sherlock, who is said to have exclaimed, 'Good God! before what sort of an examiner must this gentleman have been, when he was pronounced to be deficient in scholastic education?' Most of his biographers state that he now repaired to a curacy in Wales of 30*l.* a year, and that in order to provide for his family, he sought to augment this miserable pittance by fitting up a cider-cellar, and undertaking to supply this article to the neighbourhood; a project which terminated in his becoming a bankrupt. But this statement is contradicted by the editor of his works, published in 1804, who asserts, in a prefixed biographical account, which appears to be collected from authentic documents, that Churchill went at this period to officiate in the curacy of Rainham, in Essex, previously held by his father, and that he there opened a school. It is probable that the cider story may have arisen from some confused relation of the fact that Churchill was first ordained deacon on the small curacy of Cadbury, in Somersetshire, which, as being not far from Wales, and famous for cider, presents sufficient data for the makers of marvellous and interesting anecdotes. In 1758, on the death of his father, he succeeded to the curacy of St. John's, in Westminster, and from this period a total alteration took place in his character and habits, which, from having been hitherto those of a moral, domestic, and studious man, became gradually ruined, and terminated in avowed and abandoned licentiousness. This change may be attributed to his intimacy with the talented and profligate poet, Robert Lloyd, whose father, Dr. Lloyd, a master of Westminster school, about this time interposed as the friend of Churchill, and rescued him from jail by advancing to his creditors a composition of five shillings in the pound; but, to the credit of Churchill, it must be added, that he himself subsequently paid the whole amount. His first poems were 'The Bard' and the 'Conclave,' for which he was unable to obtain a publisher. 'The Rosciad,' a very clever and severe satire upon the principal theatrical managers and performers at that time, was published in 1761, at his own risk; the London publishers having refused to give five guineas for the MS. It obtained an amazing popularity, and was answered by the numerous parties attacked in Churchilliads, Murphyads, Examiners, &c. The subject is one on which the author, as a poet and constant play-goer, was well qualified to express a critical judgment. Like most of Churchill's productions, it is more remarkable for energy and eloquent roughness of sarcasm, than for polished phraseology or refined sentiment. His next poem, 'The Apology,' written in reply to his critical adversaries, is perhaps the most finished and correct of his works. The poem called 'Night' was intended as an apology for his own nocturnal celebrations of the rites of Bacchus. These orgies, in which Churchill was associated with the convivial wits of his time, Colman, Thornton, &c., are well described in Charles Johnson's 'Chrysal; or, the Adventures of a Guinea.' The argument of the 'Apology' is bad enough; showing only that the open avowal of vice and licentiousness is less culpable than the practice of it under the hypocritical assumption of sanctified temperance. 'The Ghost,' a poetical satire on the ridiculous imposture of Cock-lane, served but little to increase the literary fame of its author. With the exception of a few well-delineated characters, it is a series of rugged Hudibrastic incongruities. 'Pomposo,' in this poem, is intended for Dr. Johnson, who had designated Churchill 'a shallow fellow.' In 1762 Churchill became acquainted with John Wilkes, and contributed to the pages of the 'North Briton.' To gratify his political patron, he wrote 'The Prophecy of Famine; a Scots Pastoral,' which was greatly extolled, not only by Wilkes, and the politicians of his party, who said it was 'personal, poetical, and political,' but by the literary public. The editor of the last edition of Churchill's works declares it to be 'one of the most admirable specimens of satirical composition in the English language.' There is much humour in the following imitation of Virgil's 'Ante leves ergo pascentur in æthere cervi,' &c. (*Eclog.* 1.)

'Ah, Jockey, ill advisest thou, I wis,
To think of songs at such a time as this.
Sooner shall herbage crown these barren rocks;
Sooner shall fleeces clothe these ragged flocks;
Sooner shall want seize shepherds of the south,
And we forget to live from hand to mouth.'

The praise and profit which Churchill obtained by this jeu d'esprit seem to have overwhelmed his common sense: he plunged at once into the greatest irregularities of conduct, which drew from his parishioners a serious remonstrance, and induced him to relinquish the clerical profession. At the same time he quarrelled with and separated from his wife, who herself is said to have been any thing but a prude. The utter recklessness of his conduct at this period is shown by his seduction of a tradesman's daughter in Westminster, whom he shortly afterwards abandoned. His poem called 'The Conference' was composed whilst he seemed to suffer some feelings of contrition. A published letter to one of his friends on the occasion of his quitting his profession and his wife, contains the following assertion:—'I have got rid of both my causes of complaint—the woman I was tired of, and the gown I was displeased with. I find no pricks of conscience for what I have done, but am much easier in my mind. I feel myself in the situation of a man who has carried a d——d heavy load a long way, and then sets it down.' After throwing aside his clerical habit, he appeared in a blue coat, gold-laced waistcoat, large ruffles, and a gold-laced hat. His satirical 'Epistle to Hogarth' was revenged by the artist's caricature of 'The Reverend Mr. Churchill as a Russian bear' in canonicals, holding a club and a pot of porter, with a pug-dog which is treating the poet's works with great indignity. We have still to mention several poems, all of which are more or less satirical; namely, 'The Duellist;' 'The Author;' 'Gotham;' 'The Candidate;' 'Independence;' 'The Journey;' and 'Farewell.' Of these, 'The Author' is by far the most pleasing: the satire is general, and delineates with great effect the prim pedantry of collegiate life. 'The Candidate' is replete with poetical fire and spirit. 'Farewell' is comparatively tame, and 'Gotham,' which was written during a short fit of retirement and reformation, is chiefly descriptive. Churchill was a close and occasionally a very successful imitator of Dryden. His verses have much of the fervour and force of this great poet; and at the same time all the coarseness and ruggedness of Donne and Oldham. He has been styled the bard of liberty, and the scourge of tyranny. He was frank, sincere, and generous to a fault; and apparently not naturally vicious, but the unfortunate victim of dissolute companions. Cowper, in a long passage in his 'Table Talk,' assigns him, on the whole, a distinguished place as a poet, calling him a 'spendthrift alike of money and of wit.' He died at Boulogne, in 1765, while on a visit to Wilkes, his intimate friend. His complete works were published in 8vo., in 1804, with a life and portrait. Some interesting particulars are given in 'Genuine Memoirs of Mr. Churchill,' 12mo., 1765.

CHURCHWARDENS are parish officers, who by law have a limited charge of the fabric of the parish church, of the direction and supervision of its repairs, and of the arrangement of the pews and seats. Certain other duties are imposed upon them on particular occasions. There are usually two churchwardens in each parish, but by custom there may be only one. It is said by some authorities, that by the common law the right of choosing churchwardens is in the parson and the parishioners. This is however by no means universally the case, as a custom prevails in many parishes for the parishioners to choose both, and in some both are elected by a select vestry. The eighty-ninth canon of 1603 directs that 'churchwardens shall be chosen yearly in Easter week by the joint consent of the minister and parishioners, if it may be; but if they cannot agree, the minister shall choose one and the parishioners another.' It has however been questioned how far these canons are binding upon the laity, even in matters ecclesiastical.

The usual duties of churchwardens are, to take care that the churches are sufficiently repaired; to distribute seats among the parishioners, under the control of the ordinary; to maintain order and decorum in the church during the time of divine service; and to provide the furniture for the church, the bread and wine for the sacrament, and the books directed by law to be used by the minister in conducting public worship. In addition to these ordinary duties, the churchwardens are by virtue of their office overseers of the poor, under the statutes for the relief of the poor; they are also required to present to the bishop all things presentable by the ecclesiastical laws, which relate to the church, minister, or parishioners. In large parishes there are sometimes officers called sidesmen (*synodsmen*) or questmen, whose business it is to assist the churchwardens in inquiring into offences and making presentments. Churchwardens and sidesmen were formerly required to take an oath of office before entering upon their respective duties; but by a recent statute, 5 and 6 Will. IV., c. 62, s. 9, it is enacted that, in lieu of such oath, they shall make and subscribe a declaration before the ordinary, that they will faithfully and diligently perform the duties of their offices.

If churchwardens are guilty of any wilful malversation, or if they refuse to account to the parishioners at the termination of their period of service, they may be proceeded against summarily before the bishop by any parishioner who is interested, or the new churchwardens may maintain an action of account against them at common law; in which action the parishioners, other than such as receive alms, are admissible as witnesses. (Stat. 3 Will. III., c. 11, sec. 12.) On the other hand, in all actions brought against them for any thing done by virtue of their office, if a verdict be given for them, or if the plaintiff be nonsuited or discontinue, they are entitled to double costs by Stats. 7 Jas. I. c. 5, and 21 Jas. I. c. 12.

Under the 59th Geo. III., c. 12, s. 17, churchwardens and overseers are empowered to take and hold lands in trust for the parish as a corporate body; and by a decision under this act, they can also take and hold any other lands and hereditaments belonging to the parish, the profits of which are applied in aid of the church rate. (Burn's *Justice*, and Burn's *Ecclesiastical Law*, tit. 'Churchwardens.')

CHUSITE. Found by Saussure in the porphyritic rocks near Limburg; occurs massive, granular, translucent and of a greasy lustre. Dr. Thomson refers it to Chrysolite.

CHUTA NAGPORE (LITTLE NAGPORE), a large zamindary in the district of Ramghur, forming the southern extremity of the province of Bahar, and containing, according to Major Rennell, 9329 square miles. The name Nagpore is indicative of the belief that the territory contains diamonds; and the distinctive title Chuta serves to distinguish it from the district of the same name in the Boonsla dominions. The surface of the country is much diversified. For the most part it is hilly and covered with jungle, the growth of which was, until very recently, much encouraged by the successive rajahs as the means of preventing invasion and preserving their independence, although it renders the climate unhealthy, especially to strangers. The country presents also several extensive plains, the soil of which is very fertile, and yields abundant harvests of pulse, wheat, barley, cotton, and sugar. The whole district is well watered, so far at least as relates to the irrigation of the land; the hills contain the sources of many streams, which do not attain any considerable size, so as to be navigable, until they have quitted the limits of the territory: under these circumstances, rice is produced in great abundance. Iron ore abounds in many parts of the district, but the expense of smelting would be so great that it is more advantageous to import iron from England than to establish furnaces upon the spot.

The country is but thinly populated in general, and contains only a small number of villages. Among the hills are some tribes who use little or no clothing, and are considered by the Brahmins as barbarians. For a long time subsequent to the first possession of Bahar by the English, the rajahs of Chuta Nagpore assumed and exercised independent powers, and did not allow of the jurisdiction of the English courts of justice. In 1809 a military force was sent into the country in order to establish the power of the British, and to organize a systematic police, which ends were accomplished with some difficulty. Previously to that time the rajah had paid to the government no more than 13,000 rupees per annum out of a clear revenue of 160,000 rupees, the residue being employed in keeping on foot a numerous body of soldiers. It has always been the system of the rajah to hold no personal communication with Europeans, and not to admit them into his presence. On the occasion just mentioned, the rajah, Govindnauth Sahi Deo, quitted his usual place of residence, and retreated into the jungle, where he succeeded in concealing himself, although brought to consent to the measures dictated by the English commander. Our present knowledge of the geography of the district and of its internal condition is very imperfect.

(Rennell's *Memoir*; *Report of Committee of Commons on the Affairs of India*, 1832.)

CHYDO'RUS (Zoology), Leach's name for a genus of *Branchiopoda* of the section *Lophyropa*. [BRANCHIOPODA.]

CHYLE (χυλός), the product of digestion formed by the action of the pancreatic juice and the bile on the chyme in the duodenum. [CHYME and DIGESTION.]

CHYME (χυμός), the product of digestion formed by the action of the stomach on the food. [DIGESTION.]

CIBBER, CAIUS GABRIEL, a celebrated sculptor, was a native of Holstein, and came to England during the Protectorate of Oliver Cromwell. The two figures of Raging and Melancholy Madness, which adorned the principal gate of Old Bethlehem Hospital, were his work, and also the bassi-rilievi on the pedestal of the London Monument. He married the daughter of William Colley, Esq. of Glaiston, in Rutlandshire, and granddaughter of Sir Anthony Colley, a stanch royalist, who in the cause of Charles I. reduced his estate from 3000*l*. to 300*l*. per annum. By this lady he had Colley Cibber, the actor, dramatist, and poet laureat. Mr. Cibber was employed in the latter years of his life by the earl, afterwards duke of Devonshire, in the improvement and decoration of the magnificent family seat at Chatsworth; and at the time of the Revolution in 1688, he took arms under that nobleman in favour of the prince of Orange.

CIBBER, COLLEY, was born, according to his own statement, on the 6th of November, o.s., 1671, in Southampton Street, Covent Garden. In 1682 he was sent to the Free School at Grantham, Lincolnshire. In 1687 he returned to London, and in 1688 was at his father's request received as a volunteer in the forces raised by the earl of Devonshire in support of the prince of Orange. In 1689 he indulged an early conceived inclination for the stage, by fixing upon it seriously as his profession; and after performing gratuitously for about eight or nine months, obtained an engagement at a salary of ten shillings per week. This pittance was afterwards increased to fifteen shillings; but a feeble voice and a meagre person were considerable obstacles to his progress, and the trifling part of the Chaplain in Otway's 'Orphan' was the first in which he obtained any notice. His performance of Lord Touchwood at a very short notice, in consequence of Mr. Kynaston's illness, obtained him the commendations of Congreve and five additional shillings per week. At this time, being scarcely twenty-two years of age, after a very short courtship, he married Miss Shore, to the great anger of her father, who immediately spent the greatest part of his property in the erection of a little retreat upon the Thames, which he called Shore's Folly. Mr. Cibber's professional progress was very slow for some years, notwithstanding his having turned author, and the success of his comedies, 'Love's Last Shift,' 'Love makes a Man,' 'She Would and She Would Not,' 'The Careless Husband,' &c. In 1711 however he became joint patentee with Collier, Wilks, and Dogget, in the management of Drury Lane, and afterwards with Booth, Wilks, and Sir Richard Steele; which latter partnership continued till the death of Mr. Eusden, the poet laureat, in 1730, when Cibber was appointed to succeed him, and sold out, having become during his nineteen years' management so great a favourite with the public in the performance of fops and feeble old men, that after he had retired from the stage he was occasionally tempted back to it by the offer of fifty guineas for one night's performance. In 1745 he played Pandulph in his own tragedy of 'Papal Tyranny,' being at that time in the seventy-fifth year of his age. On the 12th of December, 1757, about nine in the morning, he was found dead in his bed by his man-servant, with whom he had been in conversation about three hours before apparently in perfect health. He had recently completed his eighty-sixth year.

Mr. Cibber has described himself with considerable candour in his well-known and very amusing 'Apology' for his life. Vain, inconsistent, and negligent, he was withal a quick-witted, good-humoured, and elegant gentleman. His person, though spare and unprepossessing in youth, improved considerably as he advanced in life: a fact confirmed by a fine portrait of him in the collection at the Garrick Club, in his favourite part of Lord Foppington. As a writer of comedy, he is inferior perhaps only to Congreve, Wycherly, and Vanbrugh; but his Birth-day Odes are by no means exceptions to the usual dulness of such compositions. His best comedy is allowed to be 'The Careless Husband,' the dialogue of which is delightfully easy and polished; but the play which brought him the most money was his adaptation of Molière's 'Tartuffe,' entitled 'The Nonjuror,' on which Bickerstaff afterwards founded his 'Hypocrite.' For this play King George I., to whom it was dedicated, sent him 200*l*. He was the author and adapter of nearly thirty dramas of various descriptions, amongst which, besides those already mentioned, we may record 'The Provoked Husband,' written in conjunction with Sir John Vanbrugh, and the modern acting version of Shakspeare's 'Richard III.' His 'Apology' is published in two vols., 12mo., and his dramatic works in five vols., 12mo.

CIBBER, THEOPHILUS, the son of the laureat, was born on the 26th November, 1703. At the age of thirteen he was sent to Winchester school, where he remained but three or four years, for in 1721 we find him on the stage performing in the 'Conscious Lovers.' He acquired considerable reputation in characters similar to those supported by his father. He married early an actress of the name of Johnson, who died in 1733, and in 1734 he formed a second union with Miss Arne. His extravagant habits forced him to retire to France in 1738, and on his return he separated from his wife under very discreditable circumstances. After twenty years more passed some in prison and the rest in alternate prodigality and penury, he engaged with Mr. Sheridan of the Dublin theatre, and sailed for Ireland in company with Mr. Maddox, a dancer on the wire, in the month of October, 1758. The vessel was however driven by a storm on the coast of Scotland, and going immediately to pieces, Cibber, his companion, and the greater number of the passengers perished.

Cibber wrote and altered a few unimportant dramas, and was concerned in a work entitled 'An Account of the Lives of the Poets of Great Britain and Ireland,' 5 vols., 12mo., which was published under his name only.

CIBBER, SUSANNA MARIA, the daughter of Mr. Arne, an upholsterer in Covent Garden, and sister of Dr. Thomas Arne the composer, made her first appearance as a singer. In 1734 she married Mr. Theophilus Cibber, son of the laureat, and in 1736 attempted the part of Zara in Hill's tragedy of that name. Her success was most decided, and she rapidly became a great and deserved favourite. Her union with Mr. Cibber was an unfortunate one, and a separation took place about five years afterwards. She died January 30, 1766, and was buried in the cloisters of Westminster Abbey. Garrick is reported to have exclaimed when he heard of her death, 'Then Tragedy expired with her!'

CICADA'RIÆ. [HOMOPTERA.]

CICADE'LLA (Latreille), CERCO'PIDÆ (Leach), a family of insects of the order Hymenoptera and section Cicadariæ. This family is synonymous with the Cicada Ranatra of Linnæus. The species may be distinguished from those of allied groups by their having the antennæ situated between the eyes. These insects are generally small, and leap by means of their hind legs.

The genera may be arranged under two heads or sections; those in which the head is hidden by the pro-thorax, which is always very large, generally much humped, and has the posterior portion produced over the abdomen, sometimes so as to completely cover that part, or even extend beyond its apex; the antennæ are very small, and inserted in a cavity on the head. To this section belong the genera *Membracis*, *Tragopa*, *Darnis*, *Bocydium*, and *Centrotus*.

There are perhaps no insects more remarkable in structure, and whose appearance is more grotesque, than most of the species of this group. Their peculiarity arises from the great development of the pro-thorax: this part is sometimes so large as greatly to exceed in size all the other parts taken together. We have selected for illustration two species of the genus *Bocydium*, as being the most remarkable; the first is the *Bocydium tintinnabuliferum*. In this species the thorax is black and glossy; the posterior part is elongated and pointed, and from the disc there arises a vertical appendage, the summit of which bears four slender horizontal stalks, each of which is furnished with a little round black spherical body: these little globes are covered with fine hairs; the abdomen is reddish, and the wings are variegated with the same colour.

The second is the *Bocydium galeritum*. This species, as well as the one just described, inhabits Brazil; the prothorax is of a dark reddish-brown colour; the posterior part is elongated; the disc is elevated into a process which is at first compressed, but at the summit becomes dilated into a broad angular mass, and throws out a flattened portion, which suddenly bends downwards towards the body, and then runs parallel with it. The wings are transparent, with the exception of the basal and apical portion of the upper ones. The principal distinguishing characters of the genus *Bocydium* consist in the elytra being wholly or partially exposed, *i. e.*, not covered by the pro-thorax; and the posterior prolongation of the pro-thorax narrowed and pointed.

Fig. 1.

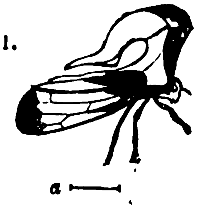

Fig. 2.

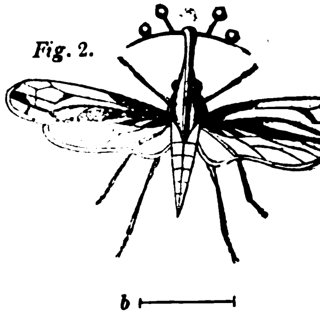

Fig. 1. Bocydium galeritum. *a*, natural length.
Fig. 2. Bocydium tintinnabuliferum. *b*, natural length.

Of the genus *Centrotus* two species are found in England; the more common species is *Centrotus cornutus*. This little insect is found on the leaves of the hazel and other shrubs, in the early summer months. It is about one-third of an inch in length, and of a brown colour; the pro-thorax is prolonged posteriorly (this part is compressed and pointed, and extends nearly to the apex of the abdomen), and the sides are dilated, and form two horn-like projections: a character from which the insect has received in France the name of *le petit Diable*. The wings are brownish and semi-transparent. In this genus the wings are exposed, as in the last, but the species differ in having a visible scutellum.

In the second division of the *Cicadellæ*, the head is on a line with the upper surface of the pro-thorax, or nearly so; the latter part is of moderate size, and without the extraordinary processes which characterize the former division—the wings are consequently always entirely exposed; the scutellum is distinct and of a triangular form. To this division belong the genera *Æetalion*, *Ledra*, *Ciccus*, *Cercopis*, *Eulopa*, *Euplex*, *Penthimia*, *Jassus*, *Tettigonia*, and some others.

Of the genus *Cercopis* (Latreille) we have many species in this country. They are all small. The largest and most beautiful of the British species is the *Cercopis vulnerata*. This insect is about one-third of an inch in length; black; the upper wings are obscure, and have each two large red spots (one at the base and another in the middle), and a fascia of the same colour near the apex, the black and the red being about equally divided; the under wings are transparent. This species is not uncommon in various parts of the country, and is found on the herbage in woods. *Cercopis spumaria* is one of the most common insects we have, being found in abundance on the various plants in our gardens. It is sometimes called the froghopper, from its habit of leaping when approached. Its colour is brown, the under wings are transparent, the upper wings have two white spots, one in the middle and another towards the apex. The larva, in form, resembles the perfect insect, except that it is destitute of wings; it is soft and of a greenish colour, and is always found on the leaves of plants inclosed in a frothy liquid, with which it surrounds itself, probably as a protection against the sun's rays. This frothy liquid is commonly known in England by the name of cuckoo-spit, and in France it is called *crachat de grenouille*. The pupa differs only from the larva in having rudimentary wings; the perfect insect is about three-sixteenths of an inch in length.

The characters of the genus *Cercopis* are:—Antennæ with the third joint conical, and terminated by an inarticulate seta; head furnished with ocelli. This genus was established by Fabricius, and has lately been subdivided. The insect last described belongs to one of these subgenera (*Aphrophora* of Germar), in which the head has the posterior margin concave, and the ocelli are more widely separated than in the genus *Cercopis* as now restricted. The characters of some other sub-genera will be found in a paper by Mr. Lewis, in the first part of the *Transactions of the Entomological Society*.

The genus *Ciccus* differs from *Cercopis* principally in the species having the seta of the antennæ articulated and composed of five joints; the anterior part of the head usually projects.

CICE'R, a genus of leguminous or fabaceous plants, allied to the vetch. A five-lobed calyx which projects on the upper side, and an inflated two-seeded pod with tuberculated seeds, give its character. One species, *Cicer arietinum*, the Chick pea, a native of Egypt and the Levant, is cultivated in the south of France for its seeds, which bear a striking resemblance to a ram's head. They have for ages been a common food in the eastern parts of the world, but their taste is unpleasant to Europeans. It is an annual, and bears pale violet solitary flowers. Two or three other species are known to botanists.

The most remarkable circumstance about *Cicer arietinum* is, that during the heats of summer its leaves and stem exude little viscid drops, which, on evaporation, leave behind crystals, nearly pure, of oxalic acid. Its grateful refrigerating qualities are owing to this acid. Persons who walk through the fields where it grows, with common leather shoes, find them destroyed by the acid. Those who are predisposed to calculous complaints should avoid its excessive use, either as a salad or boiled. The frequent use of this vegetable, or any other abounding with oxalic acid, leads to the formation of the oxalate of lime, or mulberry calculus, in the bladder, which is the most painful, and the least influenced by internal treatment. (See Majendie *on Gravel*, 2nd French edit.)

CI'CERO, MARCUS TULLIUS, was born at Arpinum on the 3rd of January, 106 B.C., in the consulship of Q. Servilius Cæpio and C. Atilius Serranus, and was thus a few months older than Pompey, who was born on the last day of September in the same year. [ARPINUM.] The family seat was on the south bank of the little stream Fibrenus (fiume della posta), near its junction with the Liris (Garigliano), where the stream of the Fibrenus dividing, forms an island and cascade, the scenery of which is the subject of the dialogue at the beginning of the second book 'De Legibus.' The villa Ciceronis is now occupied as a Dominican convent.

The grandfather of Cicero was living here at the time of his birth, and appears to have been a man of influence at Arpinum, where, on a petty scale, the political disputes formed a counterpart to those at Rome. The old man seems to have entertained the same views of public polity as his son, and vehemently opposed the introduction of the vote by ballot into the municipal proceedings at Arpinum, when a law to that effect was proposed by one Gratidius, whose family was intimately connected with the Marii, and whose sister, it may be observed, was the wife of old Cicero, and consequently the grandmother of the orator. The matter in dispute was referred to the consul Scaurus at Rome, who expressed his regret that a man of old Cicero's energy should have preferred to exert his talents in a petty corporation rather than on the great theatre at Rome. There is likewise a characteristic saying of his recorded by his grandson, that the men of his day were like Syrian slaves,—the more Greek they knew the greater knaves they were,—an observation probably aimed at his opponent Gratidius, who was well acquainted with that language. This Marcus Cicero had two sons, Marcus and Lucius. The younger of these, together with his uncle Gratidius, who was killed there, served under Antony the orator in his government of Cilicia. Lucius left a son of the same name, to whom his cousin Cicero was much attached, and whose death he deplores in one of his earliest letters to Atticus.

Marcus Cicero, the father of the orator, though he was on intimate terms with the leading men of the times, was compelled, by the delicacy of his health, to live in retirement; but this enabled him to pay the more attention to the education of his two sons Marcus and Quintus. His wife Helvia had a brother, Aculeo, the intimate friend of L. Crassus, a man equally distinguished for his oratory and the public offices he had held; and the two sons of Aculeo, with their cousins the young Ciceros, received their education together under teachers selected by Crassus. It is to this circumstance probably that we must attribute the special direction of Cicero's talents to the study of oratory. He was afterwards removed by his father to Rome, where he had the assistance of Greek instructors, more particularly the poet Archias, who was living under the roof of L. Lucullus. As soon as he had exchanged the boy's dress for the toga, he was placed under the care of Q. Mucius Scævola, the augur, and father-in-law of his father's friend Crassus, and upon his death attached himself to the pontifex of the same name, who excelled all his contemporaries in his knowledge of law, and added to his other accomplishments considerable powers of eloquence. While Cicero was thus preparing himself for the forum, he relieved the severity of his legal and philosophical studies by an intermixture of poetry. Even as a boy he had composed a poem called 'Pontius Glaucus,' which was extant in Plutarch's time, and he now translated the 'Phænomena' of Aratus into Latin verse, besides writing two original poems, one called 'Marius,' in honour of his fellow-townsman, which received the commendation of Scævola, and another entitled 'Limon.' But he was now arrived (B.C. 89) at the age when he was called by the laws of his country to the military profession, and he served his first campaign in the Marsic war under Pompeius Strabo, the father of the great Pompey, and was present when Sulla captured the Samnite camp before Nola. The termination of the Marsic war in the following year gave Cicero an opportunity of attending the lectures of two distinguished Greek philosophers; first Philo, who then presided over the Academy, and soon after Apollonius Molo of Rhodes, who had been driven from their homes by the arms of Mithridates. This prince had been long watching for an opportunity of attacking the authority of Rome. The late civil war in Italy had induced him to throw off all disguise. He had overrun the Roman province of Asia, and was already master of nearly all Greece, when the Romans concluded the war with their Italian allies, with the intention of opposing their formidable enemy in the East. But unhappily that which should have led to a union of their strength was the cause of divisions still more disastrous. The command of the war against Mithridates was disputed between old Marius and Sulla, and led to a series of civil commotions. Sulla however, who was at the time consul, had the important province of that war allotted to him. The appointment excited the furious opposition of the Marian party, and Sulla was unable to maintain the superiority of his party at Rome but by bloodshed and proscription. His departure for the Mithridatic war was the signal for re-action, and Marius re-entered Rome (B.C. 87) with the support of the consul Cinna, and put to death all the most distinguished leaders of the aristocratic party, who were unable to make their escape to Sulla's army in Attica Cicero's schoolfellow Pomponius was probably one of the fugitives, for he left Rome about this period, and by a twenty years' residence in Athens acquired the surname of Atticus. Of Cicero's pursuits during the three or four next years little more is known than that he wrote some rhetorical works, which dissatisfied his maturer judgment; probably the work entitled 'De Inventione,' besides translating the 'Œconomics' of Xenophon, and several dialogues of Plato. He was also in the habit of declaiming both in Greek and Latin, and received instruction in philosophy and logic from the stoic Diodotus, whom we find afterwards living under his roof, where in fact he died, leaving his property to Cicero. He had also a second opportunity of hearing Molo at Rome, when the philosopher was sent on an embassy to remind the senate of the services of his countrymen in the late war against Mithridates. In his twenty-sixth year (B.C. 81), when Sulla had extinguished all the democratic elements of the Roman constitution, Cicero made his first appearance as an advocate. The speech in favour of Quinctius, though not the first he delivered, is the earliest of those which are now extant. In the following year his voice was first heard in the forum in defence of Sextus Roscius of Ameria, on a charge of parricide. The subject matter of the trial was intimately mixed up with the late civil dissensions, so that it attracted much public attention. Cicero fully prepared himself for the occasion, and produced so powerful an impression, that, to use his own words, the public voice at once placed him among the first orators of Rome. When he had spent two years in the severe duties of his profession, the delicacy of his health led him to withdraw for a time from Rome. He first visited Athens (B.C. 79), where he devoted six months to Antiochus of Ascalon, the most distinguished philosopher of the old Academy. He also attended Phædrus and Zeno of the Epicurean school, in company with his friend Atticus, and practised declamation under the directions of an able rhetorician, named Diogenes, of Syria. He next traversed the whole Roman province of Asia, still cultivating his favourite pursuit of oratory under the first teachers of that country; and then crossed over into Rhodes, where, for the third time, he placed himself under Molo, and derived considerable benefit from his instruction, in correcting the redundancy of his style, and moderating the vehemence of his voice and action. He studied philosophy likewise under Posidonius.

In the year B.C. 77, after a two years' absence, during which Sulla had died, Cicero returned to Rome, and married Terentia, whose rank and station in society we may estimate by the fact that her sister Fabia was one of the vestal virgins. He applied himself again with zeal to the law courts and the forum, in which at this time the most distinguished orators were Aurelius Cotta and Hortensius; but next to them stood Cicero, whose services were in constant demand for causes of the highest importance. But independently of the reputation he was acquiring, he was at the same time opening the way to the political honours of his country; and it is a somewhat singular coincidence, that in the year B.C. 76 the three first orators of Rome, Cotta, Hortensius, and Cicero, were successful candidates for the several offices of consul, ædile, and quæstor, which they respectively filled in the following year. The provinces of the quæstors being distributed to them by lot, the island of Sicily fell to Cicero's share, or rather the western portion of that island, which had Lilybæum for its chief town; the whole island being under the government of S. Peducæus as prætor, with whom Cicero, and above all Atticus, lived on terms of the closest intimacy, until Peducæus fell with Pansa at the battle before Mutina. Sicily was one of the granaries, as it were, of Rome, and the quæstor's chief employment in it was to supply corn for the use of the city; and as there happened to be a peculiar scarcity this year at Rome, it was necessary to the public quiet to send large and speedy supplies. This task Cicero accomplished, he tells us, and at the same time gave the highest satisfaction to all parties in the province. In the hours of leisure he employed himself, as at Rome, in his rhetorical studies; so that on his return from Sicily his abilities as an orator were, according to his own judgment, in their full perfection and maturity. Before he left Sicily he made a tour of the island, and gratified himself by a visit to Syracuse, where he discovered the tomb of Archimedes, which had been lost sight of by his countrymen, and was found overgrown with briers. He came away from the island extremely pleased with the success of his administration, and flattering himself that all Rome was celebrating his praise. In this imagination he landed at Puteoli, and was not a little mortified on being asked by the first friend he met, 'How long he had left Rome, and what news he brought from thence?' This mortification however led him to reflect that the people of Rome had dull ears, but quick eyes; so that from this moment he resolved to stick close to the forum, and to live perpetually in the view of his countrymen.

Pompey was at this time carrying on the war against Sertorius in Spain. Nicomedes, king of Bithynia, soon after died, leaving the strange legacy of his kingdom to the Romans; and the king of Pontus, ever ready to avail himself of the dissensions of the Romans, and justified on the present occasion by the Bithynian intrigue, renewed his hostilities by a double invasion of Bithynia and Asia. The two consuls, Lucullus and Cotta, were both sent to oppose him; and while the arms of Rome were thus employed in the different extremities of the empire, a still more alarming war (B.C. 73) broke out at home, which originating with some gladiators led to an extensive insurrection of the slaves, and under the able conduct of Spartacus threatened the very existence of the state. During this turbulent period Cicero persevered in a close attendance upon the forum, though none of the speeches which he then delivered have been preserved, excepting those which relate to the prosecution against Verres. Peducæus had been succeeded, after one year's government of Sicily, by Sacerdos, and he, after the same interval, by Verres; for it was a principle of Roman policy to give to as many as possible a share in the plunder of the provinces; though occasionally superior influence, not the merit of the individual, led to a continuance of his government for two or even three years. Such was the case with Verres, who during three years made the Sicilians feel all those evils in their worst form which the Roman principles of provincial administration in bad hands were so well calculated to produce. Cicero had many difficulties to overcome in his endeavours to subject the criminal to the punishment of his crimes. In the first place the judices (jury), under the law of Sulla, would consist exclusively of senators; that is, of those who had a direct interest in protecting provincial mal-administration. Moreover at the very outset there started up a rival in one Cæcilius, who had been quæstor under Verres, and claimed a preference to Cicero in the task of impeaching him. A previous suit, technically called a *divinatio*, was necessary to decide between the rival prosecutors. Cicero succeeded in convincing the jury that his opponent's object was, to use another technical term, *prevaricatio*; that is, to screen the criminal by a sham prosecution. This previous point being settled in his favour, he made a voyage to Sicily to examine witnesses and collect facts to support the indictment, taking his cousin Lucius Cicero to assist him. Fifty days were spent in their progress through the island, in which he had to encounter the opposition of the new prætor Metellus, who was endeavouring, with many of the leading men at home, to defeat the prosecution. On his return to Rome he found it necessary to guard against all the arts of delay which interest or money could procure for the purpose of postponing the trial to the next year, when Hortensius and Metellus were to be consuls, and Metellus's brother one of the prætors, in which character he might have presided as judge on the trial. Cicero was induced therefore to waive the privilege of employing twenty days in the accusation; and a single speech on the 5th of August, followed by an examination of his witnesses and the production of documentary evidence, produced an impression so unfavourable to Verres, that even his advocate Hortensius was abashed, and Verres went forthwith into exile.

The five other speeches against Verres, in which Cicero enters into the details of his charges, were never actually spoken, if we may believe the commentator upon these orations—who passes under the name of Asconius—but were written subsequently at his leisure; partly perhaps to substantiate his charges before the public, but still more as specimens of what he could do in the character of an accuser, which he did not often sustain.

Though a verdict was given against Verres by the jury of senators, yet the past misconduct of that order in their judicial capacity had been so glaring that the public indignation called for the election of censors, whose office had slept for some years; and the magistrates so appointed erased from the roll of the senate sixty-four of that body, expressly on the ground of judicial corruption. To remedy the evil for the future a new law was passed, at the suggestion of the prætor Aurelius Cotta, hence called the *lex Aurelia*, by which the equites (knights) and certain of the commoners (*tribuni ærarii*) were associated with the senators in the constitution of public juries. It was subsequent to the enactment of this law that Cicero made the speeches in defence of Q. Roscius, M. Fonteius, and A. Cæcina. The first of these was the celebrated actor, whose name has since become proverbial. The suit grew out of a compensation which had been made for the death of a slave, whom Roscius had educated in his own profession. M. Fonteius was the object of a prosecution for extortion and peculation (*de repetundis*) in the province of Gallia Transalpina; and must have been guilty, if we may judge from the fragments of his advocate's speech which have come down to us. The cause of Cæcina was of a private nature, and turned entirely upon dry points of law. The ædileship of Cicero (B.C. 69) had little of that magnificence which was so commonly displayed in this office, but it gave the Sicilians an opportunity of showing their gratitude to the prosecutor of Verres, by supplies for the public festivals. After an interval of two years Cicero entered upon the office of prætor (B.C. 66), and it fell opportunely to his lot to preside in the court of extortion; a court especially provided against that ordinary offence in the administration of the provinces. The year of Cicero's prætorship was marked by the conviction of Licinius Macer, in opposition to the influence of his kinsman Crassus. But the most remarkable event in his prætorship was the passing of the Manilian law, by which the command of the war against Mithridates was transferred to Pompey, whose claims Cicero supported in a speech which still remains. It was in this year too that he defended Cluentius. This speech likewise exists, and gives a sad spectacle of the uncertainty of life and property at this period. Before the close of his prætorship he betrothed his daughter Tullia, who could not have been more than ten years old, to C. Piso Frugi. She was at present his only child, for his son Marcus was not born until the middle of the following year, which was also the birth-year of Horace.

On the expiration of his office he declined the government of a province, which was the usual reward of that magistracy, preferring to employ his best efforts at home towards the attainment at the proper period of the consular office. This was perhaps his chief object in undertaking the defence of C. Cornelius, the tribune of the preceding year, against a charge of treason, which was supported by the whole influence of the aristocracy. The guilt of Cornelius consisted in his energetic and successful support of the law against bribery in elections, called the *Lex Acilia-Calpurnia.* Cicero published two orations spoken in this cause, the loss of which is the more to be regretted, as they were reckoned among the most finished of his compositions, both by others and by himself. The return of Atticus from Athens at this time was most opportune to his friend Cicero, who looked upon the following year (B.C. 64) as the most critical in his life; and Atticus being intimately connected with the influential men of the aristocratic party, could give essential assistance to a new man, as the phrase was, against six candidates, two of whom were of patrician blood, while the fathers or ancestors of all had already filled public magistracies. Cicero's father just lived to witness the election of his son to the highest office in the state.

From this point the life of Cicero is the history of the times. Of the orations he made in the year of his consulate he has himself given a list in a letter to Atticus.

On the kalends of January, immediately upon his assuming the consular robes, he attacked a tribune, P. Servilius Rullus, who had a few days before given notice of an Agrarian law, the meaning of which term has already been explained under that name. Of this speech, which was addressed to the Senate, there exists a considerable fragment, and enough to show that Cicero was already prepared to attach himself to the aristocratic party, whereas up to this time his political life had been of an opposite complexion. His panegyrist, Middleton, seems to acknowledge the change, and attributes his past conduct to that necessity by which the candidates for office were forced, in the subordinate magistracies, to practise all the arts of popularity, and to look forward to the consulship as the end of this subjection. Before the people indeed, to whom he addressed two speeches upon the same subject, Cicero still wore the popular mask; and while he expressed his approbation of the principle of Agrarian laws, and pronounced a panegyric on the two Gracchi, he artfully opposed the particular law in question on the ground that the bill of Rullus created commissioners with despotic powers that might endanger the liberties of Rome, and he prevailed on one of the other tribunes to put his veto upon the bill. In the defence of Rabirius, who was charged with the murder of the tribune Saturninus three-and-thirty years before, he goes so far as to maintain the right of the senate to place Rome in a state of siege, if we may borrow a modern term, or, in other words, to suspend all the laws which protect the lives of citizens, yet, in the same speech, he endeavours to curry favour with the people by heaping the highest praises on their favourite Marius. Rabirius had already been convicted by the judges appointed to investigate the charge; but appealed, as the law allowed him, to the people, who accordingly assembled in the Field of Mars to hear the appeal. While the trial was proceeding, it was observed that the flag upon the Janiculum on the other side of the Tiber was lowered. This of necessity broke up the assembly, according to an old law which was made when the limits of the Roman empire extended only a few miles from the city, and was intended to protect the citizens from being surprised by the enemy. The object of the law had long passed away, but Roman superstition still maintained the useless ceremony, and the aristocratic party employed it on the present occasion in the hands of Metellus the prætor to annul the proceedings of justice. The orations in which he defended Otho against the populace, who were enraged at his law for setting apart special seats in the theatre for the order of the knights, and that in which he opposed the restoration of their civil rights to the sons of those who had been proscribed by Sulla, were also delivered this year, but nothing remains of them. Of the conspiracy against Catiline, and the several speeches which were made by Cicero in relation to him, it is unnecessary to say more than will be found under the head CATILINA.

Two other causes, in which Cicero's services as an advocate were called forth during this year, were those in which he defended C. Calpurnius Piso, the consul of 67 B.C., and L. Murena, the consul elect. The oration in defence of Piso is not extant, but it appears that the prosecution was for extortion in his government of Cisalpine Gaul, and was maintained at the instance of Cæsar. Cicero, in a speech made on a subsequent occasion, seems to admit the guilt of his client, and to account for his acquittal on grounds altogether foreign to the merits of the case; another proof of the change that had taken place in the patriotic prosecutor of Verres. His conduct is not less reprehensible in the affair of Murena, who was charged with bribery, treating, and other violations of the law, in his late election to the consulship. His guilt will not be doubtful to a careful reader of his advocate's speech. The prosecution was supported by Sulpicius and Cato, the former a man who may be looked upon as almost the founder of Roman law as a science, and Cato certainly the most honest of his party. Yet Cicero, instead of grappling with the charge, descends to a personal attack on the advocates opposed to him, rallying the profession of Sulpicius as trifling, and the principles of Cato as impracticable. His defence amounts in fact to a defence of the crime rather than the criminal, which was the more discreditable, as he himself had only a few weeks before carried a new law against bribery.

The success of Cicero, in crushing the Catilinarian conspiracy, would probably have earned for him the unmixed good will of the aristocratic party, had he not offended them by the vanity and presumption which that success engendered, and which were the more offensive to them in one whose origin they despised. So completely was he carried away by his sense of his services to his country that he wrote a history of his consulship in Greek, and even sung his own glories in verse; but the most decisive evidence of his unbounded vanity is the extraordinary letter which he addressed to his friend Lucceius. (*Ad Fam.* v. 13.)

On the other side he had damaged his reputation with the people by his evident change of principles; and the precipitate execution of the conspirators, without the form of a trial, was an offence against the laws of the country which the sanction of the senate could not justify. Already on his laying down his office there were symptoms of that hostility which gradually increased, and in a few years drove him in disgrace from the city which he had lately saved.

But we must return for a while to his forensic exertions. While the associates in the crimes of Catiline were, for the most part, prosecuted and driven into banishment, it pleased the party of the senate to screen P. Sulla, whose guilt is generally asserted by the historians of the times. Hortensius and Cicero were his advocates, and the support of the latter is reported to have been bought by a loan of money, which Cicero required for a purchase he was then making of a house on the Palatine Hill. To see this in its true light, it should be recollected that the receipt of a fee was at variance with the avowed principles of the Roman bar. The anecdote stands upon the authority of A. Gellius, which might have been insufficient, were it not indirectly yet decisively confirmed by more than one passage in Cicero's letters. In the following year Quintus Cicero, the brother of the orator, was appointed to the government of the rich province of Asia, as successor to L. Flaccus, who came home with the usual reputation for extortion, for which he was called to account two years after. This L. Flaccus had been the chief prætor in the consulship of Cicero, and in that capacity had been of great service in the detection of the conspiracy, so that he had a certain claim upon Cicero, which was not neglected. But this trial was preceded by one of the same nature which more nearly concerned the orator.* C. Antonius, who had been his colleague in the consulship, was recalled from the province of Macedonia, where he had presided for two years, and had to defend himself against an impeachment for the gross rapacity of which he had been guilty. This province had originally fallen to the lot of Cicero, who took credit on many occasions for his disinterestedness in transferring the lucrative appointment to his colleague. He omitted to state that there was a secret agreement between them, by which Antonius bound himself to make a pecuniary return to Cicero; and the extortion of which the proconsul had been guilty was in part owing to this obligation. The very day on which Antonius was condemned was marked by an event still more fatal to the peace of Cicero—the adoption of Clodius, his enemy, into a plebeian family. The object of this ceremony was to render Clodius eligible to the tribunate, from which, as a patrician, he was excluded; and no sooner was the obstacle removed than he offered himself as a candidate, and was elected without opposition. After some little manœuvring, the cause and object of which are not very intelligible, he made public advertisement of several new laws, which were all aimed at the authority of the senate; and among them was one to the effect that whoever took the life of a citizen uncondemned and without a trial should be interdicted from fire and water. Although Cicero was not named in this law, it was so evidently aimed at him, that it was necessary for him at once to decide upon the course he would pursue. Some recommended him to resist the law by force, but when he found that Pompey was unwilling to support him, he took the advice of his friends Cato and Hortensius, which coincided with the views of Atticus, and leaving the field to his adversaries, went into voluntary exile. Leaving Rome towards the end of March (B.C. 58), he proceeded to Vibo with the intention of crossing over into Sicily, but from this he was prohibited by the governor, Virgilius, although he was of the same political party, and was under obligations to Cicero. He received about the same time information from Rome that a special law had been passed, which forbade him to appear within a distance of four hundred miles. Under these circumstances he changed his route, and proceeded first to Brundisium, where he was hospitably entertained for some weeks, in defiance of the law. He then crossed over to Dyrrhachium, where he was received by Plancius, the quæstor of the province, and conducted by him to Thessalonica. The conduct of Cicero in his exile was such as might have been expected from one whose mind had been so extravagantly elated in prosperity. He gave himself up entirely to despondency; spoke of his best friends as enemies in disguise, not even sparing Atticus and Cato; and so completely lost the control of his feelings and his conduct, that his mind was supposed to be deranged. In the mean time, his friends at Rome, whose fidelity he doubted, were actively engaged in taking measures for his recall. Already on the 1st of June an unsuccessful motion was made in the senate to that effect. The election, too, of his friend Lentulus Spinther to the consulate, offered a brighter prospect for the ensuing year, but in the interval there occurred a little incident which gave him fresh uneasiness. Some of his enemies had published an oration, which he had composed some years before in an angry moment, against an eminent senator, and had shown privately to his intimate friends. Its appearance at so untoward a moment alarmed Cicero, who imagined it had been destroyed, and he wrote to Atticus requesting him to disavow it. 'Fortunately,' says he, 'I never had any public dispute with him, and as the speech is not written with my usual care, I think you may convince the world that it is a forgery.'

---

* We have omitted a mysterious affair which occurred this same year, B.C 59. The facts are these: One Vettius, only known to us before this as an

Towards the end of the year his residence at Thessalonica became disagreeable to him, and indeed he thought dangerous. His enemy Piso had been appointed governor of Macedonia, and the troops who were to serve under him were already expected. Even before this, some of the accomplices of Catiline, who were living in Macedonia as exiles, had been plotting, it was said, against the life of Cicero. He therefore found it safer to remove to Dyrrhachium, where he had friends, although it fell within the distance prohibited by the law. His residence upon this coast afforded an opportunity likewise for an interview with his friend Atticus, who was in the habit of visiting a favourite estate near Buthrotum. While Cicero was harassing himself with perpetual fears and suspicions, his cause was proceeding prosperously at Rome. The tribunate of Clodius terminated in December; the new tribunes were, almost without exception, friendly to his recall; and on the first day of the new year the new consul Lentulus moved the senate for his restoration. His opponents, however, were not yet driven from the field. The tribunitial veto was employed more than once to check the proceedings. Scenes of riot and bloodshed disgraced the streets of Rome. Yet at last, on the 25th of May, a decree in his favour passed the senate; and on the 4th of August a law, in confirmation of the decree, was carried by the people in the great meeting of the Centuries. Cicero, in anticipation of these measures, had embarked for Italy on the very day the decree of the senate was passed, and landed the next day at Brundisium, where he was received by his daughter Tullia. The inhabitants of the city were profuse in the honours they paid him, and when the news, that the law had passed the Centuries, summoned him to Rome, the inhabitants of the cities through which he passed flocked in crowds to congratulate him.

Cicero's return was, what he himself calls it, the beginning of a new life to him. He had been made to feel in what hands the weight of power lay, and how dangerous it was to lean on the support of his aristocratical friends. Pompey had served him on the late occasion of his recall from exile, and had acted with the concurrence of Cæsar, so that it was a point of gratitude as well as prudence to be more observant of them than he had hitherto been. To the former he took an early opportunity of showing his gratitude by proposing that he should be commissioned to provide for a better supply of corn at Rome, where the unusual price of bread had already occasioned serious disturbances. For this purpose he recommended that Pompey should be invested with absolute power over all the public stores and corn-rents of the empire for five years. The proposition was readily accepted, and a vote passed that a law to that effect should be brought before the people. This law was favourably received by all parties, and Pompey named the proposer of the law the first among his fifteen assistant commissioners, an appointment which the latter accepted, with the stipulation that he should not be called away from Rome. Meanwhile although Cicero was restored to his former dignity, there was a difficulty in the restitution of his property. The chief delay was about his house on the Palatine Hill, which Clodius had contrived to alienate, as he hoped, irretrievably, by demolishing the building and dedicating a temple upon the ground to the goddess Liberty. The senate therefore could only make a provisional decree, that if the college of priests discharged the ground from the claims of religion, the consuls should make a contract for rebuilding the house. The pontifical college was accordingly summoned to hear the cause on the last day of September, and Cicero personally addressed them in a speech which he himself considered one of his happiest efforts, and which he thought it a duty to place as a specimen of eloquence in the hands of the Roman youth. The speech, however, which now occupies a place among his works, under the title *Pro Domo sua apud Pontifices*, as well as those bearing the names of *De Haruspicum Responsis*, *post Reditum in Senatu*, and *Ad Quirites post Reditum*, all professing to have been delivered during this year, have been pronounced by the ablest critics to be spurious. The college gave a verdict in terms somewhat evasive; but the senate concluded the matter by a distinct vote in Cicero's favour; and the consuls immediately put the decree in execution by estimating the damage which had been done to Cicero's property. In this estimate his villas near Tusculum and Formiæ were included. But the estimation was far below what Cicero thought himself entitled to, and he attributed this injustice to the jealousy of the aristocracy, who, as they had formerly clipped his wings, so were now unwilling that they should grow again. Scarcely had the house upon the Palatine begun to rise, when a mob, instigated, according to Cicero, by Clodius, attacked the workmen, and afterwards set fire to the adjoining house, in which his brother Quintus lived. This riot was only one of many which at this time disgraced the city.

Milo, as well as Clodius, had his armed bands, and was avowedly seeking for an opportunity of murdering Clodius; while Cicero himself appears as a party in a forcible attack upon the Capitol for the purpose of destroying or carrying off the brazen tablets on which the law of his exile had been engraved. One of those who took an active part in the disturbances was P. Sextius, who, in his tribunate, had been instrumental in the restoration of Cicero. He was brought to trial for these disturbances the following year, when Cicero, in gratitude, undertook his defence, and obtained an acquittal; and, not satisfied with a mere verdict, he the next day made a furious attack in the senate upon a senator, Vatinius, who had been one of the chief witnesses against Sextius. Cicero was less fortunate in his defence of L. Calpurnius Bestia, who was prosecuted about the same time for bribery in the last election of prætors. In the same year he gratified his powerful friends Pompey and Cæsar by appearing as the advocate of L. Cornelius Balbus, a native of Gades, who had received the citizenship of Rome. The legality of his franchise was the subject-matter of the trial. It is somewhat strange to find Cicero so closely allied as he was at this time with Cæsar, on whom he had showered his abuse on nearly every occasion; but the fact and the disgrace of it are acknowledged by himself repeatedly in his letters to his friend Atticus. 'It is a bitter pill,' says he, 'and I have been long swallowing it, but farewell now to honour and patriotism.' There exist two other speeches delivered by him during the same year: one of these was in the senate, on the annual debate about the appointments to the provinces, and he employed the opportunity thus afforded in a furious attack on the private lives and public conduct of Piso and Gabinius, who had been the consuls at the time of his exile, and had assisted his enemy Clodius, and recommended their recall from the provinces they were then governing. He concluded his harangue by defending his alliance with Cæsar. The other speech just referred to was made in defence of Cælius, a man who by his open profligacy and unprincipled conduct was notorious even among his countrymen. He was charged with the crime of procuring the murder of an ambassador from Alexandria, and also of attempting to poison a sister of Clodius. Cælius was acquitted, and lived for many years on most intimate terms with Cicero; indeed the letters that passed between them constitute a whole book in his miscellaneous correspondence. On the return of Piso from his government of Macedonia, at the beginning of the following year, he complained of the attack which had been made upon him by Cicero in the debate about the provinces. Cicero replied to him in another invective, more violent than the former. One would hope that the speech purporting to have been spoken on this occasion was not genuine, for if it is, no one can read it without awarding to Cicero the prize among orators for coarseness and personality; and in fact he takes credit to himself, in his treatise on the perfect orator (*de Oratore*), for his invective powers.

In the spring of the following year he commenced the treatise on politics (*de Republicâ*), the loss of which the learned had long regretted, when Angelo Maio, in 1823, discovered a considerable portion of it in the Vatican library. The manuscript, which is of parchment, contained a treatise on the Psalms, in a small distinct character; but Maio perceived underneath traces of a larger type, in which he soon recognised the style of Cicero, and the matter, nay even the title, of the *de Republicâ*. But to return to the narrative, the greater part of the year 54 B.C. was employed by Cicero in his usual occupation of defending the accused. 'Not a day passes,' says he, in a letter to his brother, 'without my appearing in defence of some one.' Among others, he defended Messius, one of Cæsar's lieutenants, who was summoned from Gaul to take his trial; then Drusus, who was accused of prevarication, or undertaking a cause with the intention of betraying it; after that, Vatinius, the last year's prætor, and Æmilius Scaurus, one of the consular candidates at the time, who was accused of peculation in the province of Sardinia; about the same time likewise his old friend Cn. Plancius, who had received him so generously in his exile, and being now chosen ædile, was accused by a disappointed competitor of bribery and corruption. All these were, as usual, acquitted; but the orations are lost, excepting the one which he delivered in favour of Plancius, and a considerable fragment of that for Scaurus. This fragment is another of the discoveries of Maio, who found it in the year 1814, with some other fragments of Cicero's orations, in the Ambrosian library at Milan. As was the case with the 'De Republicâ' the text of Cicero had been obliterated as much as possible from the parchment to make room for the Latin poem of the Christian writer Sedulius. Cicero's undertaking the defence of Vatinius, who had been always intimately allied with Cæsar, and on that account had on more than one occasion been the object of Cicero's abuse, his personal deformity being a favourite topic of raillery with the orator, at once surprised and offended the aristocratic party. They did not conceal from him their disgust, and Cicero found it necessary to make what defence he could of his political tergiversation in a long and ably written letter to his friend Lentulus Spinther, who was then governor of Cilicia (*Ad Fam.* i., 9). The compliment of an epic poem addressed to Cæsar was another proof of the change in his political views; but a still more decisive piece of evidence is furnished by his conduct in relation to Gabinius, who returned at this time from his government of Syria, and was immediately overwhelmed with public prosecutions. Cicero had not forgotten that Gabinius, as one of the consuls at the time of his exile, had supported his enemy Clodius; and he had openly avowed his opinion of his crimes in Syria—crimes, too, which, if we may believe Cicero, included murder, peculation, and treason, in every form; but he was willing to sacrifice both his public and his private feelings at the intercession of Pompey. In the first trial he was called as a witness against Gabinius, but had the prudence to put his evidence in such a form as to give the highest satisfaction to the accused. In the second he became still bolder, and appeared as his advocate, but was unable to save him from conviction, fine, and banishment. The speech delivered by Cicero is not extant, and probably was never published. There is preserved however the speech made by him on the trial of C. Rabirius Postumus, which was an appendix to that of Gabinius. The whole estate of the latter had proved insufficient to answer the damages in which he had been cast; and the Roman law, in such a case, gave the right of following any money illegally obtained to the parties into whose hands it had passed. Rabirius had acted at Alexandria as the agent of Gabinius with Ptolemy, and in that capacity was said to have received part of the ten thousand talents which the king had paid the Roman general as the price of his services. As this trial followed closely upon the preceding, and was so intimately connected with it, the prosecutors could not spare the opportunity of rallying Cicero for the part which he had acted. In the end of the year Cicero consented to be one of Pompey's lieutenants in Spain, and was preparing to set out thither, when he was induced to abandon the appointment on perceiving from his brother's letters, who was at that time serving in Gallia, that such a step would probably give umbrage to Cæsar, for the recent death of Julia had already broken the chief link which held Cæsar and Pompey together. At the beginning of the following year, news was received of the death of Crassus and his son Publius, with the total defeat of his army by the Parthians. By the death of young Crassus a place became vacant in the college of augurs, for which Cicero declared himself a candidate, and being nominated by Pompey and Hortensius, was chosen with the unanimous approbation of the whole college. This appointment had been for some years the highest object of Cicero's ambition; and the addition to his dignity was of service to him at this time, as he was putting forth all his influence to further the election of his friend Milo to the consulate. The constant disturbances in the city prevented the comitia from being held until the year was closed, and in the middle of January the murder of Clodius by one of Milo's gladiators, in the presence, and at the command too, of his master, placed Milo in a different position. The fury of the people at the death of their favourite broke out in the most violent excesses, which were only aggravated by the endeavours of Milo's powerful friends to screen him from punishment. These disturbances were at last quieted by the appointment of Pompey to the consulship, who was armed too with extraordinary powers by the senate, and finally Milo was brought to trial, condemned in spite of Cicero's eloquence, and banished from Italy. Cicero is said to have been so alarmed on the occasion, by the presence of the military whom Pompey had stationed around the court to prevent any violence, that his usual powers failed him; and indeed the speech which is found among his works, under the title of the defence of Milo, is very far from being that which he actually delivered. In the two trials of Saufeius, one of Milo's confidants, which grew out of the same affair, Cicero was more successful; and he had soon after some amends for the loss of his friend in the condemnation of two of the tribunes, who had been their common enemies, for the part they had taken in the late commotions. One of these, T. Munatius Plancus, Cicero himself prosecuted, which is the only exception, besides that of Verres, to the principle which he laid down for himself of never acting the part of an accuser. It appears to have been soon after the death of Clodius that Cicero wrote his treatise 'On Laws' (de Legibus), three books of which are still preserved; but the work in its original form contained probably, like the 'De Republica,' to which it is a kind of supplement, as many as six books, for antient authors have quoted from the fourth and fifth. But the civil and literary pursuits of Cicero were soon interrupted by the demand for his services abroad. Among the different laws which Pompey brought forward for checking the violence and corruption which the candidates employed for the attainment of public office, was one which disqualified all future consuls and prætors from holding any province until five years after the expiration of their magistracies. But before the law passed, Pompey procured an exception for himself, getting the government of Spain and Africa continued to him for five years longer, while, to gratify Cæsar on the other side, Cicero, at the special request of Pompey, induced one of his friends to bring forward a law by which Cæsar's presence might be dispensed with in suing for the consulship in the following year. There was valid ground for this privilege being conferred upon Cæsar in the circumstances of the Gallic war, where the success of the Roman arms would have been seriously endangered by his absence. Thus Cicero and Pompey were the chief instruments in passing the very law which they afterwards declared unconstitutional and invalid, and so brought upon their country the horrors of civil war. As the magistrates of the time being were precluded from provincial government by Pompey's law, it was provided that for the next period of five years the senators of consular and prætorian rank, who had not held foreign command upon the expiration of their magistracies, should divide the vacant provinces by lot: in consequence of which, Cicero most reluctantly undertook the government of Cilicia, with which were united Pisidia, Pamphylia, Cyprus, and three dioceses, as they were called, of the adjoining province Asia. Thus Cicero found himself in the very position which it had ever been one of his chief objects to avoid, and his friends were the more uneasy as that quarter of the empire was threatened by the Parthians in revenge of the late invasion of their territories by Crassus. Under these circumstances Cicero was fortunate in having among his lieutenants two such men as his brother and Pontinius. The latter had established a high military reputation by his successes and triumph over the Allobroges, while the merits of Quintus Cicero as a soldier had been proved and acknowledgèd by Cæsar in Gallia.

Still the government of a province was suited neither to the taste nor the talents of Cicero, and he urged all his friends before his departure, as well as in nearly every letter he subsequently wrote, not to allow the command to be extended beyond the year which the law of Pompey required, or the year itself to be lengthened out by the caprice of the pontifical college; for the length of the Roman year at this time varied according as it was the pleasure of that body to insert more or less intercalary days in the month of February, and the Pontifices were guided in this not by any fixed rule, but by private motives, lengthening or shortening the year to favour a friend or injure an enemy.

Cicero left the city about the 1st of May, and on his arrival at Tarentum paid a visit to Pompey, with whom he had a conference on the serious aspect of affairs, and was assured by him that he was prepared for the dangers which threatened them. In the middle of June he proceeded from Brundisium to Corcyra and Actium, thence partly by land and partly by water to Athens, where he spent ten days, and then crossed in fifteen days to Ephesus, touching at several islands on the way. He had here a foretaste of the duties he would have to perform; for among the deputations which waited upon him at his landing was one from the citizens of Salamis in Cyprus, to lay before him their complaints against the extortion and cruelty of a Roman citizen named Scaptius, who had claimed from the city a large sum upon a bond, together with an accumulation of interest at the rate of forty-eight per cent.; and who had used the military authority he held under the late governor, Appius, to besiege the senate of Salamis in their council-room, until five had died of starvation. As Brutus had recommended the interests of Scaptius to Appius, who was his father-in-law, so he now laboured to place him in the same degree of favour with Cicero, and was seconded in this suit by the letters of Atticus; but the extortion raised Cicero's indignation, and he resisted the claims of Scaptius, though Brutus, in order to move him the more effectually, at last confessed what he had all along dissembled, that the debt was really his own, and Scaptius only his agent in it.

Cicero however was the friend of justice up to a certain point only, for when he refused the usurious interest, Scaptius in a private interview told him that though the principal was only one hundred and six talents, the Salaminians through some mistake believed it to be two hundred, and suggested that Cicero might safely give an award for the larger sum. Cicero himself gives us this anecdote in his letters to Atticus (v. 21), adding that he assented to the proposal, but was unable to effect the object because he found the Salaminians more precisely acquainted with the accounts than Scaptius had anticipated. This same Brutus, whose character is so commonly put forward as one of the finest examples of Roman virtue, had applied for the assistance of Cicero in another affair of a nature somewhat similar. The king of Cappadocia, whose empty coffers proved how dearly he paid for the protection of the Roman senate, owed him, he said, a very large sum of money. But Cicero was unable to render him the least assistance in the recovery of this money, as the king owed a much larger sum to Pompey, whose position in the political world at Rome gave him a higher claim, and yet was unable to pay him the full interest of the debt. These instances afford a good example of the miseries which resulted from the Roman form of provincial government. But Cilicia had felt these miseries in a degree more than usually severe under the late governor Appius, the traces of whose extortion were visible every where, and could only be compared, says Cicero, to the track of a wild beast. Indeed he found employment enough in healing the wounds which Appius had inflicted. Cicero appears not to have concealed his feelings upon this subject: at any rate the accounts which reached Appius led him to believe that Cicero was encouraging his enemies at Rome in their determination to bring him to public trial; nor could he believe the protestations of Cicero to the contrary, when he found his prosecutor Dolabella was about to be married to Cicero's daughter. He again expostulated, but Cicero replied to his complaints by disclaiming all knowledge of any such matrimonial negotiation, the falsehood of which is demonstrable from the letters which he wrote at the same period to Atticus. But Appius and Pompey were allied by the marriage of their children, and the latter induced Cicero to promise everything from the province that could be of service to the accused, so that the guilty governor was acquitted without difficulty. The military proceedings of Cicero were not of a very interesting nature. He had proceeded at once on his arrival in the province to the south-eastern frontier, which was threatened by the Parthians; but the Roman officer who commanded in the adjoining province of Syria had so completely occupied the attention of the enemy, that Cicero's troops never came in sight of them. Being unwilling however to let the army return into winter-quarters without effecting anything, he attacked some of the mountain tribes of Amanus, whose position had hitherto protected them, and took a number of prisoners; while his troops had a pretext for saluting him 'imperator.' He was also successful in the siege of a robber-fort called Pindenissus, for which his friends at Rome obtained him the honour of a public thanksgiving. His other services in Cilicia include nothing deserving especial notice, and he was happy when the year of his appointment expired, and enabled him to return to Italy. He landed at Brundisium towards the end of November, displaying his laurel-wreathed fasces, for his friends, and among them Pompey, flattered him with the notion that his eminent military services deserved nothing less than a triumph. But when he reached the neighbourhood of Rome on the 4th of January, he found matters of a more serious nature in agitation. The senate had just passed a decree that Cæsar should dismiss his army, and when M. Antony and another tribune opposed their veto to it, proceeded to that vote which gave the consuls and other magistrates a power above all the laws. The tribunes fled to the camp of Cæsar, who, considering this decree as equivalent to a declaration of war, advanced with a rapidity which destroyed all the arrangements of the senate. The consuls fled from Rome, accompanied in their flight by Cicero and the leading men of the aristocracy, in the hope of defending the southern part of the peninsula. With this view the principal senators had particular districts assigned to them, Cicero undertaking to guard the coast south of Formiæ and the country around Capua; but the rapid advance of Cæsar drove Cicero from his purpose. He disavowed the military engagement he had undertaken to fulfil; made different excuses for not joining Pompey in his march to Brundisium; and finally, when Cæsar made himself master of Corfinium, and by his magnanimous liberation of Lentulus Spinther, and other senators, gave the lie to those reports of his cruel intentions which his enemies industriously circulated, Cicero deemed it a favourable opportunity to open a negotiation with Cæsar, under the pretext of thanking him for his generosity to his friend Lentulus. In the middle of March Pompey sailed from Brundisium, abandoning Rome and Italy to his opponent. The return of Cæsar from Brundisium to the capital afforded an opportunity for an interview, in which it appears to have been stipulated that Cicero should remain in Italy, and observe a strict neutrality.

When Cæsar proceeded to Spain to oppose the Pompeian troops under Afranius, he left Antony in command of Italy, with especial directions to watch the movements of Cicero, who, residing upon the coast, occasionally showed symptoms of a disposition to slip off and join Pompey in Greece. This vacillation was not unobserved by Antony, and drew from him a monitory letter; but in vain. An account of some temporary success obtained by Afranius in Spain, magnified by himself and injudicious friends into a certain prospect of speedily destroying Cæsar and his army, led many of the wavering to fly from Italy to the camp in Greece. Cicero appears to have been one of these; at any rate he made his escape in the early part of June, and met with a cold welcome from the army of the senate. He was not present at the battle of Pharsalia, having stayed behind at Dyrrhachium, where he received the news of that decisive engagement, and, refusing to join those who determined to cross over into Africa with the intention of still maintaining the war, he again committed himself to the mercy of the conqueror, and landed at Brundisium at the end of October, B.C. 48. Here he passed many miserable months, the laurels upon his fasces drawing upon him an attention which he would gladly have avoided, while the news of Cæsar's difficulties in Egypt and the successes of the Pompeians in Africa again inclined the balance of the war. All this time he had received no intimation of pardon from Cæsar himself, though he was assured of his safety by Cæsar's friends. On the other hand, should the Pompeians ultimately succeed (and they were already talking confidently of coming over from Africa into Italy), he was sure to be treated as a deserter, for he well knew that while Cæsar pardoned even his enemies when they submitted to his power, it was a declared law on the other side to consider all as enemies who were not actually in their camp. After a long series of mortifications, he was cheered at last by a kind letter from Cæsar himself, and still more when Cæsar landed at Brundisium after his successful expeditions in the east, and gave him a reception which at once removed his fears and induced him to follow the conqueror to Rome. About the end of the year Cæsar embarked for Africa, and again the empire was in suspense; for the name of Scipio was thought ominous and invincible on that ground. Cicero, to relieve his mind, now shut himself up with his books, and entered into a close friendship with Varro, a friendship which was consecrated by the mutual dedication of their learned works to each other—of Cicero's 'Academic Questions' to Varro, of Varro's 'Treatise on the Latin Language' to Cicero. One of the fruits of this leisure was his dialogue on famous orators, called 'Brutus,' in which he gives a short character of the chief orators of Greece and Rome. But though the work was finished at this time, it was not made public till the year following after the death of his daughter Tullia.

He now parted with his wife Terentia, who had lived with him more than thirty years; and whatever may have been the causes or pretexts for this separation, he exposed his conduct to no little suspicion by marrying, almost immediately after, a young ward named Publilia, possessing much beauty and very considerable property, over which he had been placed as trustee by her father's will. Terentia subsequently married Sallust, the historian, and even after his death again entered into the married state once, if not twice. She is said to have lived to the age of 103. Amid these domestic troubles, Cicero perhaps found some consolation in the marked attention paid to him by Cæsar, who returned victorious from Africa in the summer of 46 B.C.; but any gratification he may have derived from this source must have been diminished by his consciousness of the offence he was giving to his former friends through his close intimacy with the dictator. The panegyric which he composed about this time in honour of Cato has indeed often been alleged as a proof of his being no temporizer; but if the treatise had come down to us, we should probably have found that Cicero had succeeded most happily in blending his eloge upon the conquered with a well-tempered flattery of the conqueror. That he possessed this happy and useful talent is apparent from the speech he delivered at this time in favour of Ligarius, and the defence of Marcellus might be put in evidence to the same effect, if there were not strong grounds for doubting the authenticity of the oration bearing that name. At the end of the year Cæsar was called away in great haste into Spain to oppose the sons of Pompey; and young Cicero requested his father's permission to go to Spain, that he might serve under Cæsar with his cousin Quintus, who was already gone thither. Cicero objected to his serving in arms against their former friends, and thought it more desirable that he should go to Athens to devote a few years to philosophy and literature. Soon after he had parted from his son, whom he was doomed never again to see, he was oppressed by the severest affliction, the death of his daughter in child-bed. Tullia had been thrice married; first to Piso, who died about the time of Cicero's return from exile, and then to Crassipes. For her third marriage with Dolabella both parties qualified themselves by a divorce from their consorts; and at the time of her death, arrangements for another divorce had been carried so far that her father was already applying for payment of an instalment upon her dowry.

In this new grief Cicero drew little comfort from the condolence of his friends. All the relief that he found was in reading and writing, and he composed a treatise 'Of Consolation' for himself, which was much read by the fathers of the Christian church, especially Lactantius, to whom we are indebted for the few fragments that remain. His domestic grief was completed by the misery of his ill-assorted marriage, which he was happy to dissolve after a union of less than a year. In this desolate condition he fled as usual to his books, and no period of his life produced a richer literary harvest. He has himself given us a list of the works which he wrote in this and the following year. (*De Div.*, ii., 1.) The *Orator* completed his rhetorical works, forming a sort of supplement to his three books entitled *De Oratore*, and the *Brutus*. His philosophical writings of this period were, the *Hortensius*, so called in honour of his deceased friend, in which he recommends the study of philosophy; four books in defence of the Academy, dedicated, as has been already mentioned, to Varro; five books entitled *De Finibus*, and addressed to Brutus, in which he contrasts the opinions of the different sects of philosophy on the subject of the *summum bonum;* the Tusculan disputations, in the same number of books, on a variety of points which involve the happiness of human life; three books on the Nature of the Gods; one on Divination, or the art of seeing into futurity; another on Fate; and the beautiful treatise on Old Age. These were followed by an essay on *Glory*, which has been lost since the invention of printing; the *Topica*, addressed to his friend Trebatius; and the *De Officiis*, which was dedicated to his son.

The publication of these works extended over the years 45 and 44 B.C. In the autumn of the former of these years Cæsar returned from Spain, and Cicero was induced to quit his retirement and come to Rome, where he soon after exerted his talents in the service of an old friend, Deiotarus, king of Galatia, who had incurred the displeasure of Cæsar by his firm support of the Pompeians, and indeed was charged with having formed a plot to assassinate Cæsar a few years before. Cicero failed in obtaining pardon for his friend; but his intimacy with the Dictator seemed daily to be increasing, when the Ides of March changed the whole face of affairs. Cicero was present at the scene of assassination in the senate-house, where he had the pleasure, he tells us, of seeing the tyrant perish; but the conspirators were grievously disappointed in the results of their crime. As soon as the first stupor had passed away, the public indignation drove the murderers from Rome, and Cicero himself deemed it prudent to make a temporary retreat. He proceeded first to Rhegium, then crossing to Sicily, on the 1st of August he arrived at Syracuse, whence he sailed next day, and was driven back by cross winds to Leucopetra. Here he met with some people lately from Rome, who brought him news of an unexpected turn of affairs there towards a general pacification, so that he was induced to set out immediately on his return. He touched at Velia, where he had his last interview with Brutus, and arrived at the capital on the 31st. The senate met the next morning, but Cicero, not finding things in the favourable state which he expected, was unwilling to meet Antony, and excused himself from attending, as being indisposed by the fatigue of his journey. The next day Antony was absent, and Cicero delivered the first of those orations which he called Philippics, as being rivals of the invectives which Demosthenes directed against the king of Macedon. The violence of this harangue committed him with Antony, and he again retired for security to some of his villas near Naples, where he composed and published the second Philippic. This speech, if that name can be given to what was never spoken, was a furious invective, well charged with falsehood, against the whole life of Antony, and was supposed to have been the chief cause of Cicero's death. The departure of Antony for Cisalpine Gaul left Rome again open to Cicero, who returned there on the 9th of December, and ten days after delivered his third Philippic, the chief object of which was to procure the sanction of the senate to the late proceedings of Octavianus in opposition to Antony. Having effected this object, he passed into the forum and harangued the people upon the same subject in his fourth Philippic. The ten other speeches bearing this name were delivered from time to time in the senate or the forum, to excite the people of Rome against Antony and his friends; but the prospects of the oligarchy were finally disappointed by the treachery of Octavianus and Lepidus in joining their arms to Antony, and thus sharing the whole power of the state among them. The proscription which followed, though it can in no way be justified, was levelled against men who had been themselves assassins, or the avowed advocates and panegyrists of assassination. Cicero himself had lauded the murderers of Cæsar as the greatest benefactors of their country; nay, it is doubtful whether he was not himself privy to the conspiracy, though he may have wanted the courage to use the dagger himself; and afterwards when he found Antony in his way, he repeatedly expressed his regret that the conspirators had not served up one more dish at the glorious feast of the Ides of March. Cicero was at his Tusculan villa with his brother and nephew when he received the news of the proscription, and of their being included in it. He fled to Astura on the coast, where he found a vessel ready for him, in which he immediately embarked, but was compelled by the weather to land again the same day near Circeii. The following day he embarked a second time, but again landed at Caieta, whence he proceeded to his Formian villa. In the middle of the night his slaves informed him of the approach of the soldiers who were intrusted with the murderous commission; he made an attempt to escape in a litter, but being overtaken in a wood, the scene was speedily finished. The assassins cut off his head and hands, says Plutarch, and carrying them to Rome, presented them to Antony, who had them fixed up on the rostra in the forum. Cicero was killed on the 7th of December, in the year 43 B.C.

The works of Cicero have been repeatedly published in mass, as well as separately, but perhaps the best edition of his entire writings is that by Orellius. Of his separate works the following editions deserve particular notice. The 'Variorum,' as it is called, by Graevius, containing the Orations, the Letters ad Familiares and ad Atticum with one volume of his Philosophical Works. The notes of Manutius are exceedingly valuable. 2. 'De Divinatione et De Fato,' G. H. Moser. 3. 'De Legibus,' Moser et Creuzer. 4. 'De Natura Deorum,' by the same. 5. Ditto, by Heindorf. 6. 'De Republicâ,' by Moser. 7. 'Oratio pro Cluentio,' by Classen. 8. 'Pro Milone,' by Orellius, 1826. 9. 'Pro Plancio,' by Wunder. 10. 'Orationes Philippicæ,' by Wernsdorff. 11. 'The Orations,' by Garatoni, at Naples. To those who value a correct text, Wunder's Collation of the Erfurdt MS., published at Leipzig in 1827, will be of great service. The critical writings of Madvig of Copenhagen are also deserving of study, together with his excellent 'Disputation on Asconius.' Mention has been made of the doubts as to the genuineness of certain of the Orations. F. A. Wolf has examined the claims of the four Orations, 'Post Reditum in Senatu,' 'Ad Quirites post Reditum,' 'Pro Domo sua,' and 'De Haruspicum Responsis,' in a volume published at Berlin in 1801. In the following year he published an edition of the 'Pro Marcello,' with his reasons for believing it to be spurious. In regard to the letters ad Brutum, see Brutus. The student of Cicero's writings should also possess the account of his 'Life,' by Conyers Middleton. It has been freely employed in this article, but the strong bias of the author in favour of his hero has been throughout corrected from the writings of Cicero himself, more particularly his letters to Atticus, which having been written in confidence to an intimate friend, and never intended for publication, furnish a test for trying the character of the writer such as few public men could stand with impunity. Middleton has made two great errors in forming his notion of Cicero and the men who lived in his times. He has believed all that he has said of himself, and all that he has said of his enemies; and besides this, he has, with something of disingenuity, softened down these points where he has unintentionally borne evidence against himself. The translations of Cicero's writings in English are not of great merit. One of the best is Melmoth's translation of the 'Letters;' but his style is too florid. The French language possesses an excellent translation of the 'Letters to Atticus,' by the Abbé Mongault, accompanied by a Commentary no less excellent; and the German language has a still more valuable translation of all the 'Letters' in chronological order, by Wieland, with notes, and a number of historical chapters, which are tainted however with an undue partiality to Cicero. A most laborious and useful work for the student of these times, but still retaining much of the same prejudices, will be found in the 'History of Rome, in its transition from a republican to a monarchical form of government; or Pompey, Cæsar, Cicero, and their Contemporaries,' by Professor Drumann, of Königsberg. Two volumes have alone appeared, which descend no lower than the letter C (Cornificii), for the work is drawn up in an alphabetical order according to the gentile names.

CICERO'NE, a name given by the Italians, especially of Naples and Rome, to the guides who show travellers the antiquities of the country. It was a common saying in Italy, when speaking of a learned or eloquent man, 'è un Cicerone,' 'he is a Cicero;' and the poor guides and valets de place, who, generally speaking, are neither learned nor eloquent, and often make ridiculous blunders on the most trivial subjects, have now usurped the name of Cicerone.

CICHORA'CEÆ. [Compositæ.]

CICINDE'LIDÆ, a family of Coleopterous insects, of the section *Adephaga*, and sub-section *Geodephaga*. The true carnivorous beetles are included in a large section called *Adephaga*, all the species of which group may be distinguished by their having six palpi. The section Adephaga is divided into two sub-sections, the *Geodephaga* and the *Hydradephaga*. The former derive their subsistence on the land, and the latter in the water. The structure of the insects in these two groups, in order to suit them to their habits, is therefore of necessity essentially different (as far as secondary characters of form, &c. are concerned), the former being formed for running, and the latter for swimming. In the number of joints to the tarsi (which is always five), and the antennæ (which is eleven), and the parts of the mouth, they are however alike; these latter are generally considered primary characters. To make ourselves more clearly understood, we may compare the section *Adephaga*, among beetles, to the *Carnivora* among the *Mammalia*; the *Geodephaga* to the bears, weasels, dogs, and cats; and the *Hydradephaga* to the seals and otters. We may again carry our simile further by comparing the *Cicindelidæ* to the cats or tigers, the beetles belonging to this family being most pre-eminently voracious.

The *Cicindelidæ* are divided into two groups; those species in which the emargination of the mentum is furnished with a tooth or pointed process in the middle, and those in which this process is wanting. To the first group or section belong the genera *Manticora*, *Platycheile*, *Mega* *cephala*, *Orycheila*, *Iresia*, *Cicindela*, *Dromica*, *Euprosopus*, and *Ctenostoma;* and to the second section belong the genera *Therates*, *Tricondyla*, and *Colliurus*.

The typical genus of the family we are treating of is *Cicindela*, and in this genus, as is generally (if not always) the case in typical genera, the species have a wide geographical range, and are very numerous. Taking Dejean's Catalogue as our guide, we find the genus Cicindela containing upwards of 200 species, and the number of species contained in all the other genera taken together is about 40. The species of Cicindela are found in every quarter of the globe; whereas the other genera mentioned are very local; they are all extra-European, some being entirely confined to Africa, several to South America, and others to India.

The technical generic characters of Cicindela are:—labial palpi moderately long, in this respect not exceeding the maxillary palpi; last joint of all the palpi truncated at the apex, and about the same width as the preceding joints; three basal joints of the anterior tarsi dilated in the males and covered beneath with a velvet-like substance.

As regards the form, the most striking character of the Cicindelæ is the great projection of the eyes; the jaws are very long and sharply pointed, and furnished on the inner side with three tooth-like processes; the head is generally equal in width to the thorax, or sometimes exceeding it; the thorax is either somewhat cylindrical, or rather depressed and nearly square, and is transversely indented before and behind. The elytra are generally rather depressed and almost double the width of the thorax; the legs and antennæ are long and slender.

The colouring of the Cicindelæ is generally rich and metallic; the upper surface is usually more or less shagreened, and hence is not glossy; the under surface is glossy, and generally sparingly covered with hairs of a pale colour.

With respect to their habits, it has been before remarked the Cicindelæ are extremely voracious; we may add, they are very active, and almost always take to the wing when approached, and hence are caught with difficulty; their flight is however short. The situations which they inhabit are generally sandy plains or heaths, and sometimes the sea-shore or the shores of rivers, &c.; but some of the other genera of the Cicindelidæ, from their form and colouring,* appear to be more particularly adapted to these last-mentioned situations.

Six species of the genus Cicindela have been found in England, of which the most common is *Cicindela campestris*. This insect is found more or less abundantly throughout the country, and is very common in the neighbourhood of London; it is rather more than half an inch in length, and of a bright green colour; the anterior and posterior margins of the thorax, the legs, and the basal joints of the antennæ are of a rich copper colour; the under side of the body is glossy and of a blue-green colour; the wing-cases are each adorned with six cream-coloured spots, one on the shoulder or outer angle, another at the apex, three on the outer margin at nearly equal distances apart, and one on the disc, a little lower down than the third marginal spot from the shoulder.

The larva of this insect is very well known, and may be found almost at any time during the summer in sandy situations: it lives in cylindrical burrows, varying from six inches to a foot in depth, these burrows being excavated by itself. Like the perfect insect, it is very voracious, and in fine weather may be seen with its head on a level with the surface of the soil, lying in wait for any insect which may happen to crawl over its cell. Its form is remarkable: the head is very large and slightly concave; the jaws are also large and curved upwards; the body is furnished with six legs, attached to the three first segments, and is humped near the middle of the back, at which part there are two tubercles, each of which is furnished with a horny hook; these hooks, and the body being naturally of a bent shape, enable the animal to sustain its position at the top of the cell, or to ascend and descend very quickly: the concave head and the recurved mandibles form a kind of natural basket in which the soil is brought to the mouth of the cell during the progress of its excavation.

Four other British species of the genus Cicindela, *C. sylvatica*, *maritima*, *aprica*, and *sylvicola*, have white or cream-coloured spots in the same situations as in *C. campestris*, but they are joined together in pairs; the two towards the base of the wing-case form a curved dash which surrounds the shoulder; the one on the disc of the elytron and that at the margin nearest it are also joined, and form a bent fascia, and the two at the apex form a bent dash, which follows the outline of that part of the wing-case. This disposition of the markings, viz., a lunular spot at the shoulder, a bent fascia in the middle, and another lunular spot at the apex of the elytron, is that which is most commonly found in the species, and the most common colour is brownish bronze; such is the colour of *C. maritima*, *riparia*, and *sylvicola;* the latter sometimes varies to a green hue

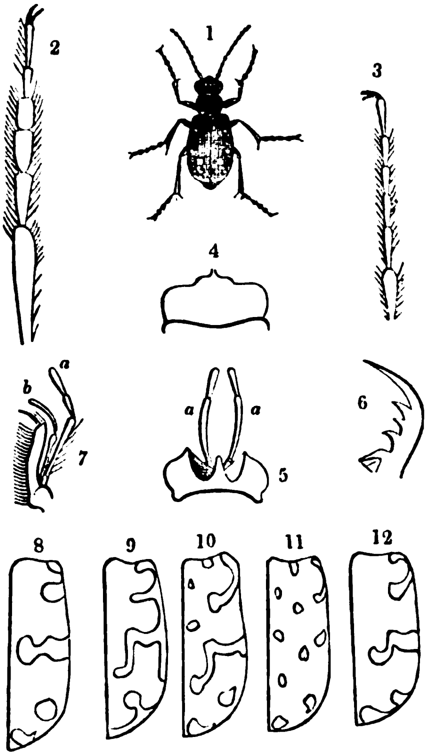

Fig. 1, Cicindela campestris; *fig.* 2, anterior tarsus of the male; *fig.* 3, do. of female; *fig.* 4, labrum of another species of Cicindela; *fig.* 5, mentum of do; *a*, *a*, labial palpi; *fig.* 6, mandible; *fig.* 7, maxilla, *a* external maxillary palpa, *b* internal maxillary palpa; *figs.* 8, 9, 10, 11, and 12, wing-cases of five different species of Cicindela, to show the variation in the markings.

In some exotic species of Cicindela the elytra are adorned with numerous spots; eleven is the greatest number we have found; of these, however, three or four are often obliterated, and the others are joined (two or three together), so as often to form three irregular-shaped oblong dashes or fasciæ.

In some instances the markings run one into the other, so that there is more white than ground colour; and in one species, now before us, the wing-cases are entirely white. These markings vary but slightly in individuals of the same species.

The Cicindelidæ, in most arrangements of insects, form the first family of the Coleoptera.*

CICISBE'O, in Italian, means a gallant, a man who courts the ladies. The term is also applied to a knot of ribands, which used to be worn appended to the hilts of swords or to the handles of fans. (*Dizionario della Crusca.*) In like manner a Cicisbeo is a man who hangs upon a lady, is constantly by her side and at her beck, and attends her wherever she goes. This derogatory custom has long prevailed with married ladies, especially in the towns and among the fashionable classes, in Italy and other southern countries; but the country people and the humbler class of citizens have generally remained free from it. Even in the towns the practice is losing ground of late years. The words *cavalier servente* and *patito* are also used in the same sense.

---

* The colouring of insects, as well as their form, often affords a clue to their habits.

* We have entered more than usually into detail in this article, because the insects here treated of constitute a group in which cabinets are very rich in species; it therefore affords good illustrations of various points of general application in entomology which it may be hereafter necessary to refer to. Whilst writing this, and in endeavouring to trace the markings of the various species of Cicindelæ to one source, we have discovered (upon referring to other families of the Coleoptera also) that in most beetles, where markings occur, they may be traced to variations of one pattern.

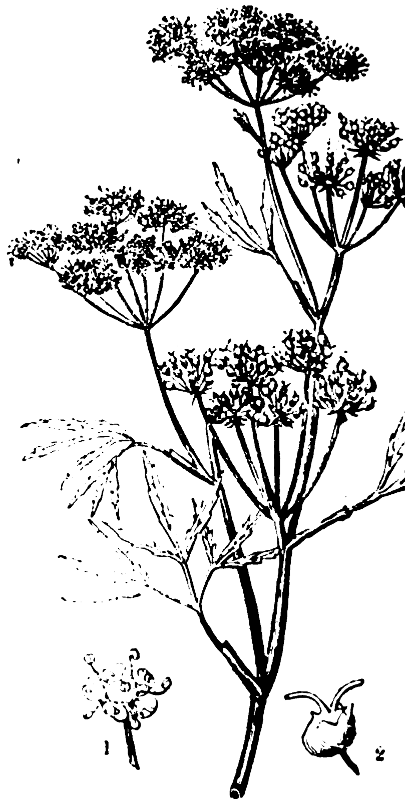
CICOGNA'RA, COUNT LEOPOLD, was born at Ferrara, November 26, 1767, and, although the inheritor of considerable wealth, began early to distinguish himself by his application to study. While yet a youth he made considerable proficiency in mathematics and physics, whereby he recommended himself to the notice of Spallanzani, Scarpa, and many other eminent individuals at the university of Pavia. Having completed his course of studies there he proceeded to Rome, where he occupied many years not only in studying the great works of art, but likewise in practising himself both in drawing and painting, for which he had almost from his boyhood manifested more than ordinary talent. After visiting Naples and Sicily, in which latter country he published, at Palermo, his first literary effort, a poem, entitled *Le Ore del Giorno*, he successively visited Florence, Milan, Bologna, and Venice, for the purpose of making himself thoroughly acquainted with the various treasures of art in those cities. In 1795 he fixed himself at Modena, and during the twelve following years appears to have given much of his attention to public affairs, having been for some time minister at the court of Sardinia. He resigned his post in 1808, when he was made president of the Academy of the Fine Arts at Venice; an office for which he was well qualified no less by the public-spirited zeal with which he discharged it than by his knowledge of art itself and the literature belonging to it. From this epoch in his life may be dated the commencement of his career as a writer, during which he enriched the branch of literature just mentioned by many important works. In that same year (1808) he published a treatise on 'The Beautiful' (*Il Bello*). This was succeeded by his great work, 'The History of Modern Sculpture' (*Storia della Scultura dal suo risorgimento in Italia al Secolo di Napoleone*), an undertaking to which he had been urged by his friends Giordani, D'Agincourt, and Schlegel. It is in three folio volumes, the first of which appeared in 1816, and the last in 1818, and contains about 180 outline plates, exhibiting a vast number of subjects from the earliest period—the age of the Pisani and Donatello—to that of Canova, to a notice of whose works the whole of the seventh or last book is devoted. Although fastidious criticism has taxed it with some defects, it is undeniably a performance of great research and erudition, bringing down to the present century the history of the art from the point at which it had been left by D'Agincourt, who himself had taken it up where Winckelmann had quitted it. Besides a vast body of information as to the professed subject, this work also embraces much subsidiary matter of great interest, particularly the descriptive and historical notices of St. Mark's at Venice, the cathedrals of Milan and Orvieto, St. Peter's and many other Basilicæ.

His next publication was a catalogue raisonné, in two thick 8vo. volumes, of his own library, an immense collection of works in every department of the fine arts. This is a most valuable addition to bibliography, and shows that Cicognara spared no cost in the pursuit of his favourite studies. He likewise produced a work entitled *Memorie per servire alla Storia della Calcografie*, and numerous articles relative to subjects of art and artists, printed in various journals, but never, unfortunately, given afterwards to the world in a collective form. Even had he produced none of the works above enumerated, the name of Cicognara would have been transmitted to posterity with honour by the two splendid architectural volumes, entitled *Le Fabbriche piu Cospicue di Venezia*, 1815—20, of which the greater share of the literary part and the chief conduct of the work belong to him, although he was assisted in it by Diedo and Selva, who furnished the accounts of many of the buildings. It is illustrated with 250 engravings, wherein will be preserved all the most interesting structures of Venice when the now-mouldering originals shall have fallen into utter decay.

He died at Venice, of a disease of the lungs, March 5, 1834, and his obsequies were performed with great solemnity in the cathedral of St. Mark.

CICO'NIA. [Storks.]

CICU'TA VIRO'SA, or WATER HEMLOCK, is a wild poisonous plant of the Umbelliferous order, found occasionally by the sides of ditches and ponds. It is a perennial plant, with a large fleshy white root covered externally with fibres, and divided internally into several low chambers filled with a milky or yellowish juice. The stem is erect, hollow, cylindrical, striated, and two or three feet high. The leaves, especially the lower ones, are decomposed or thrice-pinnated; the leaflets are narrow, lanceolate, deeply and irregularly toothed. The umbels are usually destitute of involucre, or, if they have one, it is nothing but a single linear bract; the partial umbels have several such bracts. The flowers, which are white, have the ordinary umbelliferous structure. They are succeeded by globular double fruit, crowned by the style and the five teeth of the calyx, and showing on each of their convex faces five salient simple angles. Its medicinal properties are similar to those of common hemlock [Conium], but more energetic. Its roots have been mistaken by children and country folks for parsnips, and have been eaten with fatal consequences.



[Cicuta virosa.]

1. A flower. 2. A young fruit.

CICUTA. [Conium.]

CID. The adventures of this famed Castilian hero are nearly as much involved in fable and romance as those of our King Arthur and his Knights of the Round-table; nor is it easy, at this distance of time, to separate the truth from the exaggeration of tradition and the inventions of ballad-writers. Ferreras and one or two other Spanish writers think, however, they have established the following facts.

The Cid (from the Arabic *El Seid*, 'the Lord'), so called by the Moors of Spain whom he subjugated by his victories, was born at Burgos somewhere about 1040. His real name was Rodrigo Diaz de Bivar. He attached himself to Sanchez II., king of Leon and Castile, whose life he once saved in battle. At the siege of Zamora Sanchez was treacherously slain, and his brother Alfonso, the next in order of succession, was suspected of the deed. The Cid insisted that, before taking possession of the vacant throne, Alfonso should purge himself by taking an oath of his innocence of his brother's murder; and when the rest of the nobles hung back, he alone exacted and made the king repeat the vow, to which he added the most awful maledictions in case of perjury. After such a step he could expect little court favour, and the state of Spain encouraged his propensities to war and adventure. His life was a continued series of combats with the Moors, who occupied by far the largest and richest parts of the country. He fell upon them in Aragon, burning, plundering, and slaughtering wherever he went; he took Alcoçer, and making that place his strong-hold, he was gradually joined by a numerous band, half patriots, half freebooters, with which he made innumerable incursions into the neighbouring territories of the Moors. Still gathering force he penetrated to the district of Ternel, at the south-western extremity of Aragon, and there established himself in a strong fortress on a rock, which is still called 'La Peña de el Cid' (the rock of the Cid). By the sudden death or murder of the Moorish lord of Valencia, he was encouraged to extend his incursions into that province, and to the shores of the Mediterranean. Here, too, he was eventually enabled to establish himself. After a long siege he took Valencia, the capital city, and held it until his death, which happened about 1099.

It appears the Cid really had a wife named Ximena, the Chimène of the celebrated French tragedy 'Le Cid,' but the story of his affecting courtship, and the struggle and contrast of affections in the heart of his mistress, are mainly inventions of Corneille. The Spanish Chronicles and ballads, from which the French tragedian took the notion of his plot, or from a drama founded upon them, do indeed relate that the Cid had killed Ximena's father; but they destroy all interest in the heroine by saying that after her father's death, and before any tender addresses on the part of his slayer, she earnestly begged the king to marry her to the Cid, 'because,' she is made to say by these naïve writers, 'I am quite certain that his possessions will one day be greater than those of any man in your dominions.'

The original 'Cronica de el Famoso Cavallero Cid Ruy Diaz Campeador' is supposed to have been written in the 13th century, about 150 years after the hero's death. Mr. Southey, in his curious work, makes use of a printed edition of 1593, and says the first and only other edition was printed in 1552; but there is a copy of an edition in the library of the British Museum which bears the date of 1541.

The 'Poema de el Cid,' which is believed to contain rather more historic truth than the prose chronicle, was written about the middle of the 12th century, or only some 50 years after the Cid's death. The author has been called the 'Homer of Spain,' but his name has not been preserved. Mr. Southey says his work is unquestionably the oldest poem in the Spanish language, and (in his opinion) the finest beyond all comparison. This praise is perhaps extreme, but the 'Poema' contains some powerful passages, and is highly interesting from its undoubted antiquity.

Besides this poem the Spaniards have an immense number of romances and ballads relating to the exploits of the national hero. No fewer than 102 of these are in the real old style of the 13th and 14th centuries; many are evidently more modern, and many more have never been printed. In some of these ballads the wonderful achievements of Bernardo de el Carpio, Ferran Gonzalez, and the rest of the twelve peers (for Spain had her twelve *peerless* knights, as well as Britain and France) are interwoven with the adventures of the great Cid. An ample notice of these different works will be found in Mr. Southey's 'Chronicle of the Cid,' 1 vol. 4to., 1808.

CIDARIS. [ECHINIDÆ.]

CIDER, or CYDER. A word used to signify the juice of apples expressed and fermented. The article APPLE contains a general view of the culture of apple-trees; what is here stated as to the management of apple-trees has special reference to the English cider counties.

In the Hereford district (under which name we shall refer to that county with the adjoining cider districts in Gloucestershire, Monmouthshire, and Worcestershire, while by the name of the 'Devonshire district' similar portions of Dorsetshire, Somersetshire, and Cornwall will be distinguished), where the varieties of cider-apple cultivated are far more numerous than in any other part of England, the New Foxwhelp (a seedling from the old), the Wilding, the Cherry Pearmain, the Yellow and Red Norman,* are among the many sorts that are preferred. It appears to be almost immaterial whether the crab-stocks are grafted before or within a short time after they are removed from the nursery to the orchard in which they are to stand. In Herefordshire it is usual to insert the grafts about six feet from the ground, and to plant the trees about 66 feet between the rows, and 36 between the trees where the soil is rich; if the soil is poor, less distance is allowed, as the trees will not spread with so great vigour. This seems a preferable method to that practised in Devonshire, where the grafts are inserted at from three to four feet from the ground, and the trees planted about 16 feet apart. The advantage which in Devonshire is gained from the trees being less exposed and broken by the wind, and perhaps from a greater produce of apples, is more than counterbalanced by the entire loss of the land, usually a wilderness of weeds, into which horses run in the winter, and calves in the spring, but where neither grown cattle nor the plough can ever be admitted. In the Devonshire district, the situations chosen for orchards are generally hollow dells or shelving banks, in the neighbourhood of the farm-houses, the land on which they are planted being put to little other use; while in the Herefordshire district the choice is determined chiefly by the quality of the soil, without reference to the position of the farm-house. In their youth the trees do comparatively little injury to the land, while they receive considerable benefit from the frequent stirring by the plough of the soil round their roots, so that newly-ploughed lands, or hop-yards which may be again laid down to grass as soon as the trees have acquired some strength, are spots frequently chosen. This practice is agreeable to the very sensible instruction given by Mr. Marshall, *Rural Economy of Gloucestershire*:—'Plant upon a recently broken-up worn out sward; keep the soil under a state of arable management until the trees be well grown, then lay it down to grass, and let it remain in sward until the trees be removed and their roots decayed, when it will again require a course of arable management.' (vol. ii., p. 302.)

In February or March, or, where the soil is light, in October or November, holes should be dug about six feet in diameter, each being adapted in depth to the root of the tree that it is to receive. The best earth, with the turfs, if the spot is grass land, should be thrown into the bottom of the hole, and the roots of the tree separated with the hand in horizontal layers with the richest mould between them; all the earth may then be thrown in and firmly trodden down. If the stocks are strong, the best and cheapest method of protection from the injuries of cattle is a frame of willow staves, about six feet long, cleft as those used for the bars of hurdles: these should be hammered about six inches into the ground, round the tree, and as near it as can be done without injuring the roots, perhaps three inches from it: the staves should then be nailed together with two bands of narrow iron hooping, one a foot and a half from the bottom, another at a like distance from the top, at the same time binding them round the tree as tightly as can be done without injury to the bark. Where the stocks are not strong, the best fence is 'one large post, slit with a saw and placed flat-way, with the faces to the plant, and about two feet apart, with rails on each side, nailed upon the edges of the posts.' (Marshall.) In the Hereford district these fences are much used; they are cheap and effectual, and from their narrowness offer little impediment to ploughing and other purposes of agriculture, which are here carried on as much in the orchards as in any other lands.

Very little attention is paid to enriching the soil round the trees when once they have been planted. In Devonshire it is common to see the weeds which are cropped in the orchards, heaped near the stem, there to decay and nourish the roots; and in Herefordshire the more careful planters cause the earth to be dug once a year round trees that have been recently planted: neither is there so much care taken with the trees themselves when they have once grown strong, as the benefits which have been derived from a better system of management would warrant. In by far the largest proportion of orchards, with the exception of gathering the fruit, nothing is done to the trees from the beginning of the year to the end. To remove superfluous wood by judicious pruning (an art of which many that practise it are most mischievously ignorant), to remove part of an excessive crop of fruit, to cleanse from moss and mistletoe, which latter in frosts forms excellent food for sheep, are practices too frequently neglected.

The fruit of the different varieties of apple ripen at different times of the year, earlier or later, according to the season. Among the earliest are the Codling and American Must, which begin to fall from the trees at the end of September; and while the majority attain their maturity about the end of November or the middle of the following month, there are some from which the apples will not fall until six or eight weeks later. The customary method of picking the fruit is by striking the trees with poles, provincially called 'poulting,' and then gathering the fallen apples; but though this practice is almost universal it is frequently mischievous, from the young bearing wood being broken by the violence that is used. It is better economy to pay a small extra price for collecting the fruit which falls at several times, than to injure the trees by knocking down all the fruit, the unripe as the ripe, to save a few shillings. The apples will fall by degrees, and at intervals a boy may be sent into the trees to shake the branches: in all practicable cases the use of the pole should be avoided. When the apples have been gathered, each sort by itself is collected into heaps, about ten inches deep, where they remain for a month, or more, until they become mellow; they are then ready for the mill.

---

* It has been objected to 'Norman' cider, that it will not carry to a distance without damage.

Cider is manufactured with very rude machinery, by the following process. The apples are thrown into a circular stone trough, usually about eighteen feet in diameter, called the *chase*, round which the *runner*, a heavy circular stone, is turned by one or sometimes two horses. When the fruit has been ground until the rind and the core are so completely reduced that a handful of 'must' when squeezed will all pass without lumps between the fingers, and the maker sees from the white spots that are in it that the pips have been broken, a square horse-hair cloth is spread under a screw-press, and some of the must is poured with pails upon the hair, the edges and corners of which are folded inwards so as to prevent its escape. Ten or twelve of these hairs are piled and filled one upon the other, and then surmounted with a frame of thick boards.[*] Upon this the screw is slowly worked down by a lever; and with the pressure, a thick brown juice exudes from the hairs, leaving within them only a dry residue, which, in years when apples are scarce, is sometimes mixed with water, ground again, and the liquid pressed out as before. This latter product is called 'water cider,' a thin unpalatable liquor, which is given to the labourers early in the year.

The cider is received by a channel in the frame of the press upon which the hairs stand, emptying into a flat tub called a 'trin.' From the trin it is poured with buckets or 'racking cans' into casks, placed either out of doors, or in sheds where there is a free current of air. In about three or four days, more or less according to the heat of the weather, the liquor usually will ferment; the thick heavier parts will subside as a sediment at the bottom of the cask, and the lighter become bright clear cider. This should then be 'racked' or drawn off into another cask, and the sediment be put to strain through linen bags, and what oozes from them should be restored.

It is during the fermentation that the management of cider is least understood, and there is the greatest hazard of injury. It is necessary also to know what fruit will by itself make good cider, which kinds should be ground together, and what proportions should be mixed. But it is in the preservation of strength and flavour after the cider is ground that the principal difficulty consists: *slight* fermentation will leave the liquor thick and unpalatable; *rapid* fermentation will impair both its strength and durability; *excessive* fermentation will make it sour, harsh, and thin. Other things being equal, that cider will probably prove the best in which the vinous fermentation has proceeded slowly, and has not been confounded with the acetous. The remedies used in cases of cider not clearing are either yest or the addition of cider in a state of fermentation, isinglass, eggs, or a quart of fresh blood stirred up with the liquor, in which last case it is to be racked on the following day; these do not always prove effectual. But the common evils are excess or rapidity of fermentation; and if a better quality than farm-house or 'family drink' is sought, cider requires so much care to prevent its being spoiled, that the best and most careful makers frequently have it looked at during each night for some weeks after it is made; and if the bubbling hissing noise, the sign of fermentation, becomes frequent or too loud, the liquor is *immediately* racked off into another cask: this check often requires to be repeated several times; but although at each racking some portion of the strength will be lost, the body, flavour, and sweetness will chiefly be retained. It is not the habit of the farmer to add sugar, treacle, brandy, or any colouring matter to the liquor: it is only adulterated in the hands of cider dealers and publicans, who will not lose a hogshead, and if one has turned sour, or has been otherwise damaged, it must be 'doctored,' in order to render it marketable.

At the beginning of January the cider is moved into cellars, where by large growers it is frequently stored in casks of great capacity, containing 1000, 1500, or even 2000 gallons; these are cheaper in proportion than smaller vessels, and are thought to preserve the cider better. In March the liquor is bunged down; it is then fit for sale, and may be used soon afterwards, though it will greatly improve by keeping. If bottled cider is required, it should be bottled and wired in the September or October after it is made; some persons prefer an earlier time, the end of April or the beginning of May; a greater degree of effervescence is thus attained, but a considerable loss accrues from the number of bottles that will burst.

In 1830 the tax upon cider of ten shillings a barrel was taken off (M'Culloch, *Dic. Com.*), and in the same year an Act was passed allowing any person to sell cider upon the payment of 2*l.* 2*s.* annually for a licence from the Excise. This act was amended in 1834, and a licence for the sale of cider is now (1836) granted by the Excise to an application signed by six ratepayers of the applicant's parish, the payment being 3*l.* 3*s.* if the liquor is to be drunk on the premises, 1*l.* 1*s.* if it is not. These alterations have necessarily added greatly to the consumption; but the increase of orchards during the last twenty years, and the late productive seasons, have fully supplied the demand. During the years 1833-4-5 the price in the hands of the grower may be thus estimated:—Of the best cider, from 1*s.* to 1*s.* 6*d.* per gallon; good, from 10*d.* to 1*s.* per gallon; family cider used by farmers and in public-houses, from 4*d.* to 10*d.* per gallon; 'drink' for labourers, from 2½*d.* to 6*d.* per gallon. These prices amply remunerate the farmer, who, in many instances, might increase his profits by a diminution of the cost of production. It cannot certainly be supposed that small growers can go to the expense of procuring much machinery; nevertheless the extreme clumsiness of the present wasteful system would fully warrant larger owners in erecting suitable buildings and apparatus. It is true that some improvements have been made, that larger mills are used, that in the press an easily worked iron screw has been substituted for an awkward wooden one; but far more remains to be effected. If the mill was placed upon a first floor, which could easily be done in a building erected against a bank, or having an inclined plane, so that horses might enter at that height, all lifting of the cider from the trin might be saved, as a pipe might be carried from the press into casks in the cellars underneath. Again, if the casks in the cellars were placed upon stages, manual labour in racking might be dispensed with, and waste from spilling saved, since a pipe from a hogshead upon a high stage would empty the liquor into a cask on a lower. No use, again, is made of the siphon, a cheap instrument within the reach of any farmer's purse, which would no doubt be serviceable and economical.

The quantity consumed by workmen is very large: two or three quarts a day is the usual allowance given in Herefordshire by masters; and in harvest-time many labourers drink in a day ten or twelve quarts of a liquor that in a stranger's mouth would be mistaken for vinegar; they do not like sweet cider. Notwithstanding so great a quantity is consumed, there do not appear to be any diseases peculiar to or very general in cider countries: idiocy and rheumatism have been stated to be very prevalent in such districts; but even if this is true, cider-drinking has in no way been proved to be the cause. It is remarkable that during the continuance of the cholera in this kingdom, there occurred very few cases in Devonshire, and none in Herefordshire, although the sickness reached the adjoining counties at the time of harvest, when cider is drank to excess.

Cider of good quality is made in Ireland, in the counties of Waterford and Cork; in Normandy, whence we have many of our best apples; in Belgium; and of inferior quality in Germany. It is also made in abundance, and of excellent quality, in many parts of the United States.

CIGAR. [TOBACCO.]

CIGNA'NI, CARLO, was born at Bologna, May 15, 1628. His father was a notary, but claimed his descent from an old Ghibelline family of Florence, who had been driven from their native city by the Guelphs. Carlo, who showed an early taste for painting, was put under Giambatista Cairo for instruction. He soon surpassed his master, and was removed to the care of Albani, under whom he rapidly rose in reputation and success. He subsequently enlarged his style of painting by a careful study of the works of Correggio and Annibal Carracci, from whom he learned the art of giving size and space to his pictures, by means of a powerful and skilful use of *chiaroscuro*. Le Brun is said to have been deceived by a picture of his, and to have taken it for the work of his great countryman. Cignani had a singular degree of prosperity; commissions crowded upon him, he enjoyed the friendship and correspondence of many of the reigning princes of his time, and acquired great wealth. He was also made a count by Ranuzio II., his native sovereign.

---

[*] This is the process in the Hereford district. In Devonshire a lever press is used and 'reed,' unthrashed straw, is spread in layers in the place of hairs. The method used in the south of France for expressing oil from olives is identically the same.

Being invited to paint the Duomo of Forli, he removed thither with his family, and resided there for the remainder of his life. While Forli was occupied by some German troops during the war between the pope and the emperor, Cignani presented a picture to the commander of the forces, who in return, besides a handsome gift in money, issued an extraordinary order to his troops to refrain in every way from molesting the good people of the city. The citizens testified their gratitude to Cignani by enrolling him among their nobility. In 1708, when the Clementine Academy was instituted, Cignani was elected president. He died September 6, 1719, leaving two sons, one of whom, Felice, was a painter.

He painted an infinite variety of subjects, sacred, classical, and even comic. His colouring is pleasing and brilliant, and his finish most elaborate. His chief work is the Duomo at Forli, an immense composition, ingeniously disposed, which represents the assumption of the Virgin. (Zanotti; Zanelli.)

CILICÆA. [ISOPODA.]

CILICIA (Κιλικία), a country of Asia Minor, forming part of Anatolia. The antient boundaries were, on the north the Taurus, which separated it from Cappadocia and Lycaonia, on the south the Mediterranean sea, on the east Mount Amanus, which separated it from Syria, and on the west Pamphylia. According to Herodotus (v. 52), the Euphrates was the boundary of Cilicia and Armenia. Cilicia antiently comprised two divisions, the names of which were derived from their physical character. The west division was called mountainous or rough Cilicia (*Κιλικία τραχεῖα*, or, Herod. ii. 34, *ἡ ὀρεινὴ Κιλίκιη*, Cilicia aspera), and the east division, level Cilicia (*Κιλικία πεδιάς*, Cilicia campestris). Many attempts have been made by antient and modern writers to account for the name Cilicia; the Greeks derived it from Cilix, son of Agenor, who was said to have colonized this country (Herod. vii. 91). The inhabitants were formerly called Hypachæi (*Ὑπαχαιοί*), according to Herodotus (vii. 91). For our information on the geography of Cilicia we are chiefly indebted to Strabo (book xiv.), and Beaufort's survey of the line of coast as far east as the gulf of Issus (Scanderoon). With the interior we are very little acquainted; the principal towns which are known are on the coast. Level Cilicia is described as fertile: mountainous Cilicia has always been famous for a fine breed of horses; and the annual tribute of the Cilicians to Darius consisted of 360 white horses and 500 talents of silver (Herod. iii. 90).

The first town in mountainous Cilicia, on leaving Pamphylia, was Coracesium, according to Strabo (pp. 667, *d*, 670, *a*, Casaubon). The modern name is Alaya; it is a strong natural fortress, situated on a high and almost insulated rock. Coracesium held out against Antiochus (Livy, xxxiii. 20; Beaufort's *Karamania*, pp. 160—168).

The next town of importance is Selinus (*Σελινουντ-ος*), situate on a steep hill. The emperor Trajan died there, and the town was afterwards called Trajanopolis: the modern name is Selinty. Cape Anemurium (now Anamour) is the most southern point of Asia Minor; and probably from this circumstance (as Captain Beaufort suggests, p. 192) derived its name, which means 'windy point.' The small town and port of Celenderis (now Chelindreh) lies between Anemurium and Seleucia, the modern Selefkeh. The ruins of the antient Seleucia are many miles from the shore, on the west side of the river Calycadnus (Ghiuk Sooyoo), which now at any rate flows into the sea a few miles east of Cape Zephyrium (Beaufort, p. 226). This coast appears to be still as much infested by pirates as it was in the time of Strabo (pp. 671, *b*, 684, *c*). The shore presents a line of noble promontories and white marble cliffs rising perpendicularly from the sea. This rocky character diminishes a few miles west of Selefkeh, where the high lands begin to recede from the coast. Many rare kinds of animals and birds are found on the coast, and almost every district is said to have some peculiar to itself (Beaufort, p. 209). In the time of Cicero, Cilicia was famous for panthers.

There is no town of much importance between Selefkeh and the river Latmus (now Lamas), which was the boundary of mountainous Cilicia (Strabo, p. 671, *c*). Here the rocks and cliffs cease, and are succeeded by a gravelly beach and broad plains, which extend to the mountains. The principal towns in level Cilicia were Soli, Tarsus or Tarsi, and Issus or Issi (Xenoph. *Anab.*, i. 2, 23, 26). Soli was afterwards called Pompeiopolis, because Pompey settled the remains of the pirates there: the modern name is not ascertained; perhaps it is Menetlu (Captain Beaufort, p. 255). This town was the birth-place of Chrysippus, and of the poets Philemon and Aratus (Strabo, p. 671, *d*). Tarsus, antiently one of the most celebrated cities in Asia Minor, still bears a respectable rank: its modern name is Tersoos. Tarsus was the birth-place of the Apostle Paul, and a school for the study of philosophy and the arts. According to Strabo (p. 673, *d*), it was a superior school to Athens and Alexandria.

Tarsus stood in a plain on the banks of the Cydnus, now called the Tersoos river. The water of the Cydnus, as of the other rivers along this coast which carry down the melted snow from the ridges of Taurus, is extremely cold: injudicious bathing in it proved fatal to Frederick Barbarossa, and nearly so to Alexander the Great. The Cydnus has undergone a great change from the deposits carried down from the mountains: formerly it received large ships of war; now none but the smallest boats can enter it (Capt. Beaufort, p. 265). Issus is situated in the extreme eastern part of the plain of Cilicia, at the head of the Issic gulf, called the gulf of Scanderoon: here Alexander defeated Darius, B.C. 333. The river Pyramus (the modern Jyhoon), between Tarsus and the plain of Issus, has brought down such a quantity of sand and earth, that the river has been diverted twenty-three miles from its antient course (Captain Beaufort, p. 275): in Strabo's time the Pyramus entered the sea a little to the east of Cape Megarsus (Karadash); now the mouth is not much west of Ægææ (Ayas). Strabo (book xii., p. 536, *a*) says that it passes under ground for a great distance, and bursts forth again through a cleft of Mount Taurus: he was well aware of the immense deposits which were brought down by the stream.

The origin of the Cilicians is uncertain: they were probably a Phœnician colony (Herod. vii. 91). Their character in historical periods did not stand very high; and in this respect they were commonly classed with the Cappadocians. They were the only nation within the Halys, except the Lycians, whom Crœsus did not reduce (Herod. i. 28). Our earliest information represents them as governed by kings; and when Cilicia became one of the Persian satrapies, it evidently continued to be governed by native kings, subject of course to the Persian empire. The name of one of the Cilician kings, Syennesis, is familiar to the reader of Xenophon's 'Anabasis' (i. 2), and he was not the first of his name. Herodotus (i. 74) mentions one as contemporary with Alyattes; and Æschylus (*Pers.* 326, Dindorf) has immortalized the bravery of another, who joined Xerxes in his expedition against Greece.

Cilicia became a Macedonian province on the downfall of the Persian empire; Seleucus and his descendants, after the death of Alexander, held the sovereignty till Pompey reduced the level country to a Roman province. Cicero was proconsul of Cilicia A.U.C. 702; and for his success against those who had fortified themselves in the mountains, and had held out against his predecessor Appius Claudius Pulcher, he was rewarded on his return with a triumph. Till the reign of Vespasian, mountainous Cilicia appears to have been governed by kings who were appointed by the Romans, but after that time it became a province. (Strabo, xiv., pp. 668—676, Casaub.; and Beaufort's *Karamania.*)

CILI'FERA. [MICROZOARIA.]

CILIO'GRADA, an order of *Acalephans* instituted by De Blainville, and comprising the *Ctenophoræ* of Eschscholtz. The following is De Blainville's definition in his 'Actinologie,' where he admits that the distribution of the species of one of the genera (*Beröe*) adopted by him in the article 'Zoophytes' in the 'Dictionnaire des Sciences Naturelles,' according to the number of ambulacra, depended upon an erroneous observation, and consequently prefers that given by Eschscholtz, founded on the disposition of the *cilia*, at the same time considering Eschscholtz's genera *Pandora* and *Medea* in no other light than as simple divisions of the species.

Body gelatinous, very contractile, free, diversiform, evidently binary or bilateral, sometimes appearing subradiated, provided with a kind of straight ambulacra, formed by the approximation of two series of vibratory cilia.

Intestinal canal complete, or provided with two orifices, a mouth and a vent.

Before we proceed further, it will be necessary to inquire into the nature of the cilia above mentioned, with which, or, at least, with locomotive organs closely resembling them, many of the *Medusæ* are provided, though with certain modifications. Eschscholtz describes these cilia as pectinated or comb-like organs, arranged in longitudinal rows on the external surface of the body with their flat surfaces in contact. Each is made up of many small, flattened, pointed filaments, united by a common base, the points being directed towards the posterior extremity of the body. They are endowed with a motion not unlike the fins of fishes, and are slowly raised but suddenly struck back, whereby the body is carried through the water. In *Beröe* and its congeners the cilia are directed towards the closed extremity of the body, so that the opposite or open end is carried forward. The Ciliograde appears to have the power of enforcing a partial or total action of these organs at pleasure, so as to enjoy other motions besides that of direct progression. When separated from the body with a piece of the skin the cilia continue to move, as is observed in the article BERÖE. Under each of the rows runs a longitudinal vessel, which communicates with the rest of the vascular system, and contains a fluid, in which there are yellowish particles. Eschscholtz looks upon these as arteries, and regards the cilia as respiratory organs in addition to their locomotive functions; Schweigger compares the vessels to the canals communicating with the tubular feet of *Echinus* and *Asterias*; and Dr. Grant inclines to think that the motion of the cilia, whose filaments he conjectures to be tubular, is due to their alternate fulness or emptiness of fluid derived from the longitudinal vessel, like the tubular feet of the *Echinodermata*. Whereupon Dr. Sharpey well remarks, 'This view of their mode of action, however, is scarcely reconcilable with the observed phenomena. Audouin believed that in the *Idya*, a genus nearly allied to the *Beröe*, the fluid of the longitudinal vessel, which he supposes to be water, is sent into the cilia; he therefore regarded them as respiratory organs. If the vessel under the cilia in this case, as in the *Beröe*, communicate with the rest of the vascular system, and its contained fluid be regarded as blood, then the cilia of the *Idya*, which, according to Audouin, are permeated by the fluid, would bear a certain analogy to the gills of fishes.' But our limits do not permit us to pursue this part of the subject farther, and we must therefore refer the student to the lately published and elaborate works of Professor Purkinje and Dr. Valentin, and of Dr. Sharpey.

De Blainville, who acknowledges that he has never studied the *Ciliograda* in a living state, and that he only knows them from figures and descriptions, or at best from some specimens preserved in spirits of wine, which he owes to MM. Quoy and Gaimard, says that, nevertheless, he has no doubt that they ought to be withdrawn from the class *Arachnodermaires*, wherein they have hitherto been placed by all zoologists. He observes that he cannot venture to assert whether they ought to pass to the type of the *Malacozoaria*, or whether they ought not to remain near the *Holothuriæ*, and adds that it is a subject of research which can only be terminated by investigation in the living subject

De Blainville goes further:—'A sufficiently great number of persons,' he remarks, 'have spoken of the *Ciliograda*, but voyagers have been nearly salways the persons who have observed them—in a living state, it is true—but incompletely. I do not know even one zoologist who has published 'quelque chose d'un peu rationnel' upon their organization. What we know is limited to some details as to their mode of locomotion. Thus, we learn from those who have seen them in the sea, that the *Ciliograda* are gelatinous transparent animals, continually agitating the cilia with which their very contractile body is provided, organs which possess the phosphorescent faculty in the highest degree. They float thus continually free, and swimming in the waters of the sea at sufficiently great distances from the banks. For the rest, we are ignorant of the nature of their food, of the mode of their generation, and other circumstances of their manners and habits.' The work wherein this passage appears was published in 1834, and though we by no means would have it understood that there is not still a great deal to be done before the whole of the organization of the *Ciliograda* can be satisfactorily elucidated, we cannot agree with M. de Blainville's assertion of the entire state of ignorance which he would have us believe, prevails on the subject. In addition to the interesting labours of other observers, some of whom we have already mentioned, Fabricius had detected minute crustaceans in the digestive organs of *Beröe*, and thus furnished a key to the nature of the nourishment of that genus; and an abstract of Dr. Grant's paper 'On the Nervous System of *Beröe Pileus*' was published in the 'Proceedings of the Zoological Society of London' early in 1833.

Geographical Distribution.—M. de Blainville says that *Ciliograda* exist in all the seas; but that it seems to him that they are most abundant in those of the north, perhaps, he adds, because they have been neglected.

SYSTEMATIC ARRANGEMENT.

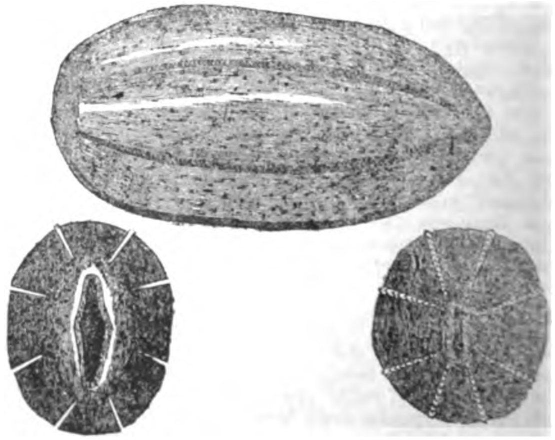
De Blainville, whose amended arrangement we take, observes that systematists have hitherto agreed to imitate Gmelin more or less on the subject of the place of the *Ciliograda* in the animal series, that is to say, in making them a genus approximating to the *Medusæ*; and he instances Lamarck, Cuvier, Latreille, and Oken, as not having expressed any doubts on the subject.

Genera. Beröe.

a.

Species whose cilia are smaller than the interstices which separate them (Genus Beröe of Eschscholtz).

Example, *Beröe ovata*. Those found by Browne seldom exceeded three inches and a half in length, or two and a half in the largest transverse diameter. 'This beautiful creature,' says Browne, *Jamaica*, p. 384, 'is of an oval form, obtusely octangular, hollow, open at the larger extremity, transparent, and of a firm gelatinous consistence; it contracts and widens with great facility, but is always open and expanded when it swims or moves. The longitudinal radii are strongest at the crown or smaller extremity, where they rise from a very beautiful oblong star, and diminish gradually from thence to the margin: but each of them is furnished with a single series of short, delicate, slender appendixes or limbs [the cilia] that move with great celerity either the one way or the other, as the creature pleases to direct its flexions, and in a regular accelerated succession from the top to the margin. It is impossible to express the liveliness of the motions of those delicate organs, or the beautiful variety of colours that rise from them while they play to and fro in the rays of the sun; nor is it more easy to express the speed and regularity with which the motions succeed each other from the one end of the rays to the other.' Dr. Browne frequently met with these animals to the north of the western islands (West Indies).



[Beröe ovata.]

β.

Species whose cilia are twice as long as the interstices. (Genus *Medea*, Eschscholtz.)

Example. *Beröe rufescens*

γ.

Species whose cilia are situated in two ambulacral ridges. (Genus *Pandora*, Eschscholtz.)

Example. *Beröe Flemingii*.

Cydippe.

Body regular, free, gelatinous, divided into eight sections, more or less distinct, by as many double longitudinal rows of vibratory cilia. An internal cavity, with a large buccal (?) aperture, whence issue, and are prolonged more or less below, a pair of long appendages, which are retractile, and also furnished with vibratory cilia.

Example. *Cydippe pileus, Medusa pileus*, Gmelin; *Beröe pileus*, Lamarck; *Pleurobrachia*, Fleming; *Eucharis*, Péron, who really established the genus; but Eschscholtz having transferred the last name to a genus of Ciliobranchians, De Blainville prefers following him, to avoid greater confusion. [Beroë, vol. iv., p. 317.]

Callianira.

See the article, vol. vi., p. 163.

Mnemia.

Body smooth, oval, elongated vertically, very much compressed on one side, and as if lobated on the other. Buccal opening between the prolongation of the sides: conical appendages on which the rows of vibratory cilia are ranged.

Example. *Mnemia heteroptera, Callianyra heteroptera* of Chamisso, thus described by MM. de Chamisso and Eisenhardt:—Body hyaline, cylindrico-tubular, dilated at one extremity, with a transverse mouth, into which it was impossible to penetrate. A large cestoid wing on each side, with vibratory cilia on its edges; six intermediate smaller wings, of which the four inferior (buccal) are lanceolated, ciliated on the edges, and attached to the base of the body; two superior cestoid wings uniting themselves to the two large lateral ones, which Péron, according to the describers, erroneously regarded as branchiæ. It is suggested that the two pairs of appendages of the mouth may be the analogues of the buccal appendages of the Lamellibranchiate Malacozoairians;—the two double bands on each side their branchiæ;—and then the question arises whether the Ciliograda might not be placed under this type and form, a particular class, but little removed from the *Biphores* [Salpacea], and forming a passage still more marked towards the Actinozoairians. The cilia, which have some analogy with those on the edge of the mantle of the Lamellibranchians, are said to be only coloured by the decomposition of light between their borders.

Calymma.

See the article, vol. vi., p. 173.

Axiotima.

Body a little elevated, a little compressed, or subcircular, prolonged to the right and left into a sort of appendages, bearing the series of cilia towards their terminal half only, and up to their end. Mouth small, entirely deprived of labial appendages.

Example. *Axiotima Gaïdis*, Eschscholtz. Locality, South Seas, near the equator.

Eucharis (Eschscholtz).

Body oval, sufficiently elevated, slightly compressed, or subcircular, covered with papillæ, with the ambulacra of natatory cilia extended from the summit to the base. Mouth small, provided with two rather long pairs of appendages.

Example. *Eucharis Tiedmanni*, Eschscholtz. Locality, seas of Japan. This name had been employed, as we have seen, by Péron, to distinguish another genus of Ciliograda, and should not have been transferred: for in all such cases confusion must be the consequence. The student must now remember that the *Eucharis* of Péron and that of Eschscholtz represent two different generic forms.

Ocyröe.

Body gelatinous, transparent, vertical, cylindrical, provided above with two lateral musculo-membranous, bifid, thick, wide lobes, and with two fleshy ciliated rib-like elevations, with two other ciliated ribs upon the edges between the lobes: aperture provided with four ciliated arms.

Example. *Ocyröe crystallina*, Rang, who founded the genus. De Blainville thinks that it bears much resemblance to the last species of *Callianira*—*Callianira hexagona?*

Alcynöe.

Body gelatinous, transparent, vertical, cylindrical, with eight ciliated ribs, hidden in part under the vertical natatory lobes. Aperture provided with four ciliated appendages.

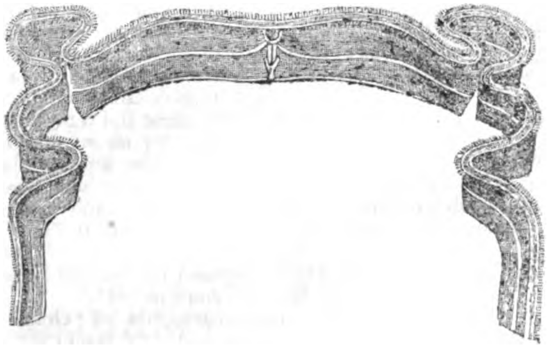
Example. *Alcynöe vermiculata*, Rang, who established the genus. Locality, coasts of Brazil.

Cestum.

Body gelatinous, free, regular, very short, but extended or prolonged on each side into a long riband-like appendage, bordered on each angle with a series of vibratory cilia, thus forming four ambulacra, two on each side. Mouth inferior and mesial, accompanied by a pair of long, ciliferous, retractile and simple appendages.

Example. *Cestum Veneris*, Lesueur.

Upon this singular genus De Blainville remarks, that it was established by Lesueur from an animal living in the Mediterranean Sea, and that he only knows it from the figure and description given by the author, unfortunately from an individual the extremities of whose lateral prolongations were truncated, and which nevertheless was a metre and a half wide. It is, adds De Blainville, evidently a very singular animal, but which may be doubtless considered as a very short Beröe with eight rows of cilia, pinched and drawn out as it were into an enormous riband of little thickness, and bearing upon each angle its ambulacra of cilia. In fact, it would appear, he continues, that the intestinal cavity, which is very short on account of the brevity of the body, is plunged laterally into the appendages; so that it must be believed that the opposite aperture escaped the notice of M. Lesueur, and that it is exactly opposed to the mouth, as in the true Beröes. He further states, that M. Martens had observed a complete individual though of small size, and that M. Martens was positively sure that it is nothing but a true Beröe. This, M. de Blainville says, M. Martens told him when at Paris with the officers of the Russian expedition round the world; and he adds, that, unfortunately, the premature death of that naturalist has left room for fearing that we may be long without the reasons on which he grounded his views. Cuvier, who places the genus among the simple Acalephans, describes the lower band of cilia as being smaller and less numerous, and the mouth as being in the middle of that border, and forming a large aperture which opens into a stomach pierced across the breadth of the riband, and leads to a very small vent. Two vessels, he adds, are given off from the extremity, near the vent, which run round the extremities of the riband. Two sacs open at the sides of the mouth: these are probably the ovaries. Cuvier concludes by comparing the animal to a Callianira with two sides, and whose wings are excessively prolonged; and he gives the length, or rather the breadth, at more than five feet, and the height at two inches. He further observes, that it is rarely found entire; and that the *Lemnisque* of Quoy and Gaimard (Freycinet's Voyage) is probably a fragment of Cestum. Lamarck places it, together with Callianira and Beröe, among the *Anomalous Radiaria*.



[Cestum Veneris.]

CIMABUE, GIOVANNI, was born at Florence, in the year 1240, of a noble family. During his youth he was sent by his father to study letters at the convent of Santa Maria Novella. When some Greek artists came to ornament the convent church with paintings, he abandoned studies to which he was little inclined, and devoted his attention to watching them; and he was ultimately permitted to assist them. Having acquired more knowledge than his instructors possessed, he became noted as one of the best painters of the day, and executed many works for religious persons and communities. His fame having spread abroad, he was invited to adorn the church of St. Francis at Assisi. He painted part of the walls in concert with certain Greek painters; but having far surpassed his assistants, his courage and ambition increased, and he went on with the work alone. He was recalled to Florence by private affairs, and obliged to leave his work uncompleted. It was afterwards finished by Giotto. After his return to Florence, among other pictures he painted a Madonna for the church of Santa Maria Novella, which was of a size so unusual at that time, and was considered so novel and splendid, that it was carried to the church in procession; and according to the tradition, when Charles of Anjou visited the church, multitudes who had not yet obtained a sight of the picture accompanied him with such rejoicing and festivity, that the street was afterwards called Borgo Allegri—literally, 'Merry Borough. Cimabue was engaged as an architect, in conjunction with Arnolfo Lapi, to build the church of Santa Maria del Fiore; but he died shortly after, in the year 1300.

Previously to the time of Cimabue, painting had sunk to a merely mechanical occupation, and was chiefly in the hands of Greeks, who worked after certain fixed patterns, each blindly copying his predecessor. Cimabue's right to be considered as the restorer of the art has been warmly urged, and as warmly contested. It appears probable that a reaction had taken place, and that contemporary or even preceding artists had shown an inclination to abandon the mechanical dryness of the modern Greek artificers, when Cimabue took up the profession. The ardour of his disposition however, and perhaps his rank in society, induced him to venture upon the most notable deviations from the cramped style of the period; and the revival of the art would probably have been delayed some time longer, had it not been for the impulse which it received through him. He put some life into the heads and into the action of his figures, abandoning the cold straight lines of his Greek instructors. He is supposed to have been the first to recur, after a long interval, to the study of nature, and to have drawn from the living model, though but sparingly. Nor is it the least debt which painting owes to Cimabue, that he discovered and fostered the genius of Giotto.

He worked in fresco and distemper, oil painting being a later discovery. Some of his works still exist; the principal are in the church of Santa Maria Novella at Florence, and that of St. Francis at Assisi. (Vasari; Lanzi.)

CIMARO'SA, DOMENI'CO, one of the most celebrated composers of the Italian theatre, was born at Naples in 1754. To Aprile he was indebted for his first instructions in music, but he completed his studies under Durante, at the Conservatorio of Loretto. His general education was also of a superior kind, and he was not only esteemed for his professional ability, but for his well-informed mind and amiable temper. The first work that made him known was 'L'Italiana in Londra,' performed in 1779. But it is 'Il Matrimonio Segreto' which will transmit his name to posterity; for it must be acknowledged, that of his thirty operas, most of which were in their day the admiration of all amateurs, the last mentioned is the only one now ever performed, or likely to be again heard. When this was brought out at Vienna, it so delighted the emperor, Joseph II., that at its conclusion he invited the singers and band to a supper, then sent them back to the theatre, and the whole piece was repeated; the only instance on record of the *encore* of an entire opera. In 1787 Cimarosa was invited by the Empress Catherine to St. Petersburg, where he produced three operas. He returned to Naples, and having shown no little partiality for the French during their occupation of that city, very narrowly escaped the sanguinary proscription which disgraced the restoration of the old royal family. He died at Venice in 1801.

Cimarosa excelled most in comic opera, but his 'Orazi e Curiazi' proves that he could compose well in a different style. He is the link which unites the old and modern schools, his scores exhibiting an instrumentation much stronger than that of Paisiello, though inferior in vigour and richness to that of Mozart. The latter was, by many composers of his day, censured for the fulness of his accompaniments. Grétry, when asked by Napoleon the difference between Cimarosa and Mozart, replied, 'Cimarosa, Sire, placed the statue on the stage and the pedestal in the orchestra, but Mozart put the statue in the orchestra and the pedestal on the stage.'

CIMBEX, a genus of Hymenopterous insects of the section *Terebrantia*, sub-section *Securifera*, and family *Tenthredinidæ*.

The genus Cimbex, as it formerly stood, has been subdivided (principally by Dr. Leach) into the following subgenera: *Cimbex*, *Perga*, *Syzygonia*, *Trichiosoma*, *Clavellaria*, *Zarea*, *Abia*, and *Amasis*. All these subgenera have the antennæ short, and terminated by thickened joints, which are nearly of an oval form; the third joint of the antennæ is long, forming a knob: the superior wings have two marginal and three sub-marginal cells.

The antennæ of these insects generally present six distinct joints, of which the two basal joints are very short, and almost concealed by the hair on the head; the third is long, the fourth and fifth are of moderate length, and the sixth is elongate (or moderate), rounded at the apex, and tapers more or less towards the base; this last joint is, however, evidently composed of two or three joints consolidated. All the joints of the tarsi have a membranous pad attached to their under side, and protruding from their apex.

The genus Cimbex, as now restricted, may be known by the following characters: body slightly hairy; abdomen with the basal segment emarginate above (that is, it appears as if a semicircular piece had been removed); the space thus left unprotected by the horny covering filled up with a membrane.* Thighs of the four posterior legs of the males very thick, those of the females moderate. Tarsi of the males with a tooth-like projection on the under side of the basal segment.

This genus includes the largest species of the family Tenthredinidæ.

Cimbex Griffinii is about an inch in length, and when the wings are expanded its width is about one inch and three quarters. It is of a reddish-brown colour; the abdomen is yellow, and more or less clouded with brown towards the base; the antennæ and tarsi are yellow, the former is brighter towards the apex.

The larva, we have been informed, feeds upon the sallow, and is not uncommon in the neighbourhood of Cambridge. Mr. Stephens enumerates eight British species of this genus, some of which, however, it is thought, will eventually prove to be mere varieties.

CIMBRI, or KIMBRI, the name given by the Roman and Greek historians to a vast multitude of people who came from the northern parts of Germany at the same time as the Teutones, crossed the Rhine, and entered Gaul, where they joined the Ambrones, a Celtic tribe, and, after ravaging and plundering part of Gaul, went into Spain, where they were repulsed by the Celtiberi. (Livy, *Epitome* lxvii.) The Teutones and Ambrones then made an irruption into Italy, where they were defeated by Marius, 102 B.C. Part of the Cimbri, however, had gone into Helvetia, where they were joined by the Tigurini, an Helvetian tribe, with whom they crossed the Pennine Alps, and, after defeating the pro-consul Catulus, entered the plains of Lombardy, where they were defeated by Marius in the year after the Teutones and the Ambrones, 101 B.C. From that time little or no mention is made of the Cimbri in history, but tradition says that the remnant of them settled in the central valleys of Helvetia, and the inhabitants of the Waldstätten and of the Bernese Oberland are supposed to be their descendants. Old Scandinavian words are traced in the dialect of these mountaineers. Of the original residence of the Cimbri we know nothing certain. Strabo (vii. 291—4) places them north of the Elbe beyond the Chauci, and numbers them among the German tribes. Pomponius Mela (iii. 3) places the Cimbri and Teutones in the islands of the Baltic Sea. Pliny speaks of the promontory of the Cimbri; and the peninsula of Jutland has been called Chersonesus Cimbrica, without however it being proved that the Cimbri ever inhabited it. It is probable that the Cimbri who invaded Italy were composed of mixed tribes, both Teutonic and Celtic, for in their war with Marius, the description of their arms, and the name of their chief Bojorix, appear to designate them as Celtæ. (Mannert, *Geographie der Griechen und Römer*.)

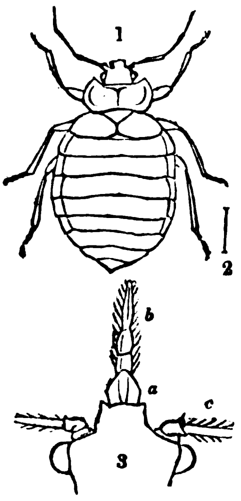
CIMEX. [CIMICIDÆ.]

---

* This structure is very remarkable, and is evidently to allow of a free movement of the abdomen in an upward direction.

CIMI'CIDÆ, a family of Hemipterous insects, the species of which may be distinguished by their having the rostrum short, and consisting of two or three joints only; the labrum also short, and without striæ; the eyes are moderate; the body is generally very much depressed. The principal genera are *Cimex, Aneurus, Aradus, Agramma, Tingis*, and *Dictyonota*, all of which are found in England. The genus *Cimex* is distinguished principally by the extreme slenderness of the two terminal joints of the antennæ, which are not thicker than a hair. The body is very much depressed: the thorax is transverse; antennæ four-jointed; basal joint very short, second long, the third of about equal length, the fourth rather shorter. Labrum rather long, somewhat pointed, and, when the proboscis is not in use, recurved under the head; proboscis three-jointed, and, when at rest, lies along the under side of the thorax, its apex being between the two fore-legs at their base.

There are said to be two or three species of this genus. We have however never had an opportunity of examining any but the common bug (*Cimex lectularius*), of which an account is given under the head Bug. We have here added an outline-drawing to show its structure; for although it is *too* common an insect, it is seldom examined except by the entomologist.



1, common bug (*Cimex lectularius*) magnified; 2, natural length of do.; 3, head of do. highly magnified; *a*, the labrum; *b*, the proboscis; *c*, base of the antennæ.

CIMOLITE, a hydrous silicate of alumina found in the island of Cimola. It occurs in amorphous earthy masses, the structure of which is rather slaty. Colour greyish-white. Fracture earthy, uneven. It is soft and opaque, and its specific gravity is 2·0.

It is used for the same purposes as fullers' earth.

CIMON (Κίμων), the name of two Athenians, one the father (Herod. vi. 34) and the other the son of Miltiades. The memory of the elder Cimon rests almost entirely on the fame of his son; scarcely any thing is known of him except that he was remarkably stupid. Cimon, the son of Miltiades and Hegesipyle, was born about 502 B.C. Miltiades died in prison, and Cimon had to pay the fine which had been imposed on his father. Without the aid of the opulent Callias, who is said to have assisted him, fifty talents would probably have made a large and inconvenient inroad on his patrimony.(Herod. vi. 136). The anecdotes which remain of Cimon's early youth are not creditable either to his morals or to his intellect. The worst excesses are laid to his charge. Although little confidence can be given to the details of these numerous reports, so much seems to be clear, that he did not do as others of his rank did, or as it was expected that the son of Miltiades would do. He even neglected what in Athens were usually deemed the essential branches of a liberal education. On the other hand, the stupidity which is ascribed to him at this period, and the reputation for which fixed on him his grandfather's nickname Coalemus (ὁ κοάλεμος, 'the idiot'), was probably nothing more than a natural reserve, combined with a certain inaptitude to social vivacity or oratorical display, which however may not have at all disqualified him for the services of active life. He seems to have excelled rather in doing, than in talking about doing. Aristides almost alone discerned in him the elements of a great character; and it is probably to his fostering charge and counsels that the glorious results which were afterwards developed are partly due.

Cimon's entrance into public life may be placed at the conquest of Eion, on the Strymon, B.C. 476. This town, which was very important to the Persians, was desperately defended by the garrison under the command of Boges, who at last, rather than surrender, raised a huge pile, placed on it his wife and children, and servants, and all his treasures, and after thowing his gold and silver into the Strymon, cast himself into the flames. (Herod. vii. 107; Thucyd. i. 98.) Cimon's next victory was at the island of Scyros, which he seized under the pretence that it had been guilty of piracy which called for punishment. He planted a colony of Athenians, and divided the land amongst them. (Thucyd. i. 98.) But Cimon's most important victory was at the Eurymedon in Pamphylia, B.C. 466, where he sunk or took 200 Persian ships, and carried away prodigious booty from their tents on the banks of the river. A squadron of Phœnician ships which was coming to the aid of the Persians was met by Cimon, and wholly destroyed. The Persians were still in possession of the coast of Thrace. That Cimon should feel peculiar interest in wresting those possessions from their power is easy to be explained: Olorus, the father of Hegesipyle, had been king of Thrace. (Herod. vi. 39.) Accordingly he sailed with a small force and dislodged them from his patrimony, and from a large extent of adjoining country. Twice he led a force to assist the Lacedæmonians, B.C. 464 and 461, at the siege of Ithome. The insulting manner in which the services of the Athenians were rejected by the Lacedæmonians (Thucyd. i. 101, 2) on the latter occasion, seems to have put the people in ill humour with all the friends of Sparta; and this may have had some effect in bringing about Cimon's exile. Towards the end of the same year (B.C. 461) in which they returned from Ithome, Cimon was banished for ten years by ostracism. (Clinton, *Fast. Hel.*, vol. i., p. 48.) In the year B.C. 457 there was a battle between the Lacedæmonians and Athenians, at Tanagra in Bœotia. Cimon presented himself to fight on the side of the Athenians, and took his stand among those of his own tribe. The council of 500 were consulted, and he was not allowed to remain: he left the army beseeching his friends to act like brave men, and to prove their attachment to their country by their deeds. The Athenians however were signally worsted; and this, with other defeats which they suffered during the exile of Cimon, seems to have led them to wish for his return. In the fifth year of his banishment he was recalled by a decree, of which Pericles himself was the mover. A five years' truce between the Athenians and Lacedæmonians was concluded through the intervention of Cimon B.C. 450. In the following year, 449, he was appointed to the command of a fleet of 200 vessels, which sailed to assist the Egyptian king Amyrtæus. He sent on a squadron of sixty galleys to the aid of Amyrtæus, and with the rest besieged Citium in Cyprus. Here he died, either from illness or from a wound. Just before he died he forbade his men to report his death until they arrived at Athens; and Plutarch preserves the remark of Phanodemus, that the army was as it were conducted by Cimon thirty days after he was dead. Though the Athenians were forced by want of provisions to raise the siege of Citium, they did not return home without a victory: they met with a fleet of Phœnician and Cilician ships near Salamis in Cyprus, and completely defeated them. They afterwards defeated a force on shore.

The slender private fortune to which Cimon succeeded had been considerably augmented by his Persian victories, and especially by the recovery of his patrimonial estates in Thrace. He did not use his acquisitions for personal aggrandizement: his munificence was not only fully equal to his means, but was in many respects judiciously dispensed: he preferred hospitality to luxury, and would rather provide a frugal entertainment for many, than a sumptuous banquet for a few. Many of the splendid improvements which he made in Athens were effected at his own cost. The walls from the city to the harbours of Piræus and Phalerum were commenced, and in great part executed at Cimon's expense. He changed the Academy from a barren uncultivated field to a shady and pleasant grove, and planted the Agora with plane trees. It is probable that his taste in these times as long as broad. This is distinguished from the last not only by the form of its leaves, which never taper to the point, but also by the pits at the under side of the leaves being bordered with inflected hairs; in *C. Condaminea* they are quite hairless. It is also allied to *C. rosea*, but that species has a smooth corolla and glandless leaves. In the quality of its bark, it is not distinguishable from *C. Condaminea*. Immense forests of this species exist in the province of S. Jaen de Bracamorros. It is the commonest of all the quinas in that part of Peru, and the most esteemed; in commerce it has the name of *Quina fina*.

[Cinchona scrobiculata.]

3. *C. lancifolia*. Leaves obovate-lanceolate, very smooth on each side, without glands; panicle large, brachiate; corolla silky on the outside; capsules oblong, smoothish, five times as long as broad. (*Syn.* C. nitida, R. and P.; officinalis, Ruiz; lanceolata, R. and P.; glabra, Ruiz; angustifolia, Ruiz.) Next to C. Condaminea this is accounted the most efficacious of all the species. It furnishes the orange-coloured bark, or the quina naranjanda of Santa Fé de Bogota, and is obviously different from the two former species, in its leaves being destitute of glands. Humboldt states that it prefers an inclement climate, on mountainous declivities, from 4000 to 9000 feet high, where the mean temperature is about that of Rome. In the Alpine forests of the upper limits of the zone inhabited by this species, the thermometer falls for hours as low as the freezing point. The plants are more rare than those of C. pubescens and magnifolia, always growing singly, and not increasing readily by the root. A kind of bark, bearing a high reputation at Cadiz, and called Calisaya, is referred to this species. It derives its name from the province where it grows, which is situated in the most southern part of Peru, in La Paz.

Another variety of this, according to Humboldt, a distinct species according to others, the Cinchona nitida of the 'Flora Peruviana,' is found only upon the coldest parts of the mountains of Peru, where it becomes a tree with a stem scarcely eight feet high. Its flowers are bright red, covered inside with a white down, and do not appear till May. Its bark, the Casc. hoja de Oliva, although of the finest quality, is never seen in commerce.

4. *C. pubescens*. Leaves ovate, very seldom subcordate, leathery, downy, or nearly smooth on the upper side, tomentose on the under side; panicle brachiate; corolla downy outside, the limb hairy inside; capsules ovate, oblong, ribbed externally, three times as long as broad. (*Syn.* C. cordifolia; ovata, R. and P.; pallescens, Ruiz; hirsuta, R. and P.) A most variable plant, yielding what is called yellow bark. It is found in the kingdom of New Grenada, in 4° N. lat., at heights between 5400 and 8650 feet; it has the name of *Quina amarilla*.

5. *C. purpurea*. Leaves broadly oval, somewhat wedge-shaped at the base, shortly cuspidate at the point, on the upper side smooth, on the under rather downy upon the principal veins; panicle large, brachiate; flowers somewhat corymbose; corolla slightly downy externally, its limb hairy inside; capsules cylindrical, becoming ovate-oblong, with longitudinal ribs, four times as long as broad. (*Syn.* C. morado.) A native of the Peruvian Andes, in the coldest and deepest part of the forests, about Chinchao, Pati, and elsewhere. It is also apparently one of the wild roots of Santa Fé de Bogota.

The very considerable size of the trees of this species, and its large membranous leaves, covered on the under side with prominent violet-coloured veins, are said by Pöppig to mark it readily. The bark, called *Casc. boba colorada*, is not in much esteem; but as it is readily collected, it can be sold at a low price, and is used for adulterating other sorts. According to Reichel, it is undoubtedly the Huamala bark of trade.

6. *C. macrocalyx*. Leaves ovate, roundish, hardly acute, quite smooth on both sides; their principal veins close together; panicles corymbose; corolla slightly downy externally, with the lobes hairy on the upper side; limb of the calyx smooth, bell-shaped, acutely five-toothed. A species distinguished by De Candolle by the above characters, but only known to him from specimens. It is found on the mountains of Peru: nothing is known of its sensible properties.

7. *C. Humboldtiana*. Leaves oval, rather obtuse, on the upper side shining, on the under between silky and downy; panicle brachiate, four-flowered; corolla silky on the outside, smooth in the throat, with its lobes shaggy inside at the point; capsules ovate, longitudinally ribbed, about twice as long as broad. (*Syn.* C. ovalifolia, Bonpl.) First described by Bonpland as identical with *C. ovalifolia* of the 'Flora Peruviana,' but afterwards recognized by him as distinct. It forms forests in the province of Cuenca, in Peru: in commerce it is called *Cascarilla peluda*, which signifies velvet-leaved quina. Its bark is not in much estimation; it is however a good deal collected for mixing with other sorts, and Bonpland suspects it to be of good quality

[Cinchona Humboldtiana.]

8. *C. magnifolia*. Leaves broadly oval, somewhat acuminate, smooth; principal veins of the under side shaggy at the edges; panicle brachiate; corollas silky externally; capsules oblong, tapering, seven times as long as broad.

(*Syn.* C. lutescens, grandifolia, oblongifolia.) According to Ruiz, Humboldt, and De Candolle, the *C. oblongifolia* of Mutis, which produces the red bark of Santa Fé, is identical with the *C. magnifolia*, or *Flor de Azahar* of the 'Flora Peruviana.' The former grows in 5° N. lat., at the height of from 3600 to 7800 feet above the sea, and is particularly common about Mariquita; the latter occurs in the hottest parts of the Andes of Peru, about 10° south of the line. *C. oblongifolia* of Santa Fé produces a bark which, although less efficacious than that of *C. Condaminea* and *lancifolia*, is nevertheless better than that of *C. pubescens*; but this is hardly reconcilable with Pöppig's statement, that the *C. magnifolia* has a woody, not very astringent bark, and is chiefly used for purposes of adulteration: he adds, that the bark-peelers do not even reckon it a fever bark, or *Cascarilla*, but name it simply *Corteza del Azahar*. This last-mentioned author describes the tree as very stately, with unusually large white flowers, diffusing a delicious odour like that of orange-blossoms; possibly the differences adverted to are the result of climate.

9. *C. macrocarpa.* Leaves elliptical, leathery, on the upper side perfectly smooth, on the under between hirsute and pubescent; panicle trichotomous; corollas with closely pressed down on the outside; its lobes hairy inside; capsules cylindrical, twice as long as broad. (*Syn.* C. ovalifolia, Mutis.) The white bark of Santa Fé. The tree grows between 3° and 6° N. lat., at heights between 4200 and 8400 feet: a variety of it, with leaves quite smooth on both sides, is common near Santa Martha.

10. *C. crassifolia.* Leaves oblong, rather blunt, tapered to the base, leathery, smooth on each side; when young shaggy in the axils of the veins; stipules membranous, grown together; corymbs terminal, trichotomous; branches two-edged, few-flowered; fruit oval-oblong, three times as long as broad, crowned by the calyx. Found about Quito and Loxa; distinguished from *C. macrocarpa* by its peculiar membranous stipules: nothing is known of its bark.

11. *C. dichotoma.* Leaves oblong-lanceolate, smooth, when first unfolding rather silky; peduncles terminal, dichotomous, in loose few-flowered corymbs; capsules linear, cylindrical, slender, fourteen times longer than broad. Found on the Andes of Peru, in groves near Pueblo-nuevo, in the district of Chicoplaya. Its bark is described as brown, intensely bitter, with a little acidity.

12. *C. acutifolia.* Leaves ovate, acute, smooth, the veins of their under side somewhat shaggy; panicle brachiate, stalked; corolla silky outside, woolly inside; capsules oblong, tapering to the base, four times as long as broad. A native of the lower woods of the Andes of Peru, in Chicoplaya. The bark is stated to be called *Casc. de hoja aguda*; it is moderately bitter.

13. *C. micrantha.* Leaves broadly oval, blunt, smooth, rather downy underneath at the base of the veins; panicle very large, brachiate, many-flowered; corollas densely silky; capsules oblong, three times as long as broad. (*Syn.* C. parviflora.) A species inhabiting the cold elevated parts of the Andes of Peru, especially about the village of San Antonio de Playa Grande; the inhabitants call its bark *Cascarilla fina.* The tree is of considerable circumference, flowers in February, and frequently yields eight to ten arrobas of dry bark, sometimes called *Cascarilla provinciana*, which differs from that of Huanuco by its decided whitish colour and greater roughness of the surface. It is thicker and more woody, the fracture is more fibrous, and the colour is of a bright cinnamon brown. A bark, called *Pata de Gallinazo*, from the numerous specimens of Graphis, a forked sort of Lichen, found on its surface, is yielded by this sort, as well as three others. Reichel considers the samples which Pöppig brought home as undoubtedly belonging to the Huanuco bark of commerce. Its taste, which is at first acid, becomes afterwards a powerful and permanent bitter.

14. *C. glandulifera.* Leaves ovate-lanceolate; on the upper side smooth and shining, with glands at the axils of the veins; on the under side shaggy, especially upon the principal veins; panicles somewhat corymbose; corolla velvety on the tube, woolly in the inside of the limb; capsules oblong, three times as long as broad. (*Syn.* C. glandulosa.) The flowers are three lines long, and of a pale rose colour This tree only inhabits the higher mountains of Peru, and is more scarce than many of the other kinds; its trunk is from 12 to 15 feet high, and its flowers, in the month of February, fill the forests with their perfume; on the colder parts of the mountains it becomes a bush, the greatest produce from which is five or six pounds of bark. It is considered, according to Pöppig, one of the finest sorts of Cinchona; he says that the Peruvians distinguish it by its blackish rind, which is only here and there interrupted by small shagreen spots when in a fresh state. The common people consider these blotches an integral part of the bark, and look upon it as the more valuable if beneath the larger spots there appears a black shining velvety substance dispersed in ovals of some lines broad; this is probably caused by some Byssus. The bark-gatherers hence call it *Cascarilla negrilla;* when broken, it exhibits a glossy, shining, almost rosiny fracture, of a ripe orange colour passing into a fiery brown. A variety of it, called *Casc. provinciana negrilla*, is obtained from the trees growing in warm valleys. According to Mr. Reichel, this bark is equal to the finest sort from Loxa, but it is not known in Europe, except in mixture with other kinds.

* *Corollas smooth externally.*

15. *C. caduciflora.* Leaves oval, smooth, erect, hairy in the axils of the leaves; panicle brachiate, with corymbose branches; corolla smooth, falling off very quickly; capsules oblong, four times as long as broad. (*Syn.* C. magnifolia, Humb.) Found near Jaen de Bracamorros, a hot damp country, where it is called *Cascarilla bora.* The tree is described by Bonpland as being above 100 feet high; its bark is not employed.

16. *C. rosea.* Leaves oval, tapering to the base, bluntly acuminate at the point, smooth on each side; panicles clustered, branches corymbose; corolla smooth on the outside, its limb downy above; capsules oblong, three times as long as broad. (*Syn.* C. fusca.) This occurs not unfrequently about Cuchero, where it forms a highly beautiful tree, which in its size and ramification may be justly compared with the white beech of Europe; in July it is covered with innumerable pale violet flowers, whence it has obtained the name of Palo de San Juan. Its bark is not collected, but Pöppig thinks it would be found to possess good qualities.

Cinchona Barks.—Whatever may be the botanical history of the different kinds of bark, on their arrival in Europe they are known by names which have reference rather to their physical appearance, or the place whence obtained, than to the botanical characters of the trees which furnish them. In England they are classed under three heads—pale, yellow, and red barks. Of each there are several varieties, which comprehend, however, various barks, not the produce of any of the genuine species of Cinchona above enumerated, but obtained from species of Exostemma, Buena, and Strychnos (according to Mr. Burchell). These last, called false or spurious cinchona barks, are all distinguished from the true cinchona barks by the absence of cinchonia, quinia, and aricina (or Cusco-cinchonia, a principle found in the Cusco or Arica bark, referred to the Cinchona rubiginosa, Bergen). Several of these spurious barks are employed in fever and other diseases, but they are chiefly used to adulterate the more valuable kinds of cinchonas. Even when there is no intermixture of these inferior sorts, a variableness in quality occurs in the bark of the same species, according to its place of growth. The finer kinds are known by experienced persons by a glance of the eye; but it is extremely difficult to indicate, by any description, the marks by which they are guided. All kinds arrive in Europe in the same package, either a chest or serone, which is formed of pieces of wood rudely fastened together, and covered with the hides of animals. They are afterwards sorted, and bring very different prices in the markets, according to the degree of estimation in which each kind is held. We shall describe the best kind only of each; but we must remark, that much prejudice exists on this point, and sometimes excellent kinds are rejected, while inferior sorts are prized. To meet these prejudices, the barkers employ various artifices, more or less injurious. The most useful classification of barks is that proposed by Geiger, which has reference to the relative proportions of their alkaloids:—1. Those in which cinchonia predominates: chiefly pale or brown barks.—2. Those in which quinia predominates, of which there is only one—the yellow bark of English commerce, called China regia vera, China calisaya.—3. Those in which cinchonia and quinia exist in nearly equal proportions, red barks, and the yellow bark of continental writers; the China of Carthagena of the French, China flava dura, quina amarilla. This last is also called orange bark (quina aurantiaca of Mutis), which is not the yellow bark of English commerce, though by some it is erroneously so considered; and hence the frequent error in the British pharmacopœias of referring yellow bark to the C. cordifolia (Mutis). Of the *pale* barks, three varieties are known in English commerce:—1. Crown or Loxa bark. 2. Gray, silver, or Huanuco bark. 3. Ash bark. These are always quilled, and never in flat pieces. The powder, which gives the name, varies from grey to fawn colour. The first variety, Loxa or crown bark, called also true Loxa bark, is obtained either exclusively from the C. Condaminea, or from it and C. scrobiculata. It occurs in pieces from 6 to 14 inches long, the quills varying in diameter from the fourth or even smaller part of an inch to nearly half an inch; the rolls are sometimes double, meeting at the centre: the diameter of the bark is from ¼ to 1½ line. The colour of the exterior is marked dark-grey, in some specimens verging to brown. A shining but peculiar appearance is observable upon it, owing to the thallus of the lichens spreading over it. This commonly alternates with the colours of other lichens, greyish-white, yellowish-white, bluish-white, so that the bark acquires an appearance as if it were painted. Numerous transverse cracks, often extending from one side of the bark to the other, with the edges a little raised, are seen, sometimes close to each other, sometimes more remote, especially in the larger pieces, in which also they rarely extend to the whole circumference of the piece. In the larger pieces, longitudinal cracks are observed, and between these warts or knots frequently arise, which give a very rough feel to such specimens. The Usnea florida, and some foliaceous lichens, such as Parmelia perforata (Ach.), often remain attached to it. The inner surface is smooth, except some delicate, irregularly longitudinal fibres: the colour is a cinnamon or darker brown. The fracture of the smaller quills is even, or slightly fibrous; that of the larger pieces more so, the fibres firm, but neither oblique nor vitreous, as in the yellow bark (China regia); but the outer circle presents a resinous aspect. The odour resembles that of tan. The taste at first is slightly astringent, and faintly acid; afterwards very astringent, somewhat bitter, but not acrid.

In respect to its chemical composition, this variety is commonly supposed to contain cinchonia (discovered in pale bark by Dr. Duncan, jun.) only; but this is a mistake, and it is most probable that the specimens which, when analyzed, yielded no quinia, were either very thin quills obtained from young branches or trees, or were specimens of Huanuco bark. Bucholz analyzed sixteen ounces of the Loxa bark of commerce, yet found no quinia, but some error is reasonably suspected: the other constituents were found to be

	Drachms.	Grains.
Fatty matter, with chlorophylle . .	1·	0
Bitter soft resin (Geiger thinks this contained quinia)	2·	0
Hard resin (red insoluble colouring matter)	12·	0
Tannin (with trace of acetic acid) . .	3·	0
Cinchonia	0·	28
Kinic acid	1·	30
Hard resin, with phyteumacolla . .	1·	49
Tannin, with chloride of lime . .	4·	25
Gum	5·	40
Kinate of lime	1·	40
Starch, a trace.		
Woody fibre.		

The cinchonia exists in combination with the kinic acid, in the form of kinate of cinchonia. A prejudice exists in favour of the thin quilled pieces, but they are not so well adapted to form extracts, &c., nor to be employed as medicine. Mutis many years ago stated that the thick pieces obtained from branches of middle-aged trees were the most efficacious; and the analysis of Von Santen (in Von Bergen's 'Versuch einer Monographie der China') confirms the correctness of this statement, as far as the relative amount of quinia yielded by barks of different ages is concerned. From 100 lbs. of Loxa bark, he obtained of quinia

	Ounces.
Thin selected quills . . .	1·042
Moderately thick pieces . . .	4·444
Selected thick heavy pieces, with rough cracked bark	11·104

2. Variety or Huanuco bark, termed from its colour silver or grey Cinchona, has been known in European commerce only since 1799. The majority of writers on the origin of the barks refer it to the *C. glandulifera*. (Ruiz and Pavo, *Fl. Peruv.*) As it is sent from Huanuco to Lima for shipment, it is also called Lima bark, though some apply the term Lima to a bark supposed to come from the *C. lancifolia* (Mutis). It is likewise called Havanna bark. We have the authority of Pöppig, as stated above, for considering it one of the finest sorts of Cinchona. The variety of it termed *Casc. provinciana negrilla* (the *Quinquina Huanuco noirâtre* of the French) is likewise stated by Reichel to be equal to the finest from Loxa, yet it is not known in Europe except in mixture with other kinds. The explanation of which is two-fold: first, that though the trade in this bark was at first very brisk, owing to its excellent quality, the subsequent shipments of it being very inferior, it fell into disrepute; and though it is now again pure and good, still it is necessary to introduce it as crown bark. Farther, as the French give the name Lima bark to another kind as above mentioned, probably the dark ash bark, the dark Ten (China Pseudo-Loxa), the false Loxa bark, confessedly a very bad bark, it has caused the genuine Lima bark to be little esteemed. Farther, as the Huanuco bark is in quills which are larger and coarser than the crown bark, the prejudice in favour of thin quills operates to the disadvantage of this very excellent sort.

The quills are from three to fifteen inches, generally from four to ten inches long, with a diameter from a few lines to one or even two inches. They are in single rolls, or double and enclosed rolls; the enclosed rolls exhibit spiral windings, and frequently traces of a sharp oblique incision of the knife. This incision is not observed in the case of any other kind, and it is probably made by the *cascarilleros* to facilitate the separation of the bark from the trunk of the tree. The diameter of the bark varies from ½ to 5 lines. The epidermis is seldom absent, but now and then portions of it have been rubbed off, and then the rusty surface of the liber is seen. The epidermis is a whitish-grey, but often covered with numerous lichens, chiefly Glyphis cicatricosa, Graphis duplicata, Porina granulata, Pyrenula discolor, mastoidea, Pupulo, Lecanora punicea, Parmelia perforata, Sticta aurata, and Usnea florida.

The character of the cracks is more variable than in Loxa bark, few extending to the whole circumference of the bark: in the young pieces the cracks are not so deep as in the older, in which also the edges are raised, giving a rough appearance to it. Some specimens also between the large and extensive cracks present spaces very slightly cracked, of a golden-straw or leaden-grey colour. Huanuco bark is distinguished by the brighter colour of its surface, the multitude of its small cracks, and the sharp oblique incisions above mentioned, from the yellow or Calisaya bark (*Quina regia*), and the Loxa bark, to both of which it bears considerable resemblance. The inner surface is of a bright cinnamon, passing into an ochre-yellow or rusty hue, and is generally rough, and, especially in the thicker quills, fibrous, frequently with portions of the wood of the stem adhering to it. Though no satisfactory chemical analysis has been made of it, exhibiting its entire composition, yet the relative proportions of its alkaloids have been stated. It is the richest in Cinchonia of all the barks hitherto examined. Goebel, Kirst, and Von Santen say that it yields this alkaloid only. Michaelis maintains that two specimens analysed by him yielded, in addition, a little quinia. The quantity of cinchonia is very variable. Kirst and Goebel obtained from 1 pound 168 grains; Von Santen from nine different specimens examined by him, from 1 pound a quantity varying from 106¾ grains to 210 grains. The fracture of the bark is either fibrous or splintery; that of the outer portion resinous. The odour resembles that of clay. The taste acid, astringent, somewhat aromatic; then bitter, acrid, and enduring. The powder is a deep cinnamon-brown.

The third kind of pale bark, called ash, jaen, or by corruption ten-bark, is by Von Bergen referred to *C. ovata* (R. and P.), which he considers synonymous with the *C. pubescens* of Vahl. It is likewise called pale ten-bark to distinguish it from the dark ten-bark, or false Loxa bark.

The quills of this kind are always crooked, frequently also twisted. The epidermis is frequently absent; when present, it presents faint transverse cracks, the edges of which are somewhat raised, and a few longitudinal cracks or warts. The bark itself is of an ash-grey, whitish-grey, or light yellow colour, with brown or blackish spots. It has often a slightly shining aspect. The inner surface varies very much, sometimes smooth, sometimes with long fibres attached to it, sometimes splintery, of a cinnamon or dark brown colour. The fracture is sometimes even, sometimes slightly fibrous, with a faint external resinous circle. The odour is a little like tan, and pleasant. The taste slightly acid and moderately astringent, a pure but not disagreeable bitter. The accounts of its chemical composition differ much. Von Santen says it contains neither cinchonia nor quinia. Goebel and Kirst from 1 pound obtained no cinchonia, but 12 grains of quinia; while Michaelis says in two specimens examined by him, he found both quinia and cinchonia; of the former, even 80 grains; of the latter, 12. Notwithstanding this last statement, this is generally and justly regarded as a very bad sort of pale bark, and was chiefly used to adulterate the true Loxa bark.

The dark ten-bark or China pseudo-Loxa, occurs generally in thin or middle-sized, but seldom thick, quills. The surface exhibits transverse cracks and longitudinal wrinkles, which often form rings a line or more broad. The colour is milk-white, but covered with so many lichens as to have a dark appearance. The under surface is uneven, fibrous or splintery, the fibres often very long: the colour a rusty brown. The fracture is fibrous or splintery: it exhibits a resinous appearance only when cut. Smells strongly like tan. The taste at first enduringly acid, afterwards astringent. This bark is frequently purchased instead of the true Loxa bark, and is at present of frequent occurrence in the market. Bergen considers it to be produced by the *C. nitida* (R. and P.) and the *C. lancifolia:* these are perhaps only varieties the one of the other; but whencesoever obtained, it is very poor in alkaloids, 1 pound yielding only 9 grains of kinia and 12 of cinchonia. It is held to be one of the worst kinds of pale bark.

The lichens and epidermis should be scraped off all pale barks before they are reduced to powder: though they increase the bulk, they diminish the efficiency of the powder.

The yellow barks.—There are only three kinds; the yellow bark of English commerce, which by continental writers is called merely China regia, quina Calisaya (the quinquina royal, Gelbe Königschina), and the yellow or Carthagena bark of the continent comprehending two sorts:—1. China flava fibrosa, China de Carthagena fibrosa, the quina naranjada (of the natives). The quina de Santa Fé fibrosa, or quina de Carthagena lenosa (fibrosa), of the Spanish, quina de Carthagena amarella lenhosa (fibrosa) of the Portuguese, quinquina de Carthagene fibreux, ligneux, quinquina orange (of the French), holzige gelbe china, holzige Carthagenarinde (of the Germans). —2. China flava dura, china lutea, china de Carthagena dura, quina naranjada de Sta. Fé, quina aurantiaca, quina de Santa Fé, or quina de Carthagena dura (Spanish), quina de Cartagena amarilla dura (Portuguese), quinquina de Carthagene, or quinquina flava dura (French), harte gelbe china, harte Carthagenarinde. This is the orange bark of Mutis, which he says is obtained from C. lancifolia. Bergen and Goebel ascribe it to C. cordifolia (Mutis), which some deem synonymous with C. pubescens (Vahl), which species is therefore stated alone to yield the yellow bark; but this only applies to the yellow bark of the continent, for the source of the yellow bark of English commerce must be considered as yet undetermined. We shall limit our description to this last kind, as the best known in this country, and, at the same time, the most valuable. This occurs in two forms—quills and flat pieces; the quills were formerly most prized, but all well-informed persons now prefer the flat pieces as much richer in quinia. The quills are in general in single, seldom in double rolls, the diameter of which is mostly greater than even the largest quills of pale Loxa bark, being from ¼ to 1 inch, the length from 4 to 24, occasionally containing smaller quills inside the larger. The thickness of the bark varies from ⅛ to ¼ of an inch. The external surface is generally grayish brown, inclining to blackish, yellowish, or whitish, according to the kind of lichen by which it is beset. Few pieces are quite free from lichens; many specimens exhibit the waxyellow thallus of *Lepra flava* (Acha.), which appears as if fused upon it: this is a very characteristic mark, when present, of Calisaya bark. The quills seldom have the epidermis removed, which has both transverse and longitudinal cracks, which penetrate down to the bark itself, as their traces can be perceived upon it even when the epidermis has been removed. The transverse cracks frequently extend over the whole circumference of the piece, yet they are much interrupted by longitudinal cracks and furrows (this is more especially the case with the thinnest quills); but all of them have raised edges, resembling those of Loxa bark. Where the epidermis is wanting, the colour of the exposed part is of a cinnamon or rusty-brown hue. The colour of the inner surface varies according to the age of the bark. Generally it is a deep cinnamon, in recent barks verging to reddish; in older specimens it is paler, or a rusty-yellow. The transverse fracture is in the thinner quills smooth, in the larger fibrous, splintery, or vitreous: a resinous circle is under the epidermis. The longitudinal fracture is generally uneven, and delicately fibrous: this kind of bark is easily broken.

The flat yellow bark, or that in splints, occurs either with the epidermis, or divested of it (China regia nuda). Pieces retaining the epidermis are generally from one to five inches broad, generally quite flat, but sometimes slightly curved, from three to fifteen inches long, and from ¼ to ¾ of an inch thick. The characters of the epidermis correspond with that above described: the uncoated kind is most frequent, and occurs in splints from one to eight lines thick. The colour varies, but is generally a reddish or rusty-brown, and is nearly the same on both surfaces, so that in pieces which have become convex on the inner side, and concave on the outer, as often happens, it is difficult to determine which was the exterior: this is by far the best kind of yellow bark.

Adulteration of yellow bark is not very easy, but a kind of humalia-like bark used to be substituted for it.

The odour of genuine yellow bark is slightly that of tan. The taste is faintly acid, strongly but not unpleasantly bitter, aromatic, stimulating, and slightly astringent.

The analyses of uncoated yellow bark (Calisaya) by Pelletier and Caventou show its composition to be super-kinate of quinia, fatty matter, slightly soluble red colouring matter (red cinchonic acid), soluble red colouring matter (more than in gray bark), tannin, kinate of lime, lignin, amylum. When the uncoated kind is analyzed, some cinchonia is obtained. By a comparative analysis it is found that a pound of flat uncoated yellow bark yields nearly twice as much quinia as the quilled sort, a point of much importance to the preparers of that alkaloid. The Carthagena yellow barks both contain quinia, but in less quantity than the Calisaya bark; the hard Carthagena bark, in addition, yields cinchonia, but not the fibrous kind.

The *red* bark, of which one kind only is known in English trade, is generally referred to C. oblongifolia; though many doubts may be held on this head. Bergen is much more disposed to consider the C. oblongifolia as the source of the China nova, or Surinam bark, which is not officinal in Britain: this also is doubtful. Red bark has been known for 130 years, but was not much used in Europe till 1779. It occurs in quills and flat pieces, most frequently in the latter form. The quills are rolled singly, or doubly, from 4 to 15, but generally from 4 to 6 inches long, and from a few lines to 1 inch in diameter, the bark being from 1 to 4 lines thick. The figure of the flat pieces is variable, being generally very much broken, frequently with the epidermis entire; but this is often partially, seldom or never completely, absent. The length is generally from 4 to 24 inches, the thickness from ¼ to 1 inch, and the breadth 1 to 3 inches. The quills most frequently have the epidermis entire; some of them have a whitish yellow, or grayish white epidermis (interrupted by longitudinal and irregularly transverse cracks), a red hue shining through it. In fact, even in pieces with the epidermis entire, and covered by many lichens, the red hue is seen ever shining through—a characteristic mark of this kind of bark. The flat pieces have generally an amazing number of lichens upon them. In these pieces also what is called the rete mucosum is often very spongy. Warty bodies are found on some varieties. The inner surface is a reddish brown, varying in intensity. The fracture in thin quills is smooth, in those of a moderate thickness fibrous, and in thick quills and flat pieces fibrous and splintery: the epidermis, when penetrated by the resinous principle, exhibits a vitreous shining ring.

Pelletier and Caventou analyzed a specimen of the variety free from warts, and found it to contain

Superkinate of Quinia }
„ „ Cinchonia } in large quantity.
Slightly soluble red colouring matter, or red cinchonic acid.
Soluble red colouring matter (tannin).
Yellow colouring matter; fatty matter.
Kinate of lime. Woody fibre. Starch.

The relative proportions of quinia and cinchonia differ in different specimens; a pound of bark yielding in some instances 70 grains of cinchonia and 77 grains of sulphate of quinia, in others 184 grains of cinchonia and only 9 grains of sulphate of quinia.

The Humalies, or brown bark, is not known in English commerce; its source is not accurately determined.

Several inferior kinds, and others erroneously reputed to be cinchona barks, are met with, either accidentally or fraudulently mixed with or passed for the genuine; but they may be known by not possessing the characters of the best kinds as given above.

(Bergen, *Monographie der China; Fée, Essai sur les Cryptogames des Ecorces exotiques officinales;* Goebel, *Pharmaceutische Waarenkunde.*)

In estimating the action of cinchona bark on the human system, it deserves to be borne in mind that the resin gives it a stimulating power, the kinate of cinchonia or quinia a tonic power, and the tannin an astringent property. By the first of these it approaches the balsamic stimulants and tonics, by the second the mineral tonics, while by the third it approximates to rhatany and catechu. Notwithstanding these resemblances, its action in the aggregate is strictly peculiar, so much so that all attempts to procure a substitute for it, whether among exotic or indigenous plants, have been attended with little success. It appears to act directly upon the nerves, particularly those of organic life, but its influence is speedily extended to the vascular and muscular system.

A moderate dose of cinchona taken into the stomach, and repeated in three or four hours, is followed by increased force and frequency of the pulse, greater firmness and constriction of the arterial tunics, augmented heat of surface, a flow of perspiration, and a universally improved tone of the system. The digestive and assimilating processes are greatly expedited, and the individual feels himself fit for exertions from which he would have shrunk before. This stimulating action does not cause vertigo or unpleasant derangement of the function of the brain. The secretions of all the mucous membranes, however, are diminished, and in most persons the bowels become constipated, but occasionally an opposite state, or diarrhœa, is induced.

It is justly considered the most valuable tonic and febrifugal medicine we possess. The forms of administration are numerous. Powder is objectionable from its bulk, disagreeable taste, and difficult digestibility, owing to the quantity of woody fibre which it contains. Infusion is a good form, but does not possess all the virtues of the bark, which, however, are all taken up by the tincture: the spirit present in this last form is often an obstacle to its being given in a sufficient dose; it is therefore generally added to the infusion or decoction. Decoction, if the process be long continued, dissipates the volatile or aromatic portion, and diminishes its powers. The tincture is often formed by the addition of other substances, as in the compound tincture of bark, which is a valuable adjunct to other remedial means in weak subjects. Acids or ammonia are sometimes given along with it, according to the nature of the complaint.

The ease with which a small dose can be taken of the sulphates of quinia or cinchonia leads to the substitution of these preparations for that of the bark itself; and in many cases they are more eligible, but in others the want of the resinous and astringent principles renders these less proper. Perhaps the best and most convenient form, as it can be administered in a variety of ways, is one in which the bark is separated into its constituent parts, the woody fibre removed, and the other principles again united: this is called the aromatic kinate of kinia. It keeps well in all climates, is not bulky, and retains its efficacy for several years. For long voyages it is the best form into which bark can be put.

CINCHONACEÆ, a natural order of monopetalous exogens, with an inferior fruit, a regular corolla, seeds containing a small embryo in the midst of horny albumen, and opposite undivided leaves with stipules placed between their petioles. This brief character distinguishes a most extensive and important assemblage of plants, comprehending many of the most useful species we are acquainted with. The bark of the order is very generally tonic, aromatic, and febrifugal, and its energy is attested by the well-known use of that of Cinchona itself, to say nothing of the numerous other genera fit to be employed as substitutes for Jesuit's bark. The albumen of the seeds when roasted affords, in the case of coffee, a fragrant, stimulating, and agreeable principle; and the roots of many herbaceous kinds possess active emetic properties. True Ipecacuanha is the produce of Cephaelis Ipecacuanha, but many other cinchonaceous plants resemble it in their medicinal qualities, and are perhaps mixed with it in commerce. Cinchonaceæ are the Rubiaceæ of many botanists; but as it appears advisable to separate Rubia and its allies into a distinct order, on account of the absence of stipules, and for other reasons [STELLATÆ], it is necessary to alter the name of the remainder of the group; and as a type of the order, when circumscribed, Cinchona is unexceptionable.

CINCHONIA, a vegetable alkali contained in all the varieties of cinchona, but principally in the Cinchona lancifolia, or pale bark. In the year 1803 Dr. Duncan recognized the existence of a peculiar principle in bark, to which he attributed its antifebrile power. Gomès, in 1811, procured it in a separate state; but its alkaline properties were not discovered till 1820, when Pelletier and Caventou published their experiments upon it; (*An. de Ch. et de Ph.*, xv.) The method by which they obtained it was as follows: Four pounds of bruised pale bark were digested with heat in twelve pounds of alcohol, and this treatment was four times repeated; the spirituous tinctures were mixed, water added to the mixture, and the alcohol distilled. The turbid residue being filtered, it left upon the filter a reddish substance, which was washed with a very dilute solution of potash until it passed through colourless. The matter left in the filter, after being plentifully washed with distilled water, was of a greenish white colour, very fusible, soluble in alcohol, and crystallizable. This was cinchonia, containing however some fatty matter.

In order to purify it, it was dissolved in very dilute hydrochloric acid: a liquor of a golden yellow colour was obtained. The cinchonia was precipitated from the hydrochloric acid by magnesia, a cup of this earth being mixed with it, and the mixture digested in a gentle heat: this, when quite cold, was thrown upon a filter, and washed with water until it came through colourless. The precipitate, dried in a water bath, was treated three times with boiling alcohol, which dissolved the cinchonia; the solutions gave by evaporation crystals of a dirty white colour; these were re-dissolved in alcohol, and this solution yielded pure cinchonia by crystallization.

The properties of cinchonia are, that by slow evaporation of its alcoholic solution it is procured in slender prismatic needles; by rapid evaporation it is deposited in crystalline, translucent, colourless plates, which are not altered by exposure to the air. Cinchonia has a peculiar bitter taste, which is long in being developed, on account of its insolubility, which is so great that it requires 2800 times its weight of cold water for solution, but is rather more soluble in hot water. It is very soluble in alcohol, especially when heated, and when saturated at a boiling heat, crystals are formed on cooling; the alcoholic solution is extremely bitter. It is less soluble in æther than in alcohol, especially when cold: it does not fuse by heat till it begins to decompose. It has the alkaline property of restoring the colour of litmus, which has been reddened by an acid.

Cinchonia is composed of

20	equivalents of	carbon	6×20=120 or	78·43
11	„	hydrogen .	11	7·18
1	„	oxygen . .	8	5·23
1	„	azote . .	14	9·16
		Equivalent . .	153	100

It appears from the experiments of Pelletier and Caventou, that the cinchonia, in all the varieties of bark, is combined with kinic acid; and when this salt is treated with magnesia it is decomposed, the kinate of magnesia remaining dissolved, and the cinchonia being precipitated. Cinchonia is much more abundant in pale than in yellow bark, the latter containing much more quinia; the red bark contains both alkalis also, the quinia being in the larger quantity.

Various other methods of preparing cinchonia have been proposed: by boiling the bark in dilute sulphuric acid, adding lime, and thus precipitating cinchonia in mixture with lime and its sulphate, and dissolving the cinchonia by alcohol, and treating this solution with an acid, and an alkali, &c. (Berzelius, *Traité de Chimie*, v., 152.)

We shall mention the principal salts of cinchonia, premising that they are prepared by saturating the various acids with this base.

Sulphate of Cinchonia is prepared by dissolving the alkali to saturation in dilute sulphuric acid, and evaporating the solution till a pellicle forms; on cooling and standing the salt crystallizes. It is colourless; unalterable in the air at common temperatures; but when the temperature is raised, or the air is very dry, it becomes slightly opaque; it effloresces when exposed to a gentle heat. It is said to crystallize in rhombic octohedrons, which are rarely perfect.

Sulphate of cinchonia is soluble in about half its weight of water at 57°, and in equal weight of absolute alcohol at the same temperature: it is insoluble in æther. It is, like the other salts of cinchonia, decomposed by the alkalis, ammonia, potash, and soda, and by lime-water, all of which precipitate cinchonia. It is composed of

1 equivalent of sulphuric acid	40	or	15·09
1 „ cinchonia .	153		57·73
8 „ water . .	72		27·18
Equivalent . .	265		100

Disulphate of Cinchonia may be prepared by adding the alkali to the acid to supersaturation: this salt crystallizes in rhombic prisms, which are usually short. It is soluble in about 54 times its weight of water at the usual temperature, and more so in alcohol. It consists of

1 equivalent of sulphuric acid	40	or	11
2 „ cinchonia .	306		84
2 „ water . .	18		5
Equivalent . .	364		100

Nitrate of Cinchonia. Prepared by dissolving the alkali in very dilute acid; for it is decomposed by the concentrated acid. After evaporation a portion of the nitrate separates in globules, of an oleaginous appearance; if these be covered with water, they are, after some days, converted into groups of regular crystals.

Dihydrochlorate of Cinchonia. This salt is procured by adding the alkali to the dilute acid. It crystallizes in needles, which are very soluble in water. It is also soluble in alcohol, and but sparingly so in æther. It fuses below a boiling temperature. It is composed of

1 equivalent of hydrochloric acid .	37	or	10·8
2 „ cinchonia . . .	306		89·2
	343		100

According to Leibig, the neutral hydrochlorate obtained by exposing cinchonia to the action of hydrochloric acid gas, is composed of

1 equivalent of hydrochloric acid .	37	or	19·8
1 „ cinchonia . . .	150		80·2
	187		100

Kinate of Cinchonia. This, as already mentioned, is the salt which exists in the cinchona. When the solution is evaporated to the consistence of a syrup, silky acicular crystals are obtained, which are very soluble in water. For an account of some other salts of cinchonia, see Berzelius, vol. v., p. 164.

CINCINNATI, the largest town in Ohio, is situated in Hamilton county, 20 miles east of the south-western corner of the state, upon the north bank of the Ohio, and 20 miles above the mouth of the Great Miami. The town was founded in 1789, but did not become a place of any importance until after the beginning of the present century; its growth since that time has been very rapid. The population in 1800 was 750; in 1810, 2540; in 1820, 9642; in 1826, 16,230; in 1830, 24,831; and in 1831, 28,014. The rapidity of increase in the later periods is attributed to the opening of the Ohio State canals, by which the trade of the town has been greatly facilitated. With the exception of New Orleans, Cincinnati is now the largest town in the United States west of the Alleghany mountains. A great part of the trade of the town is carried on by means of steam-vessels. The number of these vessels plying on the western waters in 1831 was 198, of which 68 were built at Cincinnati. The casualties that attend this river-navigation are considerable. Of 348 steam-vessels built between 1811 and 1831, there were 87 lost by snags, burning, collision, and other accidents: during the same period, 63 steam-vessels were worn out. The registered and licensed tonnage belonging to Cincinnati at the end of 1834 amounted to 7905 tons, all of which was employed in internal navigation: of the above, 6880 tons were steam-vessels, 25 of which, of the burthen of 2459 tons, were built in 1834.

The town is situated partly on the first and partly on the second bank of the river, on a plain which occupies about four square miles, and is surrounded by a range of finely wooded hills. The height of the rising ground is not more than 50 feet from the surface of the plain.

Cincinnati is the seat of numerous manufacturing establishments; among which cotton and woollen mills, steam saw-mills, lead works, distilleries, and breweries are the most important. The Miami canal from the town to Dayton, a distance of 66 miles, has been open since the spring of 1829. A company was incorporated in 1832 for constructing a rail-road from Dayton to Sandusky on lake Erie, which, when completed, will afford communication between Cincinnati and the lake, a distance of 175 miles.

The town contained, in 1830, eighteen places of worship belonging to the episcopal church, Roman Catholics, Jews, Unitarians, Presbyterians, Methodists, Quakers, Baptists, and other denominations. The Lane Seminary, so called from the name of its earliest benefactors, who were merchants in New Orleans, stands on a small eminence called Walnut Hill, two miles from Cincinnati. Its object is principally the promotion of theological knowledge. The building is four stories, 100 feet long, and contains upwards of 100 apartments, besides a preparatory school, which is a separate building. A valuable farm is attached to this seminary, and the manual labour system is introduced: the number of students in 1832 was 88. The medical college of Ohio, founded in 1818, is situated in Cincinnati; it contained, in 1833, 110 students. A law school has recently been established in the town. There are four banking establishments, the aggregate of whose capitals amounts to five millions of dollars. The town also supports eighteen newspapers, four of which are published daily, four thrice a week, and ten weekly.

(Stuart's *Three Years in America; American Almanac and Companion; Papers laid before Congress.*)

CINCINNATI, ORDER OF, an association established at the termination of the revolutionary war by the officers of the American army, which, in reference to the transition made by most of them from the occupation of husbandry to that of arms, took its name from the Roman Cincinnatus. The society was called an 'order,' and an external badge was provided of a character similar to those worn by the knights and other privileged orders of Europe. It was moreover provided that the eldest son of every deceased member should also be a member, and that the privilege should be transmitted by descent for ever. This principle of perpetuating a distinction soon became the object of attack. Judge Burke, of South Carolina, endeavoured, in a pamphlet, to show that it contained the germ of a future privileged aristocracy, and that it should not be allowed to develope itself. The society was publicly censured by the governor of South Carolina in his address to the Assembly, and by the legislatures of three states, Massachusetts, Rhode Island, and Pennsylvania. A correspondence ensued between General Washington and Mr. Jefferson concerning the institution in 1784, and the latter expressed himself altogether opposed to the principle of hereditary descent. The public disapprobation did not run less strongly in the same direction. At a meeting of the society soon afterwards, in Philadelphia, the hereditary principle and the power of adopting honorary members were abolished; but the society, in all other respects, was preserved. According to Mr. Jefferson, General Washington used his influence at the meeting in Philadelphia for its suppression, and the society would probably have been dissolved but for the return of the envoy whom they had despatched to France for the purpose of providing badges for the order, and of inviting the French officers to become members. As they could not well retract, it was determined that the society should retain its existence, its meetings, and its charitable funds. The order was to be no longer hereditary; it was to be communicated to no new members; the general meeting, instead of being annual, was to be triennial only. The badges were never publicly worn in America, but it was wished that the Frenchmen who were enrolled in the order should wear them in their own country. In some of the states the society still exists, and the members hold, or until lately held, triennial meetings. In others it has been allowed silently to expire. That of Virginia met in 1822, and transferred its funds (15,000 dollars) to Washington College. (Tucker's *Life of Jefferson*, vol. i., pp. 184-8.)

CINCINNA'TUS, a celebrated Roman consul. Little is known of him previous to the difficulties of his son Caeso, who, for opposing the tribunes in the performance of their functions, and for ill treating an old ex-tribune, was to be tried by the Icilian law. Sureties however were bound for his appearance. In the mean time he went into voluntary exile, and, according to Livy, the sum in which the sureties were bound was exacted from Cincinnatus. In order to pay it, he was obliged to sell nearly all his estates, and afterwards to retire to a small farm on the banks of the Tiber, where he cultivated the ground with his own hands. Being subsequently chosen consul, the messengers sent to acquaint him with his election found him engaged in the labours of agriculture. It is said that Cincinnatus, on hearing the news which they brought, was less elated by the honour his country had paid him, than grieved for the prospects of his farm during his absence. In the year of his consulship he succeeded in restoring tranquillity to the city, and establishing a partial agreement with the tribunes: the senate wished to continue him in office, but he insisted on resigning it at the close of the year, when he retired to his farm and rural occupations. Soon afterwards (A.U.C. 297) he was chosen dictator, and again received the announcement of his new honour while employed in the cultivation of his field. Conducted into Rome amidst the acclamations of the people, he forthwith marched against the Æqui, and gained a signal victory, after which he entered the city in triumph. He procured the recall of his son Caeso from exile, and then abdicated the dictatorship on the 16th day after he had received it. He afterwards headed an army against the Volsci, and added another to his former victories. In the absence of military tribunes, he was subsequently created interrex for a short time. A second time he was chosen dictator. Cincinnatus was now more than eighty years of age, and nothing but the solicitations of the consuls and senate induced him to accept the office. In all the posts which he filled at different times, his virtue and probity, as well as his patriotism and military success, gained him general admiration. Niebuhr (vol. ii. p. 289) rejects the story of Cincinnatus paying the fine of Caeso, as a mere fiction, fabricated to account for the humble circumstances of so great a man. (Dionysius Halicarnassensis, x.; Livius, iii. 26, 30, 31, &c.; Cicero, *De Fin.*, ii. 4; Niebuhr's *Rome*, vol. ii. p. 286, &c., *Engl. transl.*)

CINCINNU'RUS. [Bird of Paradise.]

CINCLOSO'MA, a group of thrushes, characterized by Dr. Horsfield and Mr. Vigors. [Merulidæ.]

CINCLUS. [Dipper.]

CINNA, LU'CIUS CORNE'LIUS, a Roman patrician, who belonged to the party of Marius. In 86 B.C. he obtained the consulship with Octavius, who made a strenuous opposition to his proposal for recalling Marius and his party from banishment. A dispute followed between the consuls, which was attended with bloodshed. Cinna, unable to make head against his opponents in Rome, withdrew to Tibur, Præneste, and other neighbouring towns, to seek for aid. By thus leaving his post he resigned his office, and the senate took an early opportunity to appoint another consul, L. C. Merula, in his room. Cinna, now in concert with Marius, Carbo, and Sertorius, advanced to Rome, and laying siege to the city, the senate were forced to propose a treaty, which was at last concluded. Cinna was reinstated in the consulship, and Marius was re-admitted as a Roman citizen. Marius however refused to enter the city until the sentence of banishment was formally repealed. Accordingly an assembly of the people was held; but while the votes were taking, Marius entered Rome with armed men, and forthwith proceeded to take vengeance on his opponents. Sulla's house was destroyed, and every quarter of the city was the scene of robbery and murder. Octavius, the colleague of Cinna, with many senators, fell in the massacre. The partisans of Marius were as reckless as their leader. At last Cinna and Marius themselves became desirous of putting an end to these revolting proceedings, and among other measures they seized on the consulship together. Marius died at the age of 70 years, on the first day of his entering on the office Cinna continued the usurpation which he had begun, and chose for his colleague Valerius Flaccus, to whom he assigned the province of Asia.

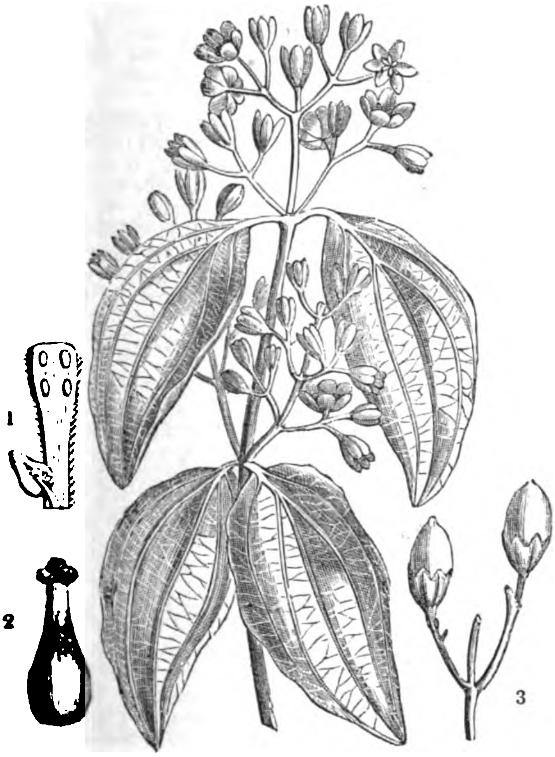
When Sulla had brought the Mithridatic war to a close, he contemplated returning to Italy, in order to punish his enemies. Previously however to setting sail, he sent the senate a statement of the services he had rendered and the wrongs he had suffered, at the same time threatening his enemies with his vengeance. The senate endeavoured to appease Sulla. They also attempted to moderate the fury of Cinna, but he persisted in prosecuting the war. He made himself consul, B.C. 83, with Papirius Carbo [Carbo], to whom he gave the command in Gaul. Cinna now prepared to oppose Sulla, and intended to meet him in Thessaly, by which route it was supposed he would return to Italy. The troops however were reluctant to embark, and an attempt to force them ended in a mutiny, in which Cinna was killed. C. Julius Cæsar married Cinna's daughter Cornelia. (Appian, *de Bell. Civ.*, i., 389—397; Livius, *Epit.* lxxix., lxxx., lxxxiii.; Florus, iii., 21; Velleius Paterculus, ii., 19—24; Dion Cassius *in Fragm.*; Plutarch's *Lives of Marius and Sulla*.)

Cornelius Cinna, a grandson of Pompey, headed a conspiracy against Augustus, who however generously pardoned him and made him consul. Their friendship remained afterwards unbroken.

CINNABAR. [Mercury.]

CINNAMO'MUM, an important genus of *Lauraceæ*, confined to the East Indies, and distinguished from the rest of its natural order by the following technical character:—Flowers hermaphrodite; abortive stamens perfect; anthers with four cells; limb of the perianth articulated; buds of the leaves incomplete; leaves evergreen, often approximated in pairs, three-ribbed or triple-ribbed. It contains several species, some of which yield cinnamon, and others cassia, two aromatic barks which appear to differ from each other in little, except in the degree in which the aromatic principle exists in them. Till lately it was understood that a Ceylon plant called *Laurus cinnamomum* yielded true cinnamon, and another, called *Laurus cassia*, produced the inferior cassia bark on the coast of Malabar; but, according to Nees von Esenbeck, at least two distinct species yield the cinnamon of the shops, and it is altogether uncertain which out of several yields cassia.

Cinnamon has been known to European nations from very high antiquity. The Greeks procured it, together with the name, as Herodotus (iii. 111) remarks, from the Phœnicians, who are by some supposed to have formed the name *Kinnamomon* from *Kagu-manis*, or *Kaschu manis*, two Malayan words signifying sweet wood (*Annals of Philosophy*, Oct. 1817); and cassia itself may have originated in the same word *Kaschu*, wood. That which is now chiefly consumed in England is the aromatic bark of a small tree found in the island of Ceylon. Its leaves are of an oblong figure, generally more or less heart-shaped at the base: of a thick leathery texture, very smooth and shining on the upper side, glaucous and beautifully marked with prominent netted veins on the under side; they are always blunt, and seldom even tapered to the point; they are nearly opposite on the branches, and are traversed by from three to five ribs, of which the lateral ones run in a curved direction from the base to the point. The flowers are greenish white, and appear in threes, collected in clusters, in small terminal panicles; they are composed of a downy calyx divided into six parts, and containing nine perfect stamens and nine others which are imperfect and resemble yellow triangular-stalked glands. Their pistil is a roundish one-celled body terminating gradually in a style with a white downy capitate triangular stigma. The fruit is an oval berry, not unlike an acorn, seated in the calyx, which is enlarged and converted into an angular six-toothed cup. The tree is supposed to produce a considerable number of varieties to which native names are given, but it is uncertain whether these are not, in part at least, distinct species. In addition to the aromatic oil contained in its bark, the root of the cinnamon tree yields camphor, the liber oil of cinnamon, the leaves oil of cloves, and the fruit a peculiar terebintaceous ethereal oil. When the branches are peeled the finest sticks of cinnamon are said to be obtained from the liber of the middle-sized branches, an inferior sort from the youngest shoots, and that which is produced by the thickest branches is considered of very little value. Of this plant, the *Cinnamomum Zeylanicum* of Nees von Esenbeck, the following is a figure —



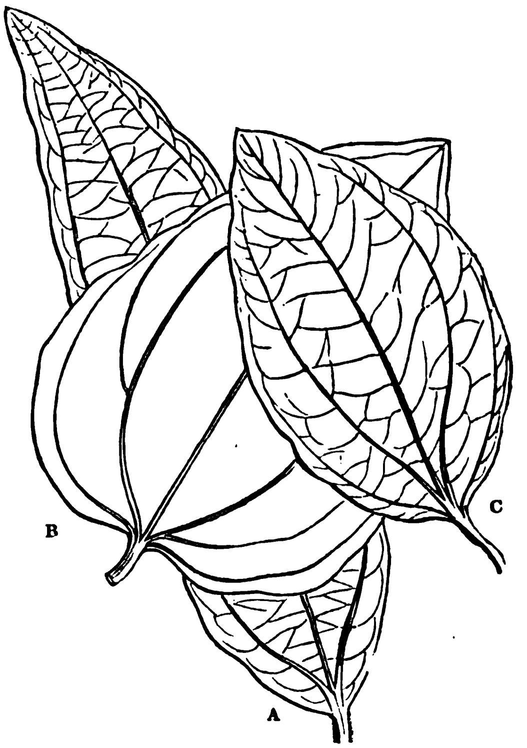
[Cinnamomum Zeylanicum.]

1, a perfect stamen, with one of the abortive stamens at its base; 2, a pistil; 3, ripe fruit.

It is said to require a rich sandy soil mixed with vegetable earth. Some degree of shade is necessary to the young plants, which therefore are not cultivated in open plains, but in spaces in the woods where a few large forest trees are left scattered about to shade them. In about six or seven years from the time they are sown, young cinnamon bushes are from four to six feet high; they are not however generally barked before the ninth year. The cinnamon peeling begins in May, at the end of the rains, and lasts till November; the operation of peeling consists in nothing more than slitting the bark longitudinally and then cutting it across, so that it can be readily turned back from the wood, and it is the more easy in consequence of the shoots which are cut for peeling not being more than three years old.

The cinnamon of China and Cochin China is believed to be the produce of a long-leaved species, called by Nees von Esenbeck *Cinnamomum aromaticum;* this plant, which is not uncommon in the hot-houses of Europe, has long been reputed the kind that yields cassia, but that opinion appears to be altogether unfounded. It is said to grow in the dry sandy districts, lying north-west of the town of Faifoe, between 15° and 16° N. lat. The leaves are very much larger than in the true cinnamon, they usually hang down from the stalks, have never more than three ribs, and never are in any degree cordate at the base; sometimes they are taper-pointed, sometimes blunt. A in the following figure is a leaf of this species; B and C are different forms of the leaf of the *Cinnamomum Zeylanicum.*

The aromatic fruits called *cassia buds* are also yielded by this species.



With regard to *Cassia lignea,* or *Cassia bark,* it seems altogether uncertain what it is that yields it; whether it is some peculiar species, as it has long been supposed to be, or inferior samples of cinnamon gathered in unfavourable seasons, or from trees growing in bad situations. The differences in cassia bark are of such a nature as to render the last the most probable conjecture; it possesses less aromatic oil, a circumstance likely to occur to trees in unfavourable situations; and in proportion as the oil disappears there is an increase in mucilaginous and resinous matter. But on the other hand there are so many inert or comparatively inert species of cinnamomum, that cassia may very well belong to one of them. There is C. dulce in China, obtusifolium, iners, Bazania, and others, any of which may possibly yield such a bark; the question is however one more of curiosity than real consequence. The only important thing about cassia was the supposing it to be furnished by what is really a most valuable species, and that error is now removed.

Cinnamon of the genuine Ceylon kind is cultivated in Guiana, the island of St. Vincent, the Cape de Verd, Brazil, the Isle of France, Pondicherry, Guadaloupe, and elsewhere, and it is said that plants obtained from Paris by the Pasha of Egypt have thriven when transported to Cairo. There is however no probability that the tree will succeed as an article of commerce in any country that has not the hot damp insular climate and bright light of Ceylon.

CINNAMON and CASSIA. There are many contradictory statements about cinnamon and cassia. In the following account we chiefly follow Fr. Ludwig Nees von Esenbeck, who has paid great attention to the subject. According to him, the finest or Ceylon cinnamon is procured from the three-year old branches of the Cinnamomum Zeylanicum (Blume), which is found native in the island of Ceylon only; the cultivation however has been extended to Java, and to South America. Though found in various parts of the island, it is most abundant in the south-west part, near Colombo, and yields the best cinnamon when growing in a sandy quartz soil. The time for stripping off the bark is from May to October. The bark, after being removed from the branches, is tied up in bundles for twenty-four hours, during which time a sort of fermentation takes place, which greatly facilitates the separation of the outer part of the bark from the cuticle and epidermis, which is very carefully scraped off the Ceylon cinnamon. It is then rolled up into quills, or pipes, about three feet in length; the thinner or smaller quills being surrounded by larger ones; a mark which always distinguishes cinnamon from cassia. It is then conveyed to Colombo, where it is sorted by government inspectors into three kinds, of which the two finest alone were allowed to be exported to Europe, while the third, or inferior kind, was reserved to be distilled, along with the broken pieces of the other two, for the purpose of obtaining the oil of cinnamon. The select cinnamon is formed into bales of about 92½ lbs. weight, containing some pepper or coffee, and wrapped in double cloths made of hemp, and not, as stated by some writers, of the cocoa tree.

This fine cinnamon occurs in pieces about forty inches in length, generally containing from six to eight rolls or quills in each, one within the other, of the thickness of vellum paper, of a dull golden yellow colour, smooth on both outer and inner surface. It is very fragrant, agreeably aromatic, taste pleasant, warm, aromatic, slightly astringent. Analyzed by Vauquelin, it yielded volatile oil, tannin in large quantity, an azotized colouring matter, a peculiar acid, mucilage, and feculum.

The root of the cinnamon tree yields a kind of camphor, and the leaves yield an oil which resembles oil of cloves, which it is often used to adulterate. This is quite distinct from the oil of cinnamon obtained from the bark. The ripe berries yield by decoction a solid volatile oil, similar to the oil of junipers. Cassia, according to Marshall and others, is the bark of the old branches and trunk of the Cinnamomum Zeylanicum already mentioned, while others assert that it is the bark of an entirely different species, viz., of the Cinnamomum Cassia (Nees Fratres, et Blume), a native of China, but cultivated in Java. This last view is much the most probable; for not only is no cassia exported from Ceylon (except the rejected or third sort of cinnamon, which is introduced into England incorrectly under that name), but almost all the cassia which reaches Europe comes from Canton. Re-agents produce very different effects both on the infusion and oil of these two barks, which is a rational ground for believing them to be obtained from different species [*].

Cassia is easily distinguished from cinnamon. The bales in which it arrives are much smaller, containing only from two to four pounds, bound together by portions of the bark of a tree. The quills are thicker, rolled once or twice only, and never contain thinner pieces within; the diameter of the bark is much thicker than that of cinnamon, and harder, the outer rind less carefully removed (large patches of the cuticle and epidermis often remaining upon it), the colour deeper, of a brownish fawn colour (that raised in Guiana is yellowish), with the odour of cinnamon, but fainter and less grateful, the taste more acridly aromatic, pungent, less sweet, at the same time more powerfully astringent, yet mucilaginous.

Cassia is often substituted for cinnamon, and it is also frequently adulterated with cassia lignea (which is the bark of a degenerate variety of the Cinnamomum Zeylanicum (Blume) growing in Malabar, Penang, and Silhet), with the bark of Cinnamomum Culitlawan, and with portions which by distillation have been deprived of their volatile oil.

Oil of cinnamon is obtained chiefly from the fragments which fall from the quills during the inspection and sorting at Colombo. These fragments are coarsely powdered, and after being immersed for forty-eight hours in sea-water, are distilled, when a milky fluid comes over, which separates into two parts, a light oil which floats, and a heavy one which sinks in the water. Eighty pounds weight of cinnamon yield about two ounces and a half of light oil, and five ounces and a half of heavy oil. About 100 gallons of oil of cinnamon are annually obtained at Colombo. As the oil which is met with in commerce is a mixture of these two, the specific gravity is variable, 1.035 to 1.090. In time a spontaneous separation takes place, and there are formed beautiful transparent crystals of a *stearopten* or cinnamon-camphor. Sometimes benzoic acid is formed. Oil of cassia is also obtained by distillation; at first it is whiter than oil of cinnamon, afterwards it becomes yellow, but never of such a fiery yellow as cinnamon-oil. The odour is agreeable, but not so delicate and cinnamon-like: taste, acrid, burning, but different from cinnamon. Specific gravity 1.0608: it reddens litmus paper. At a low temperature crystals show themselves, which disappear with an increase of heat. Some consider these a camphor, others benzoic acid. Benzoic acid unquestionably exists in this oil. Oil of cinnamon is adulterated with oil of cassia, with the oil of cassia-buds, with the oil of the cerasus lauro-cerasus, or cherry-laurel, and it is also said with oil of bitter-almonds, an exceedingly dangerous intermixture.

Cinnamon is an extremely valuable aromatic stimulant, and influences both the nervous and vascular system, especially of the stomach and intestines. It is of great utility in weakness of the digestive powers, unaccompanied with inflammatory action of the stomach; while in fluxes from atony of the intestines, its astringent properties, due to the tannin, render it a very useful medicine. Even in fevers of an asthenic type it has been advantageously joined with bark, and the compound cinnamon-powder is added to many medicines. Oil of cinnamon, given on sugar, is useful in cramps and other spasmodic diseases. Cassia has the same properties in less degree.

CINNAMOMIC ACID. When oil of cinnamon is exposed to oxygen gas, the gas is absorbed, and the result is the cinnamomic acid. This acid is colourless; it fuses at 248°, and boils at about 560° Fahrenheit. It distils without alteration, and, when heated, sublimes in scales. It is slightly soluble in cold water, but more so in hot: the solution gelatinizes on cooling. It is soluble in alcohol; and water decomposes the solution, precipitating the acid. The salts of cinnamomic acid are similar to the benzotes. It is composed of oxygen, hydrogen, and carbon.

CINNY'RIDÆ, a family of honey-sucking birds of brilliant plumage. [SOUI-MANGA.]

CINNYRIS. [SOUI-MANGA.]

CINQUE PORTS. It has been a subject of controversy, whether this association of the maritime towns on that part of the English coast which approaches nearest to the continent existed in any shape before the Norman conquest of England. In the course of the late municipal inquiry, the corporation of Romney (where the records relating to the Cinque Ports generally are kept) having refused all access to the documents in its possession, the commissioners appear to have been reduced, for historical information as to the chartered privileges of the association at large, to an examination of the printed charter of Charles II., the latest general one which they received, and in which a number of previous charters, from Edward I. downwards, are set forth. This document, in the original Latin, was published in a small volume at Cambridge in 1675, under the title of *Magna et Antiqua Charta Quinque Portuum, &c.*; and in 1728 it appeared in folio, with a translation and a very full and instructive comment, written fifty years before by Mr. Jeake, long an inhabitant of one of the Cinque Ports in question. This latter book is deemed of so good authority, that the municipal commissioners, in default of original documents, have confidently availed themselves of it.

It is stated by Jeake, that in one of the records of the town of Rye is a memorandum that 'the five ports were enfranchised in the time of King Edward the Confessor;' the five ports here intended, the original *Cinque Ports* of the Normans, being the towns of Sandwich, Dover, Hythe, and Romney, on the coast of Kent, and Hastings on that of Sussex. But a stronger presumption that all or some of these towns enjoyed peculiar privileges before the Conquest, arises from the fact, that the first charter of Edward I., the earliest set forth in Charles II.'s charter, in confirming all previous liberties, expressly heads the series of kings by whom they had been granted with the name of Edward the Confessor. Only three of these five ports being mentioned in the Domesday survey, viz. Sandwich, Dover, and Romney, Lord Coke thence infers that at first the privileged ports were these three only. These, it appears from that survey, on consideration of certain services to be performed by their shipping at sea, &c., were exonerated from such contributions and burdens as other towns were generally charged with; and these, it is reasonably thought, might have been enfranchised by the Confessor at one and the same time.

Though some part of the municipal constitution of the individual ports may be anterior to the Norman invasion, yet the organization of the general body, as it has existed in later times, is plainly traceable to the policy of the Conqueror in securing, by every means, his communications with the continent. These ports and their members occupy exactly the tract of sea-coast of which, after the victory of Hastings, he showed most eagerness to possess himself, by sweeping along it with his army before he directed his march towards London; and the surrender into his hands of the castle of Dover, which is the centre of the Cinque Ports' jurisdiction, was one of the stipulations introduced into the famous oath which, in Edward's lifetime, the duke had extorted from Harold. To enable his government to wield the resources of this maritime district with the greater vigour and promptitude, he severed it wholly from the civil and military administrations of the counties of Kent and Sussex, erecting it into a kind of palatine jurisdiction, under a *gardien*, or *warden*, who had the seat of his administration at the castle of Dover, and exercised over the whole district the combined civil, military, and naval authority; uniting in his own hands all the various functions which, to use the terms most intelligible to modern readers, we may describe as those of a sheriff of a county at large, a custos rotulorum, a lord lieutenant, and an admiral of the coast.

---

[*] In the article Ceylon, p. 457, the amount of cinnamon exported is much overstated. A gentleman, well acquainted with the trade, informs us that up to 1833 the average annual exports were about 6000 bales, and since that time to the present, about 5000 bales.

To the five ports of the Conqueror's time were added, before the reign of Henry III., with equal privileges, what were called the *antient towns* of Winchelsea and Rye, lying on the Sussex coast, between Hastings and Romney. To each of these seven municipal towns, except Winchelsea, were attached one or more subordinate ports or towns, denominated *members* of the principal port.

The internal constitution of each port, as well as the Norman denominations of *jurats* and *barons*, which, in lieu of *aldermen* and *freemen*, have constantly prevailed in them all since William's time, concur to show the solidity of his plan for rendering this maritime line one of the grand outworks of the conquest. The earliest members of the municipal bodies established under these foreign denominations, at a time when the English municipalities in general were subjected to the most rigorous enslavement, were doubtless trading settlers from William's continental dominions; and the term *barons*, as applied to the cinque ports' representatives, which in the later periods of English parliamentary history has usually been considered as simply synonymous with *burgesses*, did, before the several elements of the Commons' House coalesced into one homogeneous body, imply a political as well as a municipal superiority.

Until the time of Henry VII. the crown appears to have had no permanent navy: the Cinque Ports constantly furnished nearly all the shipping required for the purposes of the state, and their assistance to the king's ships continued long after that time. When ships were wanted, the king issued his summons to the ports to provide their quota. In the time of Edward I. the number they were bound to provide was fifty-seven, fully equipped, at their own cost: the period of gratuitous service was limited to fifteen days. The summons in Edward III.'s time seems to have apportioned the ships among the ports and their members: some of the members had to provide one ship; and in some cases two members had to provide one between them. It is in consideration for these services that, in the preambles of the existing charters, the peculiar privileges and exemptions of the ports are stated to have been granted. These towns, owing to various causes, have long since lost their antient importance. The physical changes that have taken place in the course of ages upon the coast-line may have had some effect. Rye and Romney, once standing on the shore, are now at some distance from it. Sandwich is only accessible for small vessels*; and the antient site of Folkestone, one of the members of Dover, has been almost wholly washed away. But the complete organization of a permanent navy involved the extinction of that description of service on the part of these ports, in consideration of which their privileges were avowedly granted; and their inferiority as ports, and their distance from all the great seats of English manufactures, sufficiently account for their present commercial insignificance. All these circumstances however have not prevented them from sustaining, until the recent measures of general reform, no inconsiderable political part.

Each of the five original ports returned two *barons* to parliament, as early as the 18th of Edward I.; Seaford, a corporate member of Hastings, sent as early as the 26th of the same reign; and the two antient towns, Rye and Winchelsea, sent as early as the 42nd of Edward III. The peculiar nature of the relation between the Cinque Ports and the crown must have given the latter, from the commencement, a very powerful influence in their internal transactions; and, in later times, when the parliamentary relations of the municipal towns came to be the grand object of solicitude to the royal prerogative, these municipalities imbibed an ample share of the prevalent municipal as well as political corruption. In the 20th of Charles II. the first open blow was struck by the crown at the liberties of the Ports in general, in the provision of Charles's charter of that year, by which the elections of all their recorders and common clerks were made subject to the royal approbation. Subsequently, in 1685, all the general charters of the Ports, and most of the particular charters of each individual town, were, by the king's special command, delivered up to Colonel Strode, then constable of Dover Castle, and were never afterwards recovered.

The lord-warden is the general returning officer for all the ports, the writs at every general election being directed to him in the same manner as to sheriffs of counties, whereupon he issues his precept for the election to the proper officer of each port. Before the Revolution of 1688 the lord-wardens assumed the power and the right of nominating one, and sometimes both, of the members for each of the port-towns having parliamentary representation; but this practice was terminated by an act passed in the first year after the Revolution, entitled 'An Act to declare the Right and Freedom of Election of Members to serve in Parliament for the Cinque Ports.' After reciting that 'the election of members to serve in parliament ought to be free,' and that 'the late lord-wardens of the Cinque Ports have pretended unto, and claimed as of right, a power of nominating and recommending to each of the said cinque ports, the two antient towns, and their respective members, one person whom they ought to elect to serve as a baron or member of parliament for such respective port, &c., contrary to the antient usage, right and freedom of elections,' it enacts 'that all such nominations and recommendations were and are contrary to the laws and constitution of this realm, and for the future shall be so deemed and construed, and hereby are declared to have been, and are void, to all intents and purposes whatsoever, any pretence to the contrary notwithstanding.' The necessity for such an enactment proves how firmly the practice must have been established; but although this statute had the effect of taking away the privilege from the lord-warden, the result was, that the Treasury influence was now enabled to return both members.

As regards the original titles to freedom in the ports, it appears, not only from general analogy and from the uniform language of the charters, but from the terms of an antient custumal of the ports received as evidence in a case of *mandamus* against the corporation of Hastings in 1736 before Lord Hardwicke, that the right to, and mode of, obtaining a freedom in each of the ports was originally uniform. The antient titles to freedom as recited in this custumal were these:—1. By birth within the town and port, if the man's father was free at the time of his birth; 2. By a freehold tenement; 3. By purchase, redemption, or gift. But at the time of passing the late Reform Act, the title to the municipal freedom (and consequently to the parliamentary franchise), by virtue of a freehold, was totally obsolete in all the port towns except Dover. Freedom by birth was allowed to all the sons of freemen at Dover, Sandwich and Hythe: at the other ports the claim of the eldest son alone was admitted; and even this, in later times, had been very much narrowed. In general, it was become the practice to admit such persons only to freedom, by election or redemption, as were either advanced in years, or for some other reason were not likely to have legitimate offspring.

Poverty also, and its attendant aptitude to passive submission, were among the principal recommendations to such admission. A freedom of a Cinque Port town was always considered as entitling its possessor to a provision of some sort. Thus at every one of the Cinque Ports there was a large custom-house establishment, including, besides the ordinary servants and retainers, five or six riding officers, and a custom-house boat, the crew of which, though rarely sailors, were always freemen. At three or four of the towns were stationed custom-house cutters, nominally to cruise against smugglers, but really to make provision for the friends of the minister, the whole body of their officers being freemen. As the salaries of the superior officers were very considerable, they had usually, according to the amount of their profits, one, two, or three of the lower class of freemen quartered on them, who were called riders—a practice which was very general as to all the Cinque Ports. Another common mode of binding the lower class of freemen to their political good behaviour was, by lending them small sums of money on bond; which, so long as they conducted themselves to the satisfaction of their superior, were never demanded, but which, if they proved refractory, were exacted with the utmost rigour.

---

* In fact Sandwich never could have been accessible to much larger vessels than it receives at present.

The history of the Cinque Ports in later times presents us with some of the most glaring and flagitious instances of the sacrifice of the local well-being of the community to the interests of the various descriptions of traders in political corruption. Down to the period of the late general reform, this municipal depravation was most mischievously apparent in the composition of the local magistracies, contrasted as it was with the ample powers of judicature which they possessed. For all purposes except one or two, each corporate town of the ports possessed all the jurisdiction and arrangements of a separate county, and the circuit judges held no assizes within their liberties; each town too had its distinct rate in the nature and for the purposes of a county rate, and its civil court of record; and most of the duties analogous to those of a sheriff of a county at large were exercised separately and exclusively in each of the port towns. According to the originally uniform Norman constitution of the ports, the number of jurats in each corporation ought always to have been twelve, besides the presiding officer, each of whom was, *ex officio*, a judge both of the civil and criminal court. The mayor or bailiff, and two other jurats, however, constituted a quorum. For the reasons indicated above, it became the practice in most of these towns to keep the number of jurats as low as possible, scarcely ever exceeding four or five.

From the body of jurats in each port, or corporate member, the mayor or bailiff was elected. Before the passing of the statute 9 Anne, c. 20, which enacts that officers having the return of members of parliament (which the head of the corporation has in each of the port towns) shall not be chosen for two successive years, the same person was usually continued in the office of mayor or bailiff for a great length of time, and sometimes in a manner for life; the agent or manager of the Treasury interest in each respective borough being almost uniformly appointed to that office. This statute however had here no considerable effect; it only occasioned the substitution in alternate years of some very near relative or mere dependent of the government agent.

In order to present a distinct view of the alterations effected in the Cinque Ports' jurisdictions by recent enactments, general and local, we give a table of the ports and their detached members (distinguishing among the latter the corporate from the non-corporate) as they existed at the commencement of the present century:

Ports.	Detached Members.
Hastings.	1. Corporate town of Pevensey; distant 12 miles from Hastings.
	2. Corporate town of Seaford; distant 22 miles.
	3. Part of Bexhill parish, in Pevensey Marsh; distant 8 miles.
	4. Small part of St. Leonard's parish, near Winchelsea; distant 9 miles.
	5. Beaksbourne parish, near Canterbury; distant 48 miles.
	6. Vill of Grange, or Grench, near Rochester; distant 50 miles.
Winchelsea.	
Rye.	1. Corporate town of Tenterden; distant 10 miles.
Romney.	1. Corporate town of Lydd; distant 3 miles.
	2. Denge-marsh; distant 5 miles.
	3. Orlestone; distant 10 miles.
Hythe.	
Dover.	1. Corporate town of Folkestone; distant 7 miles.
	2. Corporate town of Faversham; distant 25 miles.
	3. Parish of St. John, containing the town of Margate; distant 21 miles.
	4. Parish of St. Peter; distant 19 miles.
	5. Parish of Birchington; distant 20 miles.
	6. Parish of Ringwould; distant 5 miles.
Sandwich.	1. Corporate town of Fordwich; distant 10 miles.
	2. Corporate town of Deal; distant 6 miles.
	3. Vill of Ramsgate, including the town of that name; distant 4 miles.
	4. Vill of Sarr; distant 5 miles.
	5. Parish of Walmer; distant 8 miles.
	6. Parish of Brightlingsea; distant 40 miles.

It is probable that in very early times all the members were in some measure dependent on, or subject to, their respective ports; but in latter times there has been no connexion between any port and such of its members as have been incorporated, beyond that which exists among all the ports, excepting only the connexion between Sandwich and Deal. Each incorporated member has had within its liberty the same independent jurisdiction and municipal functions as the port itself. The unincorporated members have remained under the municipal jurisdiction of their respective ports; they have been within the jurisdiction of the criminal and civil courts, and of the magistrates and coroners of those ports; they have been summoned on the juries, and have contributed to the rates, in the nature of county rates, imposed by the justices of those ports. Yet none of the municipal franchises could be acquired in these members, nor had they any share in electing any of the officers of their respective ports; residence within them was not considered, for any corporate purpose, as residence within the port. The relation between Sandwich and Deal was peculiar. Deal was incorporated by William III., before which time it was exclusively under the jurisdiction of Sandwich. William's charter gave Deal a jurisdiction of its own; but as it did not interfere with the original jurisdiction of Sandwich, the latter retained a concurrent jurisdiction in Deal.

The jurisdiction of the Cinque Ports collectively extends along the coast, continuously, from Birchington, which is west of Margate, to Seaford in Sussex. But several of the corporate members are quite inland. Tenterden, in the centre of a rich agricultural district, has not even a river near it. Many of the unincorporated members are not only inland, but situated at great distances from their respective ports, some as far as forty to fifty miles. All the unincorporated members being exclusively under the jurisdiction of their own ports, each of those members was obliged to have recourse to the justices and coroner of its own port. Great inconvenience was experienced from this state of things, especially in those towns where the distance from the principal port was considerable.

Some part of the inconveniences above indicated was removed by the statute 51 Geo. III. c. 36, entitled 'An Act to facilitate the Execution of Justice within the Cinque Ports.' By this act three of the most remote unincorporated members, Beaksbourne and Grange (in Kent) belonging to Hastings, and Brightlingsea (in Essex) to Sandwich, were placed under the jurisdiction of the magistrates and coroners of the counties within which they are locally situated, and prisoners there were to be committed to the respective county gaols; but these members were to continue contributing to the liberty rate of their respective ports, excepting only for the maintenance of the gaols of those ports. As to the administration of justice, also, in the other unincorporated members, the act made some important alterations. By the act 54 Geo. III. c. 17, the precinct of Dover Castle was included in the jurisdiction of the town and port of Dover, from which it had formerly been distinct.

The Parliamentary Reform Act of 1832 worked a considerable revolution in the political relations of the Cinque Ports. Three of the towns, Seaford, Winchelsea, and Romney, being placed in Schedule A of that act, and Rye and Hythe in Schedule B, the number of Cinque Ports' representatives is thus reduced from sixteen to eight; Hastings, Dover, and Sandwich, still returning two members each, and Rye and Hythe one each. In the several constituencies of these five remaining parliamentary boroughs, besides the important change effected by the introduction of the household franchise, the new regulation of the parliamentary boundaries made very material alterations. Hastings and Dover have experienced the least change in this latter respect. In the case of Hastings, the two nearest of the detached members have simply been added to the 'home liberty' of the port itself, as before existing; and in that of Dover, the most populous part of one of the adjoining parishes has been added to the immediate liberty of the port. But in forming the new parliamentary borough of Rye, not only have the two 'antient towns' of Rye and Winchelsea been thrown together, but six surrounding agricultural parishes are also included within their common boundary. In like manner Folkestone, a corporate member of Dover, is now joined with Hythe, and five adjacent agricultural parishes, in composing the parliamentary borough of Hythe. And to the antient home liberty of Sandwich are added, for parliamentary purposes, the corporate town and parish of Deal, and the contiguous parish of Walmer.

The Municipal Reform Act has operated yet more decisively to break up the antient organization of the ports, and assimilate their internal arrangements to those of the improved English municipalities at large. Of the thirteen corporate port towns, four of the least considerable—Pevensey, Seaford, Winchelsea, and Fordwich—are not included in the Municipal Regulation Act. Of the nine which are included, Dover, Hastings, and Deal, are the most considerable; each of the three, being included in Schedule A of that act, is positively to have a commission of the peace in the mode prescribed for the municipalities in general in the body of the act. The six others—Hythe, Rye, Sandwich, Faversham, Folkestone, and Tenterden—are to have a commission of the peace only on petition of the municipal council, and grant by the crown.

The jurisdiction in capital cases, formerly possessed by the ports, is abolished by the act in common with all similar jurisdictions; and as regards the limits of the authority of the courts and magistrates of the ports, provision is made by section 134 of the same act.

Antiently there were several courts, exercising a general jurisdiction over all the ports and members. The Court of Shepway was the supreme court of the Cinque Ports. The lord warden presided in it, assisted by the mayors and bailiffs and a certain number of jurats summoned from each corporate town. The following offences seem to have been cognizable within the Ports' jurisdiction by this court only: treason, sedition, counterfeiting the king's coin or seal, and concealing treasure found. It was also a court of appeal from the judgments of the several local courts. This court has been so long obsolete that even the site of it is now unknown, except that it was most probably somewhere in that central part of the Ports' jurisdiction about which lies the division of the county of Kent, still denominated 'the lathe of Shepway.' Two other antient courts are still occasionally held, the Court of Brotherhood and the Court of Guestling. The name of the former seems to indicate its purpose to have been the regulating of the affairs of the fraternity or association of the ports in general. The latter court seems to have been only a modification of the former, practised on certain occasions. The Court of Brotherhood is composed of the mayors of the five ports and two antient towns and a certain number of jurats from each of them. The Court of Guestling consists of the same persons, with the addition of the mayors and bailiffs of all the corporate members, and a certain number of jurats from each of them. It is thought that the bodies forming this addition may originally have been merely *invited* by the Court of Brotherhood to give their assistance, and that hence the assembly may have received the name of Guestling. The chairman of the court is called the speaker, and the office is filled in rotation by the mayors of the five ports and two towns, each for one year. The speaker sends a letter every year to each of the corporations composing the two several courts, asking their opinion as to the expediency of holding either of them; and if a majority answer in the affirmative, the speaker convenes the court. One of the more important functions of the Court of Brotherhood antiently was the appointment of the two bailiffs whom the Cinque Ports had the privilege of sending to superintend their affairs at Yarmouth in Norfolk, and the examination of the conduct of those officers. The securing of certain facilities for carrying on the fishery during the herring season, granted to them by charter, and enforced by successive royal ordinances, seems to have been the main object of the residence of these officers of the Ports at Yarmouth, where also, together with the bailiff of that town, they had the keeping of the peace and the care of the prison during the fair, with the power of determining all disputes and complaints. As late as the reign of Elizabeth we find traces of the contentions which were constantly arising between the bailiff of Yarmouth and the bailiffs of the Ports residing there. In the Court of Brotherhood also the arrangements and regulations were made as to the apportioning of the service of ships to the crown. In these general courts, too, assessments were made upon all the ports and members for defraying the general expenses of the association; and in them all disputes between any of the ports, towns, or members were settled, and complaints of misconduct in any of their officers were inquired into and redressed. The necessity for proceedings of this kind no longer exists; and although these courts have been occasionally held of late years, such holding seems to have been mere matter of form, excepting only the Courts of Brotherhood and Guestling, held before each coronation, at which the arrangements have been made respecting the privilege of the *barons* of the ports to hold the canopy over the king's head on that occasion; another mark of the pre-eminence among the municipalities of England given to these towns by the princes of the Norman line.

Many of the privileges set forth in the general charters of the Ports are at this day of little value. The freedom from toll and dues seems to be recognised at several ports, though at others the claim to this exemption has not been allowed, at least without an extract from the charter certified by the corporation, and a certificate from the same body that the person claiming the exemption was a freeman. The only other privileges which the freemen of the Cinque Ports in general seem now to enjoy are, the exemption from serving on county juries by reason of property out of the liberties, and that from service in the militia; both which all the inhabitants of the Cinque Ports enjoy in common with them.

It remains to notice more particularly the nature of the lord warden's jurisdiction as now exercised. One important branch of a sheriff's jurisdiction is exercised by him over all the ports and members, viz., the execution of writs and the custody of debtors. All writs out of the superior courts are directed to the constable of Dover Castle, who is always the lord warden; upon which his warrant is made out, directed to and executed by an officer called the *bodar*. This officer, by a curious anomaly, has also the execution of writs out of the distant civil court at Hastings; and the necessity of having recourse to him has been a source of inconvenience and dissatisfaction to the latter town. The clerk of Dover Castle acts as under-sheriff. The constable's gaol for debtors is within Dover Castle; and by act 54 Geo. III., c. 97, their maintenance is provided for by an annual contribution of 300*l*., to be levied on the ports and members in proportions fixed by the act. The lord warden has power to diminish this sum if he think it more than sufficient, and to increase it again. The money is paid over to the registrar of the Cinque Ports, who, at the time of the framing of the report of the late municipal commissioners, was the same person as the clerk of Dover Castle.

The admiralty jurisdiction of the Cinque Ports, attached to the office of lord warden, is expressly reserved in that clause of the Municipal Reform Act which abolishes chartered admiralty jurisdictions in general. A branch of this jurisdiction appears in the court of Lodemanage, so called from the old English word *lodeman*, a *lead*-man or steerer, which is held for the licensing and regulating of pilots, by the lord warden and a number of commissioners, of whom the mayors of Dover and Sandwich are officially two. The lord warden seems antiently to have held a court of chancery in one of the churches at Dover, but it has long been obsolete.

For further details, see Jeake's *Charters of the Cinque Ports; the various Statutes relating to the Ports;* Oldfield's *Representative History of Great Britain; the Reports of the Commissioners for settling Parliamentary Boundaries under the Reform Act of* 1832; *those of the Commissioners in the late Municipal Inquiry; the Parliamentary Reform Act of* 1832; *the Municipal Regulation Act of* 1835; and for a fuller view of the various causes which successively operated to vitiate the early popular constitution of these in common with the other English municipalities, as also of the recent measures of general renovation, see BOROUGHS OF ENGLAND AND WALES.

CINQUEFOIL. [POTENTILLA.]

CINTRA, a town in the province of Estremadura in Portugal, in the comarca or district of Alemquer, 12 miles N.W. of Lisbon, on the slope of the Sierra de Cintra, which is the W. extremity of the great central chain that crosses the peninsula from the Ebro to the Atlantic, and of which the Sierra d'Estrella and the Monte Junto in Portugal form part. The neighbourhood of Cintra is celebrated for its mild climate and delightful quintas, or country-houses, the resort of the wealthy inhabitants of Lisbon during summer. The kings of Portugal have a palace at Cintra, with fine gardens ornamented by numerous fountains. Several halls of the palace are adorned with historical paintings. At a short distance to the west of Cintra is the pretty valley of Collares, which opens to the sea, and is also full of country residences. The country abounds with all kinds of fruit, especially oranges and lemons. Several convents are situated among the neighbouring hills. Cintra is known in contemporary history for the convention of 1808, by which, after the defeat of Junot by the English at Vimieira, the French agreed to evacuate Portugal. The town of Cintra has 4300 inhabitants. (Miñano, *Diccionario Geografico*, and Supplement to it.)

CI'ONUS, a genus of Coleopterous insects of the section Rhyncophora and family Curculionidæ.

Schoenherr (in his 'Synonymia Insectorum') links the present genus with the genera *Gymnœtron*, *Mecinus*, and *Nanodes*, under the head Cionides, which may be considered as a sub-family: we will therefore briefly state the characters of these genera under this head, first observing that the Cionides may be distinguished from allied groups by their having the antennæ nine or ten-jointed, five of which always compose the funiculus, or that portion between the basal joint and the club which terminates the antenna.

The characters of the genus Cionus are as follows:—Antennæ short, the two basal joints of the funiculus obconic, the remainder short and truncated at the apex; the club long and indistinctly jointed: rostrum elongate, curved, inserted in a groove beneath the thorax: thorax small; elytra nearly spherical, furnished with tufts of a velvet-like nature; femora very thick in the middle; tibiæ simple, truncated at the apex.

Four species of this genus are found in England; they live, both in their larva and imago states, upon plants, more especially those of the genera Scrophularia and Verbascum.

Cionus Verbasci is about one-sixth of an inch in length, and of a deep ash colour, approaching to black; the thorax is furnished on each side with a buff-coloured patch; the elytra have four longitudinal velvet-like bands, which are black, and interrupted with grey spots; there are two velvet-black spots on the suture, one near the base of the elytra and another near the apex; the former has a yellow spot joining it posteriorly, and the latter has a spot of the same colour before and behind.

These little insects are almost spherical: when touched or approached they apply their long proboscis close to the underside of the body (where there is a groove for its reception), and also the legs, and allow themselves to roll to the ground. Their larvæ, which are of a yellowish colour, and resemble small oblong masses of jelly, may be seen in the month of August on the leaves of the Verbascum, Thapsus, and some few other plants which they feed upon. When about to assume the pupa state they enclose themselves in a little brown spherical cocoon (less than an ordinary-sized pea) formed of a glutinous substance, which is attached to the leaves of a plant; in about a week or ten days after this, the perfect insect makes its appearance.

The genus *Gymnœtron* differs chiefly from *Cionus* in having the elytra somewhat ovate, sometimes depressed and not covering the apex of the abdomen, and the anterior tibiæ furnished with a minute hook at the apex. *Gymnœtron Beccabungœ* is the only species found in this country.

Mecinus may be distinguished from either of the two last mentioned by the rostrum being short and thick; the thorax subcylindrical, the elytra elongate, nearly cylindrical, and covering the body; the tibiæ are armed with a hook at the apex. Three species of this genus are found in England. Mecinus semi-cylindricus is about one-eighth of an inch in length, and of a blackish colour with ash-coloured pubescence.

The genus Nanodes has the antennæ rather long, the club large; rostrum elongate, slightly bent; thorax conical; elytra subovate and humped; the anterior tibiæ unarmed. No species of this genus have yet been found in this country. (See Schoenherr's *Synonymia Insectorum,—Genera et Species Curculionidum.*)

CIOTAT, LA, a town on the south coast of France, in the department of Bouches du Rhône, about ten miles S.E. of Marseille, in 43° 10′ N. lat., and 5° 36′ E. long.

This town is said to owe its origin to two or three towers which the Catalan fishermen, who frequented the coast, built about the year 1200 to protect themselves from the piratical vessels of Barbary: these led to the formation of a hamlet, dependent upon the neighbouring village of Ceireste or Cereste; the hamlet grew to be a town, containing a busy and enterprising population. Of the time when the harbour was first formed, nothing certain is known; the *new mole* was built A.D. 1645, and the place was walled in and forts were raised for its defence a few years afterwards. Expilly estimated the population, about the middle of the last century, at 10,000, but either this statement is inaccurate or the town has declined, for the last census (1832) gives only 4345 inhabitants for the town, or 5427 for the whole commune. The water in the town is brackish, but good water is brought from a short distance by women who gain a livelihood by it.

The neighbouring territory produces abundance of delicious fruits, excellent red and white muscadel wines, and oil; and the port is frequented by numerous vessels, which come for these productions. As there is a supply of wood in the neighbourhood, a number of small vessels are built here, not only for the merchants of the town, but also for those of Toulon and Marseille. The fishermen of this coast appear to be a peculiar race, distinguished by their good sense and their activity, and by various customs: they preserve their peculiarities by their practice of intermarrying among themselves. Their sports are athletic and suitable to the life which they lead. Their disputes are decided before a tribunal of four *prud'hommes* or magistrates, chosen from among the older members of their own class, who are distinguished for good sense and integrity: the brevity and cheapness of the proceedings which take place before them and the wisdom of their decisions render their institution valuable, and it is probably owing to this that it has been maintained during the changes which have occurred in the government of France.

On the opposite side of the little bay of the Mediterranean, on which La Ciotat stands, is a place called Tarento or Taurente which D'Anville considers to be the Ταυρόεις, Tauroeis (accusative Tauroenta, Cæs., *de Bell. Civ.*, ii. 4) of the Greeks and Romans. Roman remains yet exist on this spot, but they are more probably the remains of the villa of some wealthy Roman of the fourth century than of the public buildings of the town. Tauroeis was of Phocæan origin, and belonged to Massilia, now Marseille; it never appears to have been of any importance, and was probably only a fort (Castellum Massiliensium, Cæs.) for the protection of the coast. When Trebonius and D. Brutus, the lieutenants of Cæsar, besieged Massilia, the townsmen, after their first naval defeat by Brutus, effected a junction here with the vessels of Nasidius, whom Pompey had sent to their aid.

CIOULE or **SIOULE**, a river in France, in the mountainous district of Auvergne. It rises on the northern declivity of Mont Dor, and flows N. and N.E. until its junction with the Allier (one of the principal feeders of the Loire) below St. Pourçain. Its whole course is above 80 miles: it is not navigable in any part of its course, except for rafts. Expilly however says that its channel only needs to be cleared of the rocks and stones which now impede the navigation to render it a valuable outlet for the agricultural produce of the district through which it flows.

CIPHER is derived from the Arabic Sifr, which originally signifies 'empty, devoid of,' and is used as a substantive to denote the figure 0.

CIPOLIN. The cipolin from Rome is a green marble with white zones. It gives fire with steel, though with difficulty. One hundred parts of it contain 67·8 of carbonate of lime; 25 of quartz; 8 of schistus; 0·2 of iron besides the iron contained in the schistus. The cipolin from Autun consists of 83 parts carbonate of lime, 12 of green mica, and 1 of iron. (Nicholson's *Chemical Dictionary.*)

CIPRIA'NI, GIOVANNI BATISTA, descended from an antient family of Pistoia, was born at Florence in 1727. He received his first instructions from Heckford, an English artist. He afterwards studied under Gabbiani; or, according to Lanzi, he studied from a collection of drawings by Gabbiani, upon which he formed his style. In 1755 he came to England, and subsequently married an English lady of moderate fortune, by whom he had three children. He was one of the original members of the Royal Academy, and was presented with a silver cup by that body in return for the design for their diploma which he furnished. He died, much esteemed, Dec. 14, 1785, and was buried at Chelsea. Cipriani executed few paintings. Lanzi mentions two, in the Abbey of St. Michael on the Sea. He employed himself chiefly in drawing designs, of which Bartolozzi engraved a great number.

CIRCÆA, a genus of small herbaceous plants, found in woods and shady places. They have little whitish pink flowers having a tubular superior calyx, with a two-parted limb, two petals, two stamens, and an ovary with two cells, each of which contains one erect ovule. The genus constitutes the type of a section of Onagraceæ, in a reduced state. The species are commonly called Enchanter's Nightshade; but whatever supposed properties may have given rise to this name are purely imaginary.

CIR'CAETUS. [FALCONIDÆ.]

CIRCARS, NORTHERN, a large maritime province, lying between 15° and 20° N. lat., and between 80° and 86° E. long., and extending along the western side of the Bay of Bengal, from the Chilka lake on the north to the river Gondegama on the south. It has thus the district of Cuttack for its northern, and the Carnatic province for its southern boundary; on the east it has the Bay of Bengal, along a line of coast extending 470 miles; and on the west are Orissa, Gundwana, the dominions of the Rajah of Berar and of the Nizam, and the ceded Balaghaut districts. The average breadth of the province is about 80 miles, and its area about 38,000 English square miles. A continued range of mountains, impassable by carriages and difficult for horsemen, extends along the whole western frontier, from the Chilka lake on the north to the bank of the Godavery on the south. South of that river the province is separated from the Nizam's territory by a detached range of small hills. The province is watered by several small rivers, which rise among the hills forming the western frontier, and flow into the Bay of Bengal; it receives likewise the waters of the Godavery and Kistna rivers, whose mouths are within the province.

The Circars are politically divided into seven districts—Chicacole, Condapilly, Ellore, Ganjam, Guntoor, Rajamundry, and Vizagapatam. The climate of these districts exhibits a general uniformity. About the middle of June the westerly wind sets in, accompanied by moderate showers, until the end of August, when the harvest of the small grains is secured. From the beginning of September to the end of the following month the rain is more abundant; the wind is generally violent as November approaches, and then changes to the north-east, when the rice harvest, which constitutes the main dependence of the inhabitants through the greater part of the province, is housed. The season is then fair and pleasant, and at the vernal equinox the maize harvest commences. The season between the end of March and the setting in of the rains in the middle of June is hot, but the temperature is somewhat moderated by the sea breeze during the day. The soil towards the south is better than in the north. During the wars by which the Carnatic was formerly ravaged, so much of the country was suffered to be overrun with jungle as a protection from invasion, that it was always necessary to import some part of the grain needed by the inhabitants; but the security which the inhabitants have enjoyed during the last forty years has induced a larger cultivation, and they are no longer dependent upon external supplies. Fruits and garden vegetables are scarce. Sugar, cotton, and tobacco are produced; of the last, the quality of which is excellent, some part is exported. The forests upon the hills to the west contain abundance of teak wood of large growth. At the principal mouths of the Godavery ship-building is carried on, and vessels of 500 tons burthen have been constructed. From the nature of the country a great part of its trade is prosecuted in coasting vessels, the aggregate burthen of which exceeds 50,000 tons.

The district of Chicacole forms the largest portion of the recently created collectorate of Ganjam, including its capital. Exclusive of mountain streams, which are numerous during the rainy season, Chicacole is watered by four rivers, the mouths of which are at the towns of Chicacole, Calingapatam, Bimlipatam, and Vizagapatam: there are but few extensive plains in this district. The town of Chicacole, the Mohammedan name of which is Maphus Bunder, is in 18° 15′ N. lat. and 84° E. long. It is a large town, irregularly built on rising ground, forming the north bank of the Chicacole river, which rises in the mountains of Gundwana and joins the sea three miles below the town, where it is about 1750 feet broad. The centre of the town contains barracks, which are little used; and there are numerous mosques, the principal of which, a building of stone erected in the year 1051 of the Hegira (A.D. 1641), is held to be of considerable sanctity. Condapilly, called by the Mohammedans Mustaphanaghur, is separated from Ellore and Rajahmundry by the salt-water river Ooputair, which is navigable by boats as far as the Colair lake, the surplus waters of which it carries off to the sea; this it joins, after a winding course, between Samaldang and Gollapollam. The town of Condapilly, the capital of this district, stands in 16° 37′ N. lat. and 80° 33′ E. long.: this place was formerly a fortress of some strength, but the works are now in ruins. The district of Ellore, together with Condapilly last described, occupy the whole of the territory of the province comprehended between the Kistna and the Godavery. The town of Ellore, situated in 16° 43′ N. lat. and 81° 15′ E. long., is the residence of the collector of the Masulipatam district, of which collectorate this district forms a part. It is a large town; the houses not any of which exceed one story in height, are built with some regularity. Guntoor district lies between the Kistna and the Gondegama. The soil is very fertile. From the want of moisture during a great part of the year the cultivation of rice can be but little attended to, but the most luxuriant harvests of maize are raised. There are diamond mines in this district, but it is long since they have been productive. Guntoor, the chief town, is situated in 16° 17′ N. lat., and 80° 32′ E. long.; it is an extensive but irregularly built town, the walls of the houses being of mud, and the roofs of many thatched. It contains a great number of trees, and is divided into two portions by a large reservoir. The district of Rajahmundry lies on both sides of the Godavery, but principally on the north side of that river. The soil is fertile, particularly the island of Nagarum, a triangular space, comprehending an area of 500 square miles; which is formed by two great branches, into which the Godavery divides itself, thirty-five miles from the sea. Besides the two greater branches of the river by which it is enclosed, this island is intersected by five lesser branches; and the means of irrigation thus afforded, together with the slimy mould brought down by the greatest river of the Deccan, render the soil highly productive. The forests produce an abundance of teak timber; and in the plains, sugar, rice, ginger, turmeric, and various leguminous plants are raised. Cotton is also generally cultivated, but the quality is not good. The capital Rajahmundry is on the east bank of the Godavery, about 50 miles from its mouth, in 16° 59′ N. lat. and 81° 53′ E. long. The town is long but narrow, extending along an elevated bank adjoining the river. During the dry season the Godavery is here a clear blue stream, exhibiting many islands and shoals, and the banks on both sides are from twenty to thirty feet high, but in the rainy season the stream is a mile broad and very deep. Vizagapatam district, which lies to the north of Rajahmundry, is mountainous; a lofty ridge runs parallel to the sea-shore, and frequently within a very short distance of it, through nearly its whole extent; to the westward of this ridge is another chain; the intermediate space is a narrow and well-cultivated valley. The town of Vizagapatam lies on the coast in 17° 42′ N. lat., and 83° 24′ E. long., near to a promontory called the 'Dolphin's Nose,' a mountain about 1500 feet high. The town contains a considerable number of well-built houses; but the situation being unhealthy the place has been almost wholly deserted by Europeans, who have retired to the village of Waltier, about 3½ miles from the town, with which it communicates by an excellent road. There is a Hindu temple of great fame and antiquity at Semachillum, near Vizagapatam.

The northern Circars were among the earliest of the territorial possessions of the East India Company; they were granted in August, 1765, by the Mogul Shah Allum, 'by way of free gift, without the least participation of any person whatever in the same;' in November of the following year this grant was recognised by the Nizam or Soubahdar of the Deccan. The district of Guntoor was, at the date of the grant, held as a Jaghire for life by Bazaulet Jung, the Nizam's brother, by an agreement with whom the company rented that district, and it did not come into their actual possession until the death of Bazaulet Jung in 1788. For the whole province the company paid to the Nizam an annual *peshcush* or tribute of seven lacs of rupees (70,000*l.*), which was redeemed in 1823 by the payment of about 1,200,000*l.*, in virtue of which the Circars are now held in full sovereignty by the British. No census of the population of the province has ever been taken; an estimate was made in 1831, according to which the number of inhabitants was a little short of three millions; but it is evident that no great reliance can be placed upon the accuracy of a mere estimate. Mr. Sullivan, who was a resident for many years in the Madras presidency, stated rather loosely before the Committee of the House of Commons, in 1832, that according to his opinion the population of the Northern Circars was 'very little short of four or five millions of people.' The natives are represented as being a much finer class of men, both in appearance and in private character, than the natives of Bengal. The province is settled on the Zamindary system, and the old zamindars are said to be a remarkably fine and noble race of men: as regards the cultivators of the soil, they are very much on the footing of the Scottish chieftains of former days, the attachment between the two classes being continued through succeeding generations. With the exception of a few Mohammedans settled in the towns, the population of the Northern Circars is wholly Hindu. They are composed of two nations, the Telinga and the Ooria or Orissa, who speak and write different dialects, and have distinguishing customs and rites, although both adhere to the fundamental doctrines and discipline of the Hindu faith, and give undisputed preeminence to the Brahmins. The people have lived from time immemorial under the simple form of village government, and have preserved unaltered the names and limits of each of their villages, with its establishment of officers and servants, undisturbed by the changes which have transferred the sovereignty of the land from one set of rulers to another.

When the Circars came into possession of the English, a part of the lands were held by hereditary zamindars, and the remainder was under the immediate management of government officers: in those lands which were called *Havelee lands*, the public revenue was realized through the medium of renters to whom the rents due to government were leased for periods of years. The government has since assimilated the system throughout the province, by collecting different clusters of Havelee villages and forming them into zamindaries, which have been put up to public auction, the purchasers being entitled to hereditary possession upon payment of the revenue fixed in perpetuity upon the entire lands of the zamindary. Although these newly-created zamindars are considered by the government to be in all respects upon an equal footing with the old hereditary landholders, they are not so held by the community, but have received the distinctive title of Mootahdars, while the old zamindars are looked upon as the antient hereditary aristocracy of the country. Some of these have very large possessions, and pay a fixed annual tribute to the government of three lacs of rupees (30,000*l.*); nearly all of them reside on their estates, the management of which they retain in their own hands. The influence which they are thus enabled to exercise over the cultivators is very great, and instances have occurred where, in consequence of the tribute having fallen into arrear, the zamindary has been sold by the government, that the most serious rebellions have arisen, and the government has found it necessary, by private arrangements, to obtain back the estates from the purchasers, and restore them to the antient families. Of late, where any difficulty has occurred in paying the reserved rents, the government has taken temporary possession until its claims have been satisfied.

The revenue collected in the Northern Circars is said by Major Rennell to have amounted, in 1753, to about 43 lacs of rupees per annum. By a statement furnished by the East India Company in 1832, it appears that the revenue had then been augmented to 76,68,018 rupees (766,800*l.*), an augmentation of nearly 80*l.* per cent.

(Rennell's *Memoir of a Map of Hindustan*; Mill's *History of British India*; *Report of Committee of House of Commons in* 1832 *on the Affairs of India*.)

CIRCASSIA, or the country of the Circassians, is situated along the northern declivity of Mount Caucasus, and is now understood to comprehend the whole of this tract from the shores of the Black Sea to the vicinity of those of the Caspian, so that not only those portions which were formerly called the Great and Little Kabardia, but also the country of the Midszeges or Tchetchwenzes, who live towards the shores of the Caspian Sea, is included in it. [CAUCASUS.] The rivers Terek and Kooban, as far as their courses lie east and west, are considered as constituting the northern boundary; and the highest part of the Caucasian chain forms the southern.

The whole of this country is a succession of mountain-ridges, which branch off from the northern side of the Caucasus, and terminate near the rivers Terek and Kooban, and of valleys which lie between them. The mountain-ridges lower gradually, but with abrupt declivities as they proceed northward, and are commonly covered with wood in their lower portions. The highest of these collateral branches is that which detaches itself from Mount Elburz [CAUCASUS], runs north between 42° and 43° E. long., and terminates abruptly near 44° N. lat. with Mount Bechtan, which is 4320 feet high. This range is nearly destitute of trees, and contains a great number of warm and other springs, which are much visited, and known under the general name of Alexander's Baths. The valleys are very fertile, and generally of considerable width; but they contain numerous narrow passes, which render the access to them very difficult to an invading enemy, but tend to foster those predatory habits for which the inhabitants are notorious, and which render them the scourge of travellers and of their neighbours in the plain. The Russians, though acknowledged masters of the country, are not able to prevent their hostile excursions. Their generals and other officers have often been made prisoners, and have obtained their liberty only by paying large ransoms. To protect the adjacent plains, the Russian government has established a line of small fortifications along the banks of the Terek, Kooma, and Kooban; but 32,000 Cossacks, who are appointed to guard this line, find abundant opportunities of exercising their activity and military skill. The principal of these fortresses, Constantinogorskoë, lies south-west of Gheorghevsk, on the Podkooma, a branch of the Kooma, about 42° 40′ E. long., and 43° 50′ N. lat. Not far from it is the English missionary station of Karas, established in 1803 by the Scotch Society for Promoting Christianity, which being increased by a colony of Moravian brothers from Sarepta, now constitutes a village of 200 people. Its inhabitants are no less industrious in promoting agricultural and manufacturing industry, than in diffusing Christianity among the Circassians and Tartars; but hitherto they have made little progress.

There are no towns in Circassia, the habits of the people being opposed to the concentration of a great number of houses or of people on one spot. They live in small villages, the site of which is frequently changed. They cultivate the fertile soil of their valleys with little care; they raise millet and barley, and in some places also wheat and rye, with a small number of vegetables. The rearing of cattle is more attended to. Their horses are of a fine breed, and equally strong, swift, and beautiful; the people are proud of them, and, like the Bedouins, preserve the genealogies of their breed. The sheep, which are of the broad-tailed kind, are also much esteemed. The cattle are of a small kind. Milk, with millet, forms their principal food, and they make of it an inebriating beverage, the *koomiss*. As they are Mohammedans, they do not rear swine. Hunting is only followed by the noblemen, as a diversion.

The Circassians, or Cherkess, are the most numerous of the different nations that inhabit this country. They occupy the lower part of the mountains and valleys from the river Sundsha or Sunja on the east, to near the shores of the Black Sea. They consist of eleven tribes, independent of one another, and governed by their own hereditary princes and hereditary nobility. Their internal government resembles the feudal system. The whole population is estimated at 220,000. As the eastern portion of their country is called Kabardia, they are often called Kabardians; and it is certain that the Kabardians and Circassians belong to the same stock and speak the same language. To the east of the river Sunja live the Midszeges, also called Kistes and Tchetchenzes, who are said to be in number about 160,000. They differ entirely from the Circassians in language, but not much in character, being if possible still greater robbers. They seem to occupy the whole of the range to its very summits. The Ossetes, or, as they call themselves, Irones, occupy the higher part of the mountain range east of Mount Kazbeck, and consist of about 40,000 souls. The great road from Mozdock to Tifflis traverses their country. [CAUCASUS.] West of them are some smaller tribes, but the most western portion of the Caucasus is inhabited by the Avkhasas or Abasas, who occupy both the southern and the northern declivity, and are said to be about 240,000 in number. In their country is the small town of Anapa, which is fortified, has a small harbour, and about 3000 inhabitants. (Pallas; Reineggs.)

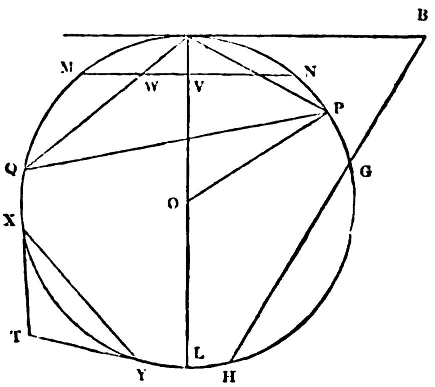
CIRCLE (*circulus*, a little circle, from *circus*, a ring), the figure formed by a point which revolves in a plane surface, and always preserves the same distance from a given point. The points of view under which this word might be considered are with reference, first, to its properties as a figure of geometry; second, to the history of the researches which were made for centuries, in order to discover the exact ratio of the circumference to the diameter; third, the effect of the properties of the circle upon several branches of mathematics. For the second, we refer to the word QUADRATURE; we shall give a few of the first, and a sketch of the third.

The word circle is sometimes used to denote the *circumference* or boundary line, sometimes the inclosed figure or area. Frequently a point *in* a circle means a point on the circumference; but a point *within* a circle always means a point in the interior. The *centre* is the point from which all the *radii* drawn to the curve are equal; a diameter is a double radius.



Draw a circle with a centre O, and let O A be any radius. Draw A B perpendicular to the radius, and M N also perpendicular to the radius. Take any points, P and Q, &c. Then among the most essential properties of the circle are the following:—

1. A B is a tangent to the circle.
2. M N is bisected (halved) by V.
3. The square on V N is equal to the rectangle (oblong), whose sides are A V and V L.
4. If any two chords (M N and A Q) cut in W, the rectangle, whose sides are M W and W N, is equal to that whose sides are Q W and W A.
5. The square on A B is equal to the rectangle whose sides are B G and B H, if the line B H be any line drawn through B, cutting the circle.
6. If Q move round the circle, and A and P remain fixed, the angle (opening) A Q P preserves the same magnitude throughout, namely, half of the angle A O P, and equal to the angle B A P.

These properties, with several others which are *visibly* true, are in the third book of Euclid. We name one or two others, the verification of which will be a test of correctness in drawing for those who know how to use the compass and ruler.

7. From any point T exterior to a circle, two tangents T X and T Y (of equal lengths) can be drawn. Let T be called the *pole* of X Y. Then if any number of poles be taken on the same straight line (which call the polar line), all their chords pass through the same point; which last point is interior to the circle if the polar line be altogether exterior; and exterior, if the polar line cut the circle.
8. If any hexagon, having no opposite sides parallel, be drawn in a circle, the three points of intersection made by lengthening the opposite sides must be in one straight line.

To find the circumference of a circle (with more than sufficient nearness for practical purposes), take the 113th part of 355 times the diameter (A L) or 3·14159 times the diameter. To find the area in *square* units, multiply the number of units in O A by itself, and take the 113th part of 355 times the result (or multiply by 3·14159). Given the arc A P, and the radius O A, to determine the angle A O P [see ANGLE]. And the same for the inverse question. To find the area of the sector A O P in square units, take half the product of the units in the radius and the arc A P. These are the principal questions which can be solved by a person unacquainted with trigonometry.

The influence of the properties of the circle upon abstract mathematical analysis has been so great, that an attempt to describe the manner in which the means of expression derived from this figure have been used would fill a volume. We can only here give such a description as will help the beginner in trigonometry to extend his notions of the symbols he uses. Originally the sine, cosine, &c. [TRIGONOMETRY] meant certain lines drawn in a circle, with reference to a given angle at the centre. Each angle therefore had a sine, &c. for every different length which the radius might be conceived to have. But this introducing an unnecessary complexity into formulæ, it was thought sufficient always to suppose the radius a unit, which was however always expressed. Thus in the first stage of the science we have this theorem: 'The sine of 30° is half the radius,' which in course of time took this form, 'The radius being 1, sin. 30° is ½.' This method amounted to defining the sine, &c. to be, not the lines which they originally stood for, but the numerical ratios of these lines to the radius. Thus the sine, cosine, &c. became abstract numbers. The next step was to make the angle itself an abstract number, in the manner which [ANGLE] we have called the *theoretical* method of measurement; that is, instead of measuring the angle by an arbitrarily chosen angle, such as a degree or a minute, the numerical ratio of the arc to the radius became the measure of the angle. One extension more completed the subject. Angles of more than four right angles were admitted, conceived to be made by the revolution of a point, which was considered as having made more revolutions than one. Thus any number represented some angle, and had its sine, cosine, &c. And the angles themselves being abstract numbers, and also their sines, &c., it followed that all the propositions of what was trigonometry, an application of geometry, became propositions of trigonometry, a part of pure arithmetic; retaining indeed the old names derived from geometry (names are never changed, witness the use of the term *square* in algebra), but based upon the notion of number, and the symbolic operations of algebra. Thus though it will always perhaps be thought desirable to lead the beginner through the gate of geometry, yet there must come a time, if he continue his studies to the higher branches, when he will consider a sine as a number, a function of a number; for instance, x being a number, the sine of the number x means the series

$$x - \frac{x^3}{2.3} + \frac{x^5}{2.3.4.5} - \&c. \textit{ ad inf.},$$

or any algebraical form which is equivalent to it.

This is the point to which works on trigonometry are rapidly tending; and seeing that the student must end, if he pursue his course, in such considerations, it is most desirable that he should begin in the same manner, to every extent which is consistent with not forcing abstractions upon him too rapidly.

The ratio of the diameter to the circumference of a circle is very near indeed to that of 113 to 355, which numbers this diagram will keep in memory,

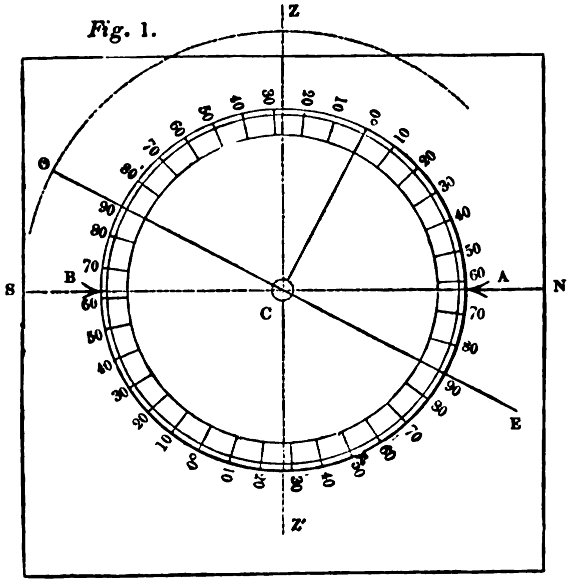
1 1 3 | 3 5 5

This method makes the circumference too great by about twenty-seven hundred-millionths of the diameter, and is therefore abundantly exact. But for common purposes, take the circumference at three times the diameter and one-seventh of the diameter, which does not err more than about one part out of a thousand of the diameter, and still in excess; that is, the circumference is a little less than twenty-two-sevenths of the diameter.

CIRCLE, ASTRONOMICAL. Though almost all the astronomical and geodesical instruments which are at present used in measuring angles, are composed of entire circles, the term *astronomical circle* is ordinarily confined to those instruments of which the sole or principal use is the measurement of angles of altitude or zenith distance. In the present article we shall adopt this limitation, and restrict ourselves still further to a description of the construction and use of those circles which are either fixed in the plane of the meridian, as the *mural* and *transit* circles, or which continue to have the plane of the principal circle vertical, though turning upon an axis, as the *altitude* and *azimuth* circle. For other instruments which might be included under the term circular, the reader must consult the articles Equatorial, Repeating Circle, and Theodolet.

This article will be more intelligible with some preliminary explanations.

Fig. 1.



Let a circular plate, divided into 360°, turn round a concentric axis C, fixed into the block S N, so that the line E O, moving with the circle, and in which direction the observer is supposed to look, can be placed in any direction up or down. A and B are two pointers attached to the block, and in a line passing through the centre. The block and circle are supposed to be upright, the axis C and the line A B horizontal. Also when the line of sight is vertical, or E O coincides with Z′Z, 0° of the divisions ought to be exactly under the pointer A. It is evident when the line of sight is moved through any angle into the direction E O, that C 0° must have moved through an equal angle, and that the ∠ Z C O = ∠ A C 0°, or the arc A 0°. Hence if an object is seen in the direction E O, its *zenith distance* Z C O will be the angle pointed out upon the divided circle by the pointer A. This angle is technically called the *reading* of A. The line E O represents the direction of plain sights, or the line of sight of a telescope, sometimes called the *line of collimation* (from *collimare*, said by Facciolati to be a mistake for *collineare*).

If when E O is vertical, A points a little above or below the 0°, or zero of the divisions, the difference from 0° is called the *error of collimation*, which may be corrected by shifting the position of A; but when the quantity and direction of the error are known, there is no need to make any alteration. For instance, let A point to 2° when the line of sight is vertical, then it is evident that when the line of sight is in the direction E O, the zenith distance will be equal to the arc from 2° to A, or 2° must be *subtracted* from the *reading* of A. If E O be directed anywhere between Z and N, then 2° must be *added* to the readings of A. In fact the pointer may be placed anywhere in the circumference of the circle, and the divisions may commence in any part of the circle without at all affecting the accuracy of the measurement of angles of zenith distance; but a very large error of collimation would be inconvenient in practice. The second pointer B, if exactly in a diameter with A, and the divisions perfect, would evidently give the same result as A. This also may have an error of collimation, which may be treated precisely as that of A; or rather, the error of collimation for the *mean* of two or more pointers is determined at once and by the same operation. Two readings have this advantage over one, that if some of the divisions should be erroneously placed, it is not likely that equal errors in the same direction should fall at the same time under both pointers; and in any other supposition, the mean of the two readings will be affected by a less error than one of them. Hence the advantage of multiplying the readings for lessening the errors of division; it is evident that what is improbable for two, will be all but impossible for six, which is the number used in the Greenwich circles. There is however another and more sensible advantage in two opposite readings above one. Conceive the whole circle to be moved towards Z, or Z′, or pushed sideways towards N, or S; still so long as E O continues to be parallel to itself, which it must be if it continues to be in the direction of a very distant object, the sum of the readings of A and B will remain the same; whatever one loses the other will gain. Hence it is not necessary that the axis should be truly circular, or that the centre of the axis should be exactly concentric with the centre of the divisions, which last requisite is not easily accomplished in the present construction of English dividing engines. In all circles which have readings diametrically opposite to each other, the observer ought to consider each *pair* as only *one* reading of a *diameter*, and not as two unconnected readings. There is another form in which a circular instrument for measuring altitudes may be constructed; the divided circle may be fixed to the block, and the line of sight, E O, turn upon the axis C. In this case the pointers must be connected with E O, and revolve on the same centre. All the previous remarks are equally applicable.

The operation of noting the angles, or of *reading off*, has been described in its rudest form, as it seems to have been practised by the Greeks. We must here explain somewhat more minutely the use of the micrometer microscope. (For other modes of subdivision, see Vernier.)

Fig. 2.

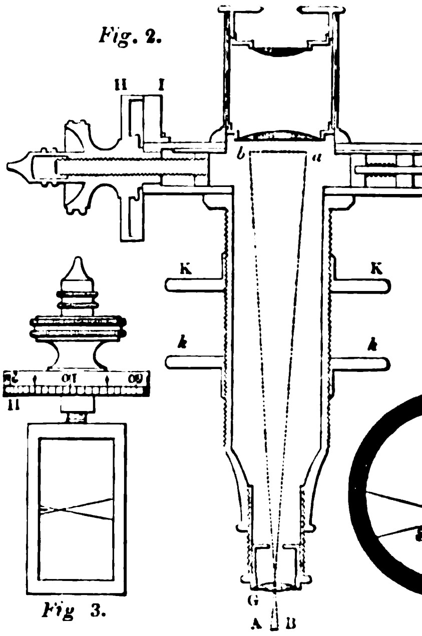


Fig 3.

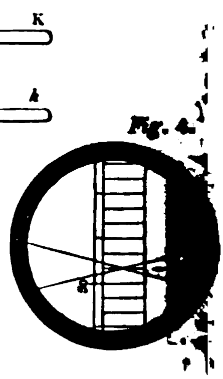

Fig. 4.

Fig. 2 is a *micrometer microscope*. A B is supposed to be the space between two divisions of the circle which is generally equal to 5′. The object glass G, which is sometimes, and with great benefit, made achromatic, forms at *ab* an inverted image of A B, as *ab*. Within the body of the microscope there is a slide, represented in Fig. 3. This slide is drawn forwards by a fine screw (generally of 100 threads to an inch), while it is held back by a spring to avoid *lost time*; it has two fine wires crossing at an acute angle as in the figure. The image *a b* should fall exactly on this cross, and the two lens eye-piece should be so placed as to give distinct vision of both. Also five revolutions of the screw should move the cross *exactly* from any division of the circle to the neighbouring one. The circular plate H is fixed by friction upon the head, and is divided into 60 parts, which correspond to seconds on the circle, and are read off by a pointer, I. The entire revolutions of the screw are counted by a sort of comb, or indented plate fixed near the wires, but not movable with them. There is a little projecting tongue of metal opposite the cross wires, which is seen between the teeth of the comb at each whole revolution of the screw. This microscope having its parts at the proper distance from each other, and being placed at the proper distance from the divided circle, must be supposed to be substituted for the pointer A, in Fig. 1 ; the tongue at 0 in the comb, and the zero of the divided head opposite to its index. If a division of the circle seems exactly to cut the cross at the angular points, the observer has only to note what division of the circle it is, and that is the reading, just as with the simple pointer. Generally however one division will appear above, and another below the cross. Since the divisions are seen inverted, the division apparently below the cross is the one really above, which, according to Fig. 1, and the position E O, is the division immediately less than the position of the microscope or pointer. Turn the screw round until the appearance is exactly the same as in Fig. 4, and suppose that the tongue has moved over two teeth, showing two revolutions of the screw, and the index is half way between 33 and 34 on the divided head, then 2′ and 33″·5 are to be added to the degrees and minutes of that division. Now that division is 50° 5′, therefore the true reading is 50° 7′ 33″·5. What has been said as to error of collimation holds good with a microscope as with a pointer. When the line of sight E O falls between Z and N, then the next least division will be really below, but apparently above the cross, and the measurement should be made to it. The screw in this case must be turned the other way, and instead of the divisions of the head shown by the index, their difference from 60 must be taken for the seconds. A little caution and experience will guard the observer against mistake. The length of the microscope can be altered by screwing the tube in which G is fixed, and the microscope can be shifted in its support to and from the circle by the nuts K K, *k k*. It is evident that by these two movements the size of the image can be altered as well as its situation with respect to the cross wires. (See the figure of the altitude and azimuth circle for the mode of mounting the micrometer.) The apparatus of the micrometer microscope, shown at Fig. 3, is frequently attached to the eye-end of a telescope, and is placed in the focus of the object glass. The wires are then placed across the slide and at right angles to it, so as to be parallel with other wires of the telescope. If these points are clearly understood, the reader will find no difficulty in understanding the rest of this article. [See MICROMETER.]

The earliest application of a circle to astronomical purposes is described by Ptolemy (*Almag.* i. 10), who calls it from its use, a solsticial circle. This consists of a smaller circle turning freely within, and in the same plane with a larger and fixed divided vertical circle. Two small projecting prisms are placed in a diameter of the inner circle for a line of sight, and pointers are also fixed on the inner circle which move on the face of the outer circle. The instrument thus formed is to be carefully adjusted by a plumb line and meridian line in the plane of the meridian. In observing the sun, the inner movable circle was turned round until the shadow of the upper prism exactly covered the lower prism, when the pointers marked the corresponding division upon the outer fixed circle. The inner circle seems to have been employed as the most accurate mode of giving a rotatory motion to the *line of collimation*, concentric with the divided circle. If a bar, carrying the line of sight and the pointers, be supposed to revolve on an axis, it is the second case of Fig. 1. The language of Ptolemy does not inform us who was the inventor of this instrument, or even that it was ever made or used. Delambre conjectures with some probability, that it is due to Eratosthenes, though he inclines to think that the celebrated measure of the obliquity of the ecliptic by that astronomer, viz., that the distance between the tropics is equal to $\frac{11}{83}$ of the circumference, was deduced from observations with the gnomon. However that may be, it is certain that the *solsticial circle* was the best-contrived instrument of which we find any account until the time of Roëmer; and it bears, as will be seen, a very close analogy to the modern mural circle of Troughton.

Except the complicated astrolabe of Hipparchus, which consisted of five concentric circles, so contrived as to have one circle in the plane of the ecliptic, and another at right angles to it, we do not find the entire circle employed in large instruments before the time of Tycho Brahé, and then only for an equatorial. The supposed authority and example of Ptolemy, who proposed a quadrant, and the desire of increasing the sensibility of instruments, by enlarging the scale of the divisions, blinded astronomers to the more solid advantages of the entire circle.

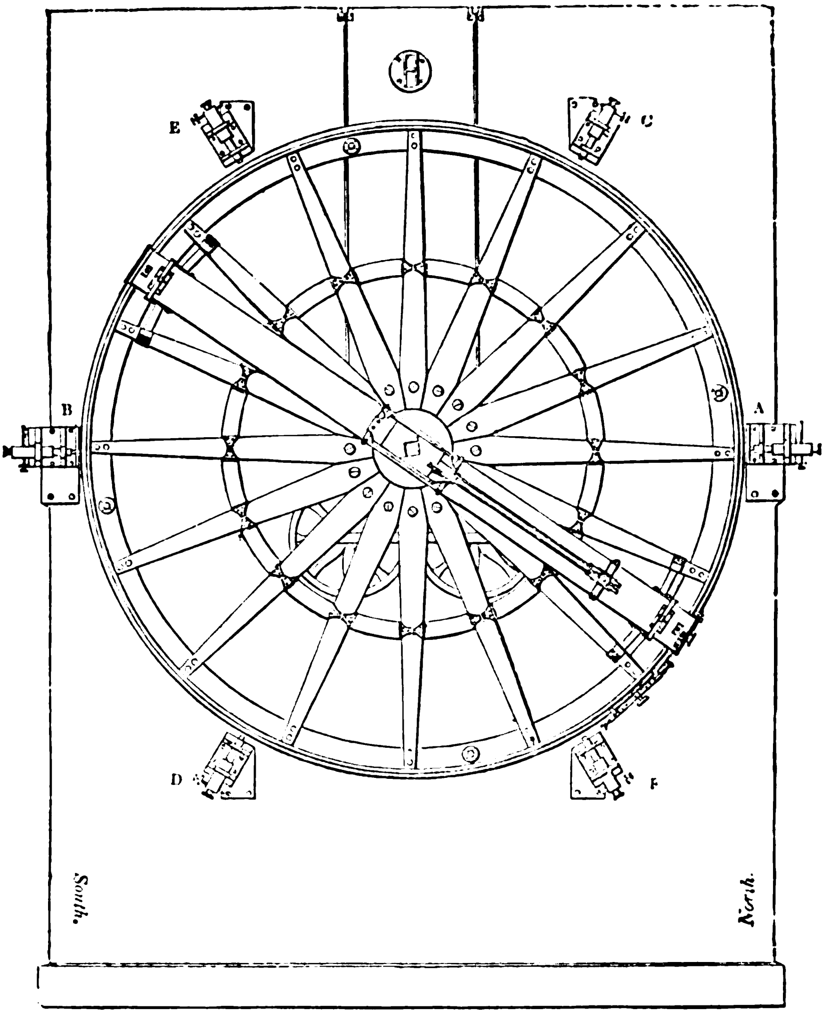
In 1704 Roëmer erected his *Rota meridiana*, or *transit circle*, in his private observatory 1^{m} due west of the astronomical tower of Copenhagen. He had invented the simple transit and the altitude and azimuth circle about fourteen years earlier, and in this new instrument he very happily combined the qualities of a transit telescope with those of a meridian altitude circle. In a letter to Leibnitz, 15th December, 1700, he had already said, 'that the quadrant and sextant ought no longer to be used, and that he would rely more on an entire circle of four feet than on a quadrant of a ten-feet circle.' (*Miscell. Berolin. continuat.* ii. p. 276.) A description and figure of the Rota meridiana are to be found in the *Basis Astronomiæ*, p. 143, Tab. viii., of his pupil Horrebow, *Hafniæ*, 1735, with a specimen of three days' observations. The altitude and azimuth circle is described in p. 43, and figured in Tab. ii. of the same work.

The *Rota meridiana* of Roëmer was a divided circle set upon a hollow double cone, at right angles to the axis of the cones, and concentric with them, the circle being near one end of the axis. The divisions were read by two microscope verniers, fixed in a diameter of the circle on one of the supports of the axis. For general purposes, this is perhaps as well a designed instrument as has ever been constructed, yet it was not imitated till about three or four years ago, when a similar construction was recommended by Mr. Pond, and adopted for the observatory at Paramatta. A second on a much larger scale is just finished for the observatory at Oxford; both these are by Mr. T. Jones. Notwithstanding the advice and practice of Roëmer, it does not appear that the entire circle was used for astronomical purposes until Mayer proposed his *repeating reflecting circle*. His description was published in 1770 (*Tabulæ Solares*, p. 21, plate ii.), but the repeating reflecting circle did not come into use until modified and perfected by Borda about 1787.

In 1784 the Danish astronomer Bugge published his *Observationes Astronomicæ, Hauniæ*, in which he gives a figure and description of a vertical circle of four feet diameter revolving in azimuth, p. liii., Tab. viii. and ix.; it seems a smaller one had been used in the survey of Denmark as early as 1762.

Ramsden undertook an altitude and azimuth circle for the observatory of Palermo in 1788, and completed it 1789. This is described by Piazzi (*Della Specola Astronomica di Palermo*, 1792), with four plates of the instrument and its details. (See too *Pearson's Astronomy*, vol. ii., p. 413, plate xxiii.) It is with this circle that the declinations of Piazzi's celebrated catalogue were determined. In 1792 Troughton perfected his altitude and azimuth circle; and in 1793 Mr. Francis Wollaston published in the *Philosophical Transactions* a description, with a plate, of his transit circle: Borda's repeating circle seems to have been first used about 1787, in connecting the meridians of Paris and Greenwich. The advantages of the circular form were now appreciated; its superior strength and symmetry, the elimination of any error of excentricity by opposite readings, and the diminution of errors of division by increasing the number of readings, or by reversing the instrument, were placed beyond dispute. Various alterations were made in parts of these instruments, and new contrivances and conveniences applied, but nothing very novel in principle was struck out till Troughton erected a six-feet mural circle at Greenwich in 1812. After some controversy this form has been generally adopted in those British observatories which can afford a second observer for the transit.

The limits of the present work will not allow a detailed account of any one instrument, and still less a description of the numerous variations which have been introduced according to the views of astronomers and artists. We shall give a general view of the two most essential forms, the mural meridian circle and the altitude and azimuth circle, as constructed by Troughton and his school.



[Greenwich Mural Circle, by Troughton; diameter six feet.]

The accompanying figure of the mural circle of Troughton is copied from that prefixed to the Greenwich Observations for 1812, with the subsequent alterations. The circle is framed as strongly as possible (it might, perhaps in some cases, be advantageously cast in one piece), and is fixed at right angles to and concentric with a long, hollow conical axis. This axis rests and turns in two collars, one towards each end of the cone, fixed at the front and back of a stone pier, three or four feet in depth, and there are four screws at the back for adjusting the horizontal axis in inclination or azimuth. The circle is divided on its edge to 5′, upon a narrow ring of gold or other metal let into the rim; the divisions are read by the six micrometer-microscopes at A, B; C, D; E, F. The telescope is fixed at right angles upon an axis which works within the hollow conical axis of the circle, and can be moved upon the circle into any position; it is held fast by clamps towards the object and eye-end. At the eye-end there are three or more vertical, and one horizontal wire, and a micrometer, which carries a second horizontal wire parallel to the fixed wire. To prevent wear, and to give ease and smoothness to the motion of the circle, two large friction wheels are suspended in front of the pier from the arms of two levers, which by counterpoises may be made to support the whole or part of the weight of the instrument. They press upwards upon a ring on the axis, between the circle itself and the pier. There are several small contrivances which need not here be mentioned, as our design is only to give an idea of the nature of the instrument. For a more minute description the reader must consult *Pearson's Astronomy*, vol. ii., pp. 472, 488, plate xx. The above description belongs to the mural circle as constructed by Troughton. In one or two later instances the collars have been exchanged for Y's, that is, angular notches in pieces of metal, in the hope of making the instrument serve for a transit; but this has not, we believe, yet been performed satisfactorily. Dr. Robinson, in the circle made for the observatory at Armagh, preferred having the divisions cut on the back of the instrument, and the microscopes fixed on the edge of a circular pier, with several other alterations (for which see *Mem. Ast. Soc.*, vol. ix.) The divisions of the circle are cut by Troughton's method. [See GRADUATION.]

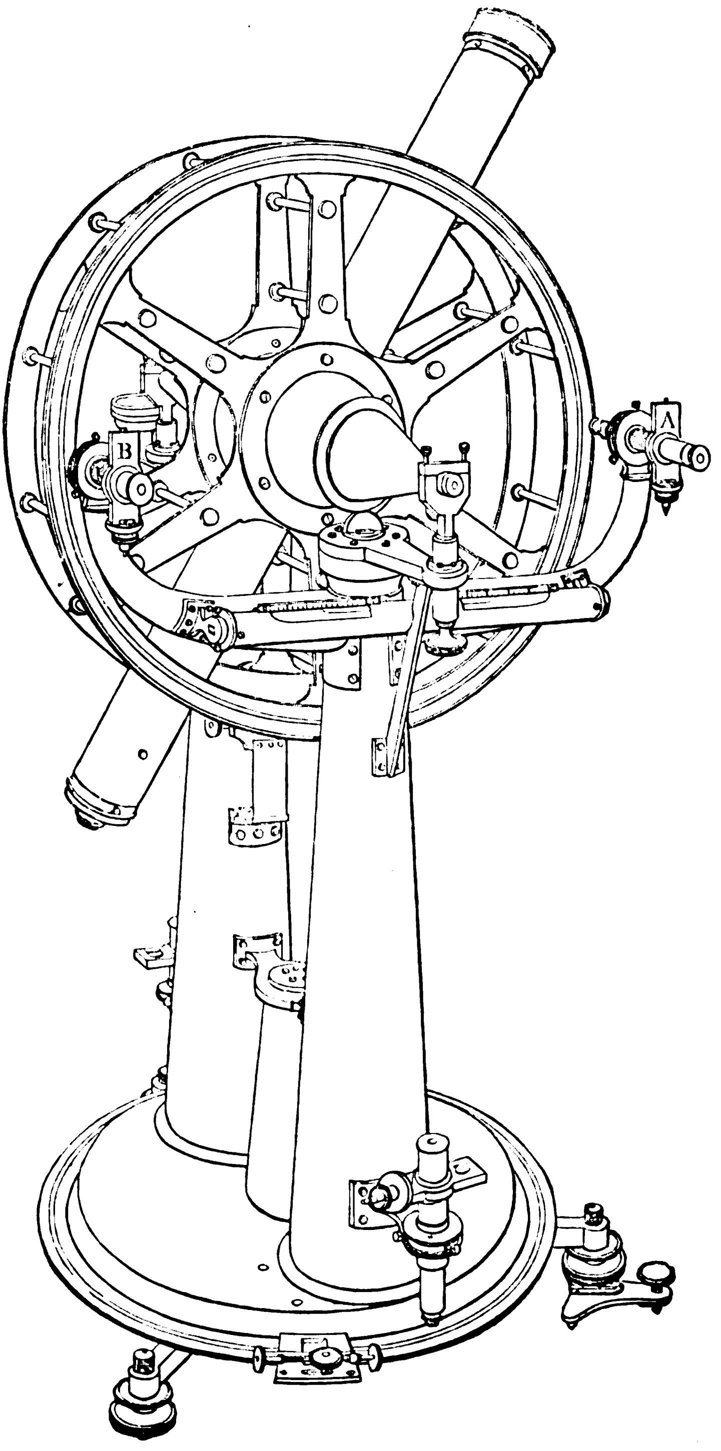
After the instrument is erected on its pier, the axis must be placed horizontally, or the plane of the circle vertical. This may be done by a plumb-line apparatus, which generally accompanies the instrument; or more accurately by making a star pass the meridian wire at the same time when seen directly, and also when seen reflected in a trough filled with mercury or water, &c. The four screws at the back of the pier supply the means of effecting this. The second adjustment, or placing the line of sight at right angles to the axis, may be performed by two distant marks to the north or south of the circle, which have been previously correctly placed by means of a transit; or by a collimating transit [COLLIMATOR]; and finally, the instrument may be placed in the meridian, either by a mark, or by observations of circumpolar stars above and below pole, or by observations of high and low stars, just as a transit. [TRANSIT.] Or the position of the plane described by the line of sight with respect to the meridian, may be determined by comparing the passages of stars over the meridian, as observed with the circle and with the transit at the same time: when the law of the errors being known, and also the amount of their sum, their respective values are easily ascertained and corrected. It may, however, be remarked, that small errors in any or all these adjustments will not vitiate the results and that the moon is the only celestial body sensibly affected by ordinary variations from the true meridian.

The mural circle is used in measuring angular distances on the meridian, and the observation is performed thus:—The telescope is pointed nearly in the direction of the object, and the circle fixed by the clamp in that position: then the instrument is moved by the slow motion-screw of the clamp, until the horizontal wire exactly cuts the star in two, or *bisects* it, at or near the meridian wire. If the object be the sun or moon, or a planet having a considerable disc, the wire is made a tangent to its illuminated edge. With the sun, a dark glass is put on the eye-end to protect the sight, and at night a lamp placed opposite the centre of the telescope throws light through a glazed aperture, which is again reflected by a polished metal ring placed at an angle of 45° with the axis of the telescope, so as to illuminate the field of view and show the wire distinctly. This light can be modified at the pleasure of the observer, and the apparatus for this purpose is shown on the telescope. The mural circle has been used somewhat differently by different observers. When Troughton proposed a mural circle for Greenwich, he said that all observations should be considered as distances from the pole; and that the place of the pole on the instrument (*i. e.* the reading of the circle when the telescope points to the pole) should be determined from the successive upper and lower culminations of Polaris, and other close circumpolar stars. The north polar distances of stars might thus be measured and registered with the help of a correct table of refraction, without an accurate knowledge of the latitude of the place, which is only wanted for converting polar distances into altitudes or zenith distances, for computing refraction and parallax. The latitude of the observatory might be subsequently deduced by comparing the polar distances of stars near the zenith, for instance, of γ Draconis at Greenwich, with the zenith distance of the same star observed by the zenith sector or the zenith tube. [ZENITH SECTOR.] The observations could be checked by combining them with observations by reflection, when the star is seen reflected from the surface of a trough of quicksilver. In a climate so variable as that of England, Mr. Pond, then astronomer royal, found it advisable to modify the plan thus suggested. He first formed an approximate catalogue of the north polar distances of several stars by these or other means, which he perfected as follows:—Assuming the approximate catalogue to be correct, every future observed place, compared with the place computed from the catalogue, presented a difference, which he called the *index error* of the instrument, and from the observations of several stars he obtained a *mean* index error. This mean index error was then applied to each of the observations, and a corrected catalogue thus produced, which by repeating the process leaves no constant error except such as may be common to all the stars employed; such, for instance, as an original error in assuming all the polar distances too large or too small. Now an error of this nature affects all stars at their superior passage alike, and makes them all equally appear too near to or too far from the pole; but it affects the superior and inferior passages of the circumpolar stars by equal and contrary quantities. Hence the difference between the mean of two sets of observations of Polaris and other circumpolar stars, one set being deduced solely from upper, and the other solely from lower culminations, is clearly equal to twice the mean error in the assumed place of the pole with respect to the stars; and this correction being applied to all the stars, a new and more correct standard catalogue was formed, to be again corrected and improved by future observations. It is evident that the errors of the originally assumed catalogue are now wholly eliminated. By shifting the place of the telescope on the instrument, fresh divisions were brought into use for each star. The accuracy of the tables of refraction employed might have been tested by the agreement of near and distant circumpolar stars, in assigning the same value for this correction to the polar point. The only defect in this method seems to be, that it assumes the accuracy of the instrument or the accuracy of the tables of refraction; and that if either or both be imperfect, the final results are not in a form suited to investigation.

Another mode was adopted by Mr. Pond after 1824, when a second mural circle, made by Mr. T. Jones, of Charing Cross, was erected at Greenwich. Suppose several stars to be observed the same evening in two groups, which call A and B. All the stars in group A are observed by both circles by direct vision; the stars of group B are observed directly by one circle, suppose Jones, and by reflection, by Troughton. Let the mean of the readings of group A, by Jones, exceed the mean of the readings of the same group by Troughton, by m''; then it is clear, the instruments continuing in the same state, that if from the observation of any other star, by Jones, you *subtract* m'', you will have the reading which Troughton would have shown, barring accidental errors, and *vice versâ*, that on *adding* m'' to any observation by Troughton, you will get the corresponding observation, with the same exceptions, which would have been made by Jones. Again, let a star in group B be taken, and let D be the angle read off by Jones, the star being then seen directly, and R the angle by Troughton, the star being seen by reflection. Then according to what has been said above, $D - m''$ is the angle which Troughton would have given by direct vision, and consequently the angle between the star seen directly and by reflection, which is twice the altitude of the star, $= R - D + m''$, or the altitude $= \frac{R - D}{2} + \frac{m''}{2}$. Again, as the reading which corresponds to the horizontal position of the telescope is evidently D + altitude of the star by Jones, and R — altitude or depression of the star by Troughton, we shall find for that reading, or the *horizontal point*, as it is called, in Jones, $\frac{R + D}{2} + \frac{m''}{2}$, and in Troughton, $\frac{R + D}{2} - \frac{m''}{2}$. In this way each of the stars in group B gives a fresh value for the horizontal point in each instrument, and the *mean* of the determinations for each circle is taken as the basis for reducing every observation by that circle. Thus the reading of each direct observation of the stars in group A with Troughton, being *subtracted* from the mean value of its horizontal point, will give the true altitude of the stars in group A, and the same value of the horizontal point being *subtracted* from every reflected observation of group B, by this circle, leaves in like manner the true altitude, which is all the astronomer demands from the circle. This method requires the groups A and B to be sufficiently numerous for eliminating the chance errors of mere observation, and to be distributed over various parts of the circle to destroy faults of form or of division. It is also supposed that the circles are instruments of nearly equal goodness, and that each is as perfect as art can make it. If they should be defective, the discrepancies in the partial determinations of the horizontal point will show it, and the astronomer must then attempt to discover the law and the cause of the defect. The combination of two circles to form, as it were, one instrument, has only been tried at Greenwich, but there it has proved eminently successful; Mr. Pond's opinion, after long experience, being, that *the pair were more than twice as powerful as a single one.* The same astronomer suggested an analogous method for one circle. Observe the groups A and B all *directly* one night, and on a following night observe A *directly*, and B by reflection. A comparison between the groups A on different nights (the change of place in the stars and in the refraction being allowed for) will give you the variation or change of place of the instrument and microscopes; and by applying this to the stars B, observed on either of the nights, you will have observations of the same stars on different nights, by direct and reflected vision, but with an *unchanged* instrument. Hence the double altitudes of B are found, and also the horizontal point for one of the nights which when increased or diminished by the variation above found, is the horizontal point for the other. This method, or one similar to it, is, we believe, followed at Edinburgh and the Cape of Good Hope; and it is found that these instruments are so steady and unfluctuating, that the same value of the horizontal point results from the observations of several days. In this system the observations of one day are made dependent on those of another, when the atmospheric circumstances may be widely different. It has, however, one advantage over the previous method with two circles, that it places more directly in evidence the individual errors of the instrument. The differences which may be found between the partial determinations of the horizontal point on the same night, and on different sides of the zenith, will show what reliance is to be placed on it and on the observer.

When the mural circle was erected at Cambridge, Professor Airy selected the following plan of determining the horizontal or zenith point. The micrometer attached

to the eye-end of the telescope has already been mentioned. The value of a revolution of this micrometer having been very exactly measured, and the parallelism of its movable wire with the horizontal wire carefully ascertained, and also the reading of the divided head when the two wires coincide, the telescope is set pretty nearly in the position at which a star by *reflection* would be on the horizontal wire, the circle is then firmly clamped, and the microscopes are read off. When the star is at a convenient distance from the meridian wire, it is bisected by the micrometer wire without stirring the circle. When this is done, and the time noted, the circle is unclamped, and the star bisected by *direct vision* on the fixed horizontal wire, by turning the whole circle round, and the time is again noted. If the star had been observed in both instances upon the meridian and upon the fixed wire, it is clear that the reading corresponding to the horizontal position of the telescope would be half way between the readings of elevation and depression, or = $\frac{R + D}{2}$. The correction to the meridian is easily found and applied, the times being known. Again, if the distance between the fixed and micrometer wire be equal to n'', it is clear that the reading of R is greater or less by n'' than it would have been if the observation had been made with the fixed wire, and that the further correction for the micrometer is made simply by the addition or subtraction of $\frac{n'}{2}$ to the value already found of the horizontal point. In the Cambridge Observations, Professor Airy tabulated the reading corresponding to the zenith position of the telescope. From a mean



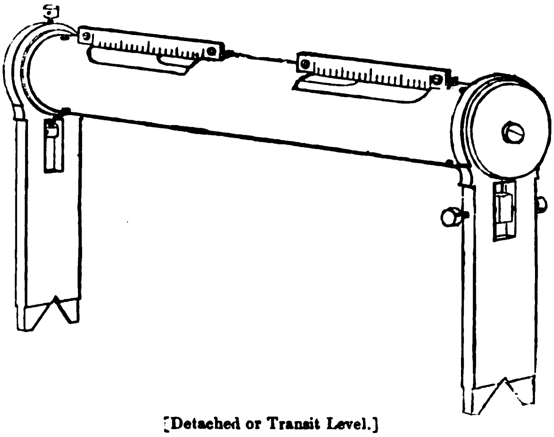
Eighteen-inch Altitude and Azimuth Circle, by Troughton and Simms. 1836.

of such determinations the reading of the zenith point is settled, and all observations made in the ordinary way, reduced to altitudes or zenith distances. For this mode of observing, the micrometer should be exquisitely perfect, and carefully watched. On comparing the zenith points deduced from low and high stars, to the north and south of the zenith, Professor Airy discovered some anomalies, the causes of which have not yet been fully ascertained. (*Cambridge Observations*, 1833, p. 27.) They seem, however, to exist in other mural circles, and possibly in circles of a different construction.

The micrometer microscopes, in what has been said, are supposed to be exactly adjusted, so that five revolutions of the screw carry the cross of the wires precisely over a space of 5′ on the circle. It is not possible to make this adjustment with perfect accuracy, nor would it be permanent; but it is not necessary. By examining the value of the *runs*, as they are called, *i. e.*, the measures in revolutions and parts of the screw of the 5′ spaces in the circle, a mean value of the measure of 5′ by the six microscopes is obtained, from time to time, which may be a little greater or less than five revolutions. In this case, the mean of the micrometer readings, *i. e.*, of the single minutes and parts, must in each observation be altered in the proportion of the value thus ascertained to 5′. If, for instance, the mean value of the 5′ spaces on the circle were apparently 5′ 5″.1 by the microscopes, $\frac{1}{60}$ must be subtracted from the minutes and seconds indicated by the mean of the microscopes. For actual adjustment, the following directions may be useful. A micrometer microscope is adjusted when the image of the divisions of the circle is formed upon the cross wires of the microscopes, and its size is exactly equal to five revolutions of the screw. Suppose the vision of the wires and of the divisions to be perfect, but that the space of 5′ is passed over by four revolutions and fifty parts of the screw. It is evident that the image is too small, and it must be made larger by drawing out by the screw the object glass G, and bringing it nearer the limb. In this case however the image is formed between the wires and the eye-piece, and therefore the whole body of the microscope must be drawn from the circle until the image falls on the cross wires. It will now be found that the image of 5′ is larger than before, and it must be again measured by the screw. In this way by gradual attempts the microscope may be perfectly adjusted, but the operation, if complete accuracy be aimed at, is very fatiguing and troublesome.

The general form of the altitude and azimuth circle will be seen from the woodcut. The lower, horizontal, or azimuth circle, is fixed on three strong radii which have foot screws at their extremities, and a strong vertical steel axis rising from their intersection. On this axis the whole of the upper works move freely and smoothly on a conical cap accurately fitted and ground to the top and bottom of the axis. On the lower part of the cap is fixed a broad circular plate on which the two pillars rest which support the circle and telescope. The microscopes for reading the azimuth circle are fixed on the pillars. Outriggers stand on the top of pillars, each of which carries a notch or Y, which can be raised or depressed by a screw. The vertical, altitude or declination circle is framed with a view to strength and lightness, and its divided face is read by two microscopes placed on the end of the curved tube, which is formed something like a pair of horns, and fixed across the top of one of the pillars. The circles are usually divided to 5′, and subdivided by the micrometer microscopes to seconds. The graduation of the horizontal circle generally runs from 0° to 360°, the vertical circle is differently divided according to the pleasure of the artist or observer. A little consideration will enable any one to apply the rules given for reading microscopes to each particular case. We shall speak indifferently of altitudes and zenith distances, since they are immediately derivable one from the other. The wires of the telescope are illuminated by a lamp which shines in at one end of the cross or transit axis of the vertical circle, and is reflected on the wires by a pierced polished ring set diagonally. There are two sensible ground levels, one of which is attached to the horns supporting the upper microscopes; another, which is free, can be applied through the openings of the circle to the pivots of the cross axis. This cross level and its adjusting screws will be understood by the accompanying figure.

There are clamps and slow moving screws to each circle to fix them, and to give the power of bisecting any object with the telescope.



[Detached or Transit Level.]

The first adjustment is that of setting the vertical axis perpendicular to the horizon. Turn the instrument until the fixed level is nearly parallel to two of the foot-screws, and place the bubble in the middle by the foot-screws. Then moving the instrument half round in azimuth, bring the bubble again to the middle; half by the foot-screws, and the other half by the screws which raise or depress one end of the level. If this is carefully done, and the circle restored to its original position, the bubble will be still in the middle, but if not, it must be brought there, half by the foot-screws, and the rest by the level-screw. Now, turning the instrument a quarter round, through 90°, bring the bubble into the middle of the scale by touching the third foot-screw. This is generally placed in front and towards the observer, and rests on a small lever apparatus, represented in the figure, which supplies a very delicate slow motion, contrived, we believe, by Borda. When the operation is successfully performed, the bubble will remain in the centre, whatever azimuth the instrument is directed to. It is not necessary in practice to touch the screw which adjusts the level if the error be very small. The divisions of the level scale corresponding to both ends of the bubble should be noted before and after reversion, and the mean taken. Let the foot-screws be called E and W, and the ends of the level towards them be distinguished by the same letters, and the scale of the level be numbered from the centre to each end, and suppose the readings be

	E	W	
In the first position .	67″.4	48″.2	
In the reversed position	59″.6	56″.0	
Mean. .	63 . 5	52 .1	difference = 11″.4.

The mean readings would have been the readings of the level, if the level itself had been in adjustment. It is evident that E is too high, or W too low, by half the difference, or by 5″.7, and one of the foot-screws must be turned enough to shift the bubble 5″.7 in the right direction. Troughton always moved both E and W an equal quantity in contrary directions for this adjustment, which in many cases is very much better. If that is carefully done, the E readings will be diminished, and the W readings increased by 5″.7, and they will stand thus:—

	E	W
In the first position . .	61.7	53.9
In the reversed position	53.9	61.7

or the bubble keeps the same position *in its scale* before and after reversing, and the axis is vertical to the line joining the two foot-screws. The bubble must be placed at the same divisions when over the third foot-screw, and the axis is truly vertical. The difference between the last-mentioned readings is 7″.8, and the half of this, or 3″.9, is the quantity through which the bubble should be moved by the level screw to complete its adjustment, if that be desired; but if the true value of the divisions of the scale be known, and it is also known that this does not sensibly vary with the temperature or from other causes, it is useless to adjust very scrupulously, since the ends of the level must always be read and noted, and the difference allowed for by a careful observer. In some larger instruments of this construction, the vertical axis is adjusted by a plumb line, which

Ramsden and Troughton applied in different ways. One of these applications will be described under ZENITH SECTOR; but we are inclined to think that the ground level is more accurate, while it is incomparably more convenient than the plumb line, for small circles, which move freely in azimuth, and are used agreeably to their construction. The vertical axis being properly placed, the cross axis of the upper circle is next to be set horizontal. Pass the detached level carefully through the openings in the circle, place its notches on the pivots of the axis, note the ends of the bubble, exactly as before, reverse the level and note the ends again. Suppose the results to be,

	East End.	West End.
First position . .	6.24	8.43
Reversed position .	7.96	6.71
Mean . .	7.10	7.57

hence the difference between the mean readings is 0.47, or the west end is higher than the east by 0.235. The bubble must be moved this quantity towards the east by raising the east, or depressing the west pivot. There is a screw under each pivot for that purpose. It is convenient to have the scale divided into parts, of which the units are 15″ of a degree.

The microscopes should be adjusted, if that be required, in the manner already described, but we recommend amateur observers, at least, to have the body of the microscopes made unalterable, after the maker has settled both the adjustments, by pinning together the body and tube which carries the object-glass. Both adjustments will then be performed by making the 5′ spaces equal to five revolutions of the micrometer screw, simply by shifting the body of the microscope a little nearer to or farther from the instrument. This should be done pretty carefully, but any remaining error may be corrected as in the mural circle. The microscopes (there are generally a pair to each circle) are finally to be placed in a diameter of their respective circles, and nearly in the middle of the concentric lines, which contain the divisions. There are screws in the tubes by which the microscopes are mounted, which allow them a little motion in any direction, and the cross wires are thus brought to bisect divisions 180° apart. This requires no particular exactness, and may be done at once for the azimuth circle. The upper microscopes may be adjusted approximately. The optical part of the instrument must now be put into order. At the eye-end of the telescope there are generally five or seven vertical and three or five horizontal wires, *i.e.* fine lines of cobweb, raw silk, or any very delicate and uniform fibre. To place these in the focus of the object-glass, apply the highest magnifying power you have got, bring the wires to distinct vision, and look at a bright star. The wires and eye-piece are fixed on a piece of tube which moves stiffly within the tube of the telescope, and this must be pushed in or drawn out till the star is seen perfectly round and surrounded with rings, the wires being at the same time sharply defined. This adjustment may be completed or verified thus:—The pole star, or any circumpolar star, may be bisected by the vertical wire when near its greatest elongation, or by the horizontal wire when near the meridian. In the former case the eye is to be moved on each side, in the latter up and down; and if the star continues bisected, and there is no dancing of the star on one side or other of the wire, the position is correct. When the star moves contrariwise to the eye of the observer, the tube must be pulled out, as the image of the star is then formed between the wires and the eye, and the wires must be brought to the same place. When they move the same way, the tube is to be pushed in, until the image is formed exactly upon the wire. Any error must be corrected by gradually pushing the tube in or out. When this has been once successfully done, a notch for verification should be made to save all future trouble. The vertical wires are now to be set at right angles to the axis. Take any well-defined object, either a sharp distant terrestrial mark, or the wires of a subsidiary telescope [COLLIMATOR], or a circumpolar star at its greatest elongation. Bisect this at the centre of the middle wire, and move the telescope up and down until you see the object at the top and bottom of the field. If it is not bisected there, twist the movable tube round, and so bisect it, and repeat the operation until you are satisfied. The middle horizontal wire, if a correct position of that is preferred, must be adjusted, by twisting the tube until a star on the meridian runs along the horizontal wire by its own motion, the azimuth circle being fixed; or by moving the instrument in azimuth after having bisected Polaris or a circumpolar star near the meridian, on that wire. There are screws above and below the tube at the eye end, which should now be tightened. To make the central and vertical wire describe a great circle, bisect a well-defined object, as near the horizon as may be, read the horizontal microscopes, turn the instrument 180° in azimuth, and observe again, reading the same microscopes. If the means of each pair of readings, before and after reversion, differ *exactly* 180°, the wire describes a great circle; if not, move the instrument half way to 180° by the clamp screw, and bisect the object by turning two antagonist and pulling-screws near the eye-piece, which draw the wire plate to either side; repeat the operation until you are satisfied. If the horizontal clamp is strong enough, the circle may be taken out of its axis and reversed as an ordinary transit [TRANSIT]. The upper microscopes may now be correctly adjusted. Observe any object which does not alter its altitude on the middle horizontal wire, and read the upper microscopes; turn the instrument through 180° of azimuth, and observe the object again. Move the circle to exactly the middle of these two readings (which will be near either 0° or 90°), when the telescope is in the zenith, and then by the adjusting screws set the crosses of each of the microscopes exactly on 0° or 90°, as the case may be; the microscopes are then in a diameter, and the error of collimation in altitude is also destroyed. As this correction is altered by any alteration of the apparatus for levelling the horizontal axis, and as few observers like to meddle with the adjustments of their microscopes, the microscopes can be brought into a diameter after the axis is made horizontal by raising or lowering each of the levelling screws a small equal quantity; but though it is convenient that the microscopes should read nearly the same angle, it is not at all essential to accuracy, and the error of collimation must always be ascertained or eliminated by the mode of observation.

We shall always suppose every observation to be a *mean* of two, one made face east and the other face west, unless the contrary be said or implied. In this case there is no error of collimation.

The altitude and azimuth circle was, as has been stated, invented by Roëmer, though a quadrant moving freely in azimuth, and with a graduated horizontal circle, was used by Hevelius. It is the most universally useful of all astronomical instruments, and is both portable and accurate. In delicate hands, and with some power of calculation, it is capable of performing a great deal of good work. Besides being an excellent geodesical instrument [THEODOLET], it is, when placed in the meridian, an accurate, though not very convenient transit. It may be used in this position as a meridian or transit circle, for determining at once the right ascension and zenith distance of any unknown stars. In this case the horizontal point must be got by combining observations taken directly with others by reflection, in the manner already described in the mural circle; or else several standard stars may be observed, and their instrumental places compared with their computed places; the mean of these differences is to be applied as an index error to correct the observations of unknown stars exactly as in Mr. Pond's first method with the mural circle. In this mode of observing there is no reversion.

The principal merit in the altitude and azimuth circle is, that it can be moved in azimuth without injuring its accuracy as a measurer of zenith distance. Let us suppose a navigator in a strange place with such an instrument and a time-keeper, of which the error is unknown. This should mark sidereal time. The instrument must first be nearly adjusted, and the approximate meridian selected. This will be known near enough by shifting the instrument in azimuth till it is found that a star, which is bisected by the horizontal wire, continues to be bisected for a short time. Observe the zenith distance of some known star in this direction, and this will give an approximate latitude. The time and the azimuth of the star should also be noted. Now observe the zenith distance of another known star near the prime vertical, the time deduced from this and the approximate latitude will be a very close approach to the true sidereal time at the place. The original latitude from the first observation may now be corrected by a more accurate knowledge of the time, and the azimuth of the star at the time of observation be deduced, whence the reading corresponding to the meridian position of the instrument is also known. If these observations have been managed with any skill or discretion, the latitude and time are now found near enough for future calculations[*].

To ascertain the latitude with the utmost precision, several standard stars are to be observed near the meridian, and, if it may be, at pretty nearly equal distances from the zenith, north and south, to 70° or 80° zenith distance. A few minutes before the star comes to the meridian, bisect it near the centre of the middle horizontal wire, noting the time of bisection. It is perhaps more exact to place the wire close to the star, and then, leaving the vertical circle untouched, to move the whole instrument by the horizontal clamp along with the star until it is bisected upon the wire by its own motion. The ends of the level and the upper microscopes are then read, the instrument is turned gently round 180° in azimuth, and the observation is repeated. The sum of the two angles (when each pair of readings is connected into one zenith distance) is twice the apparent meridian zenith distance of the star, affected by the want of verticality in the axis, which is known from the level, and by a small correction depending on the time of observation. It is clear that if the end of the level towards the eye end of the telescope is too high, that the foot-screw towards the observer should be lowered, in which case the telescope would point above the star, that is, show a less zenith distance than the true zenith distance. Hence the rule is, take the reading of the end of the level towards the object end of the telescope from the reading towards the eye end, halve the difference, and add this, when converted into arc, to the instrumental zenith distance. This may be done in each case, or the mean of the whole applied to the mean of the instrumental zenith distances. For the *correction to the meridian* the formula is,

$$\text{Corr.} = \frac{\text{cos. dec.} * \times \text{cos. lat.}}{\text{sin. zen. dist.} *} \times \frac{2 \text{ sin.}^2 \tfrac{1}{2} \text{ angle at the Pole}}{\text{sin. } 1''}$$

The first factor must be computed for each star, the latter is taken from a table which may be found in *Schumacher's Hülfstafeln*, or *Baily's Tables*, and in many collections of astronomical tables. The argument is the angle at the pole, that is, the difference between the moment of observation and the transit of the star. This correction is to be *subtracted* from the zenith distance of stars observed *above* the pole, and *added* to those observed *below* the pole. The mode of observing is generally known by the name of *circum-meridian*. We have here detailed the process as it refers to a single pair of observations, but several pairs may be taken, as many as can without hurry be got in a quarter of an hour on each side the meridian. With a good instrument and a careful observer, the latitude thus deduced from several stars will be very near the truth, if the observer employs a correct catalogue, such, for instance, as that of 1112 northern stars, published by Mr. Pond in 1833, or the catalogue of southern stars, by Lieut. Johnson, 1835: if he can observe the same circumpolar stars at their upper and lower culminations, he may obtain a latitude independently of any catalogue. If stars near the pole be observed, it is not necessary that they should be near the time of passing the meridian, but the reduction to the meridian zenith distance must be computed by an exact formula. There are special tables of Polaris for this purpose in the *Nautical Almanac*.

The time may be found by two or three methods. The zenith distances of known stars near the prime vertical, both to the east and west, may be observed, and the horary angle computed from the observed zenith distance and the known colatitude already found. In this case the altitude circle should be kept clamped, while the times of the passage of the star over each of the horizontal wires are noted, the mean is to be taken, and the instrumental zenith distance is to be corrected for the indication of the fixed level. Repeat the operation after reversing the instrument, and take the mean of the zenith distances, which will correspond very nearly with the middle time between the observations. From this zenith distance the error of the time-keeper is found. The mean of the errors deduced from an equal number of stars on the east and on the west prime vertical will be very nearly correct, and depend upon the divisions of the circle and the catalogue employed. Also the altitude circle being clamped, a star may be observed rising near the east prime vertical, and again, by moving the instrument in azimuth, near the west prime vertical when descending. The middle time will be the meridian passage of the star by the time-keeper, which, when compared with the computed right ascension, will show the error of the time-keeper. This method (commonly called that of *equal altitudes*) is not to be recommended, except for stars near the zenith, which pass quickly from one prime vertical to the other. The changes of the level, of the instrument, or of the time-keeper, may occasion greater errors than can well arise from the divisions of the circle, not to mention the greater length of time occupied by the observation and the chance of disappointment from change of weather. Lastly, the time may be derived from this instrument, when the lower circle is clamped, and the telescope is made to move in the meridian like a transit. The transit will be explained hereafter, but the adjustment to the meridian is greatly facilitated in this instrument by the divided horizontal circle. Either the azimuths of a star may be observed when it has the same altitude on the east and west of the meridian, in which case the middle reading of the azimuths will be the reading corresponding to the meridian; or the time may be got very nearly from a star near the zenith, and then the error of the time-keeper being known, Polaris or any near circumpolar star may be bisected, by moving the instrument in azimuth, at the time when, by the clock, it should be on the meridian; or Polaris, or any known circumpolar star, may be observed at its greatest elongation, when its azimuth is known by computation; or, generally, a known circumpolar star may be observed anywhere, and its azimuth be computed for the *known* time of the observation, when the instrument can be shifted this quantity. For the mode of correcting errors of level, &c., and of deducing the longitude from the passage of the moon over the meridian, &c., see TRANSIT.

When the direction of the meridian is required with great accuracy, the process used in the *Trigonometrical Survey*, vol. i., p. 242, may be followed. The azimuth of Polaris was observed when at its greatest elongation to the east and to the west of the meridian, and the mean of these was taken for the reading of the north point. The cross level should be applied to the transit axis and the error carefully noted before every observation, and the instrument should be reversed once at least during the series.

Little has been said of the *error of collimation in altitude*, because in truth the determination of this error is scarcely ever required in a separate shape by an accurate observer. It may, however, be determined thus. Observe a star with the divided face of the circle to the east, and then with face west, near the meridian, exactly as has been already described, correct each zenith distance to the meridian and for the indication of the fixed level. Then the difference between these zenith distances, if any, shows that the microscopes do not read 0°, when the telescope is in the zenith and the vertical axis is correct: half the difference is to be added to all observations made with the instrument when the face is one way, and to be subtracted from all observations when the face is the other way, as the case may be.

If an observer should wish to use an instrument of this kind for making a catalogue of unknown stars, he may place it accurately in the meridian, and observe transits and zenith distances at once, using an index error for the latter deduced from known or standard stars, as we have described above. Or the zenith distances may be determined by *circum-meridian* observations, which is perhaps a more accurate and certainly a more independent mode. The peculiar advantage of the altitude and azimuth circle is however for observing phenomena when out of the meridian, and therefore not within the reach of the principal instruments: for instance, in determining the place of a comet, &c. Here the time must be noted when the object is bisected by the crossing of the horizontal and vertical wires, and the upper and lower microscopes and fixed level read off. The instrument is now to be reversed and the operation repeated. Then if the object is not near the meridian and the interval is short, the mean of the zenith distances and the mean of the azimuthal readings correspond very nearly to the middle time, and as the azimuthal reading of the meridian is, or easily may be known, the azimuth and zenith distance of the object at a *given* time are known, which, with the colatitude, are two sides, and the included angle of the triangle Z P S, which can therefore be solved, and the polar distance P S, and the horary angle Z P S be found. If the observations should be made near the meridian, the corrections as found in circum-meridian observations must be applied.

---

[*] Let S be the first star observed near the meridian, and s the second near the prime vertical, P the pole, and Z the zenith; then PZ the colatitude = PS − ZS nearly. Again, the triangle PZs being solved with this approximate value of PZ will give the angle sPZ, which, if the star is west, being added to, or if east, being subtracted from its right ascension computed from the catalogued place, gives the true sidereal time at the place of observation, and hence the error and correction of the time-keeper. Let this correction be applied to the time of observing S, then the difference between the time so corrected and the computed right ascension of S gives the ∠SPZ, from which the correction of ZS to the meridian may be deduced.

The observer, who is not afraid of working spherical trigonometry, will find the following a very exact method of ascertaining the place of a comet or planet. Observe the altitude and azimuth, noting the time, of a known star, as near the comet as may be, and then the altitude and azimuth, also noting the time, of the comet. The *computed* altitude and azimuth of the star, when compared with that *observed*, will give an index error for the instrument, in altitude and in azimuth; which, when applied to the observed places of the comet, afford correct data for computing its horary angle and polar distance. This method is only an application of the principle of measuring differences, rather than absolute quantities, and admits of great exactness, even with an indifferent instrument, especially if several stars, on different sides of the comet, are used; but the labour is considerable.

An instrument of this kind will show very clearly the effects of refraction and parallax, though it cannot be expected to increase our knowledge on these points. On comparing the observed zenith distance with the zenith distance computed from the polar distance, and the horary or azimuthal angle, the difference will be the effect of refraction, or of refraction and parallax, as the case may be. The determination of the law and quantity of refraction was one of the purposes for which Piazzi's circle was principally designed.

The instrument-maker ought to mark the value of the parts on the scales of the levels, but it is advisable to ascertain these independently. Place the instrument so that the third foot-screw, that with the slow motion apparatus, is in the plane of the altitude circle, raise the foot-screw till the end of the bubble towards the observer is near the end of the scale, bisect a well-defined object with the telescope, and read the upper microscopes and the ends of the bubble. Then lower the foot-screw till the bubble is towards the other end of the scale, bisect the object again, and read off the microscopes (bringing the crosses to the same divisions) and bubble as before. You have thus a given number of parts of the scale, those through which the bubble has travelled, equal to the difference of the readings of the microscopes in the two positions, which is therefore known in seconds of space. This should be done several times and the temperature noted, as it will be found that not only the length of the bubble, but the value of the parts, varies with the temperature. A table may then be made for future use. By attaching the cross level to the altitude circle it may be examined in the same way.

There are several variations in the form of the altitude and azimuth circle. The vertical axis is sometimes depressed below the azimuth circle, which gives the instrument a greater compactness of form. In a few instances, instead of a pair of microscopes upon a fixed support, there are three or more which can be placed anywhere on the circumference of a ring, parallel to and concentric with the vertical circle. This is a very essential improvement, as besides getting rid of eccentricity, three microscopes at 120° distance, or a pair at right angles, destroy the effect of any change of figure corresponding to ellipticity. (See *Monthly Notices of the Astron. Soc.*, vol. ii., p. 96.) The errors of division may also be gradually eliminated by changing the positions of the readings. Three or more microscopes are sometimes applied to the horizontal circle.

The circle here drawn and described is divided by an engine; in instruments of higher pretensions one or both circles are divided by hand, generally according to Troughton's method. Sometimes both faces of the vertical circle are divided. There is a figure and description of a very beautiful circle, generally known by the name of the Westbury Circle, in a paper by Mr. Pond, *Phil. Trans.*, 1806, p. 420, plate xx., and of another in *Pearson's Astronomy*, vol. ii., p. 434, plate xix. A vertical circle, of eight feet diameter, moving freely in azimuth, planned by Ramsden and finished by Berge, is at the Observatory of Dublin, which, so far as we know, has not yet been described, though well known by the deductions of Dr. Brinkley. (See *Trans. Royal Irish Academy*, vol. xii., p. 33.)

The *transit circle* is very shortly described, as it is only the upper circle of the last-mentioned instrument, generally on a larger scale. This, when fixed in the plane of the meridian, may be used both as a transit and as a meridian circle at the same time. The supports should be of stone, to which the reading microscopes should also be attached. A very beautiful transit circle, of four feet diameter, and divided on both faces, was constructed by Mr. Troughton in 1804. This was for many years in the possession of the late Stephen Groombridge, Esq., of Blackheath, and was employed by him in forming a catalogue of stars within 50° of the north pole. It is described and engraved in *Pearson's Astronomy*, vol. ii., p. 402, plate xvii. The artist himself was dissatisfied with the weakness of the axis, a capital fault in an instrument for observing transits, and we conceive that there was a still greater oversight, though one more easily repaired, in the unsteady fixing of the reading microscopes, which are mounted on slender bars of brass instead of stout stone crosses; the consequence was, that the index error was always changing. The meridian circle of Roemer, and those which resemble it, have been already mentioned. This form is perhaps preferable to that of Groombridge's, the axis being less subject to flexure; but its unsymmetrical appearance is disagreeable, and makes some of the ordinary modes of adjustment impracticable. The unequal bearing on the pivots may also require caution. The meridian circle of Reichenbach is like the ordinary transit telescope, with the circle and verniers close to one of the pivots. It is too complicated to be described in a few words, and is not, we believe, to be met with in this country; but most of the continental observatories east of the Rhine are furnished with them. In the hands of Bessel, Gauss, &c., the circle of Reichenbach is undoubtedly a very powerful and accurate instrument, but we think not so perfect, certainly not so fit for ordinary observers, as a closer copy of Röemer's would be, while it is much less simple, and the telescope is more liable to injurious flexure.

The adjustments of the transit circle are those of a mural circle and of a transit combined. A very ingeniously contrived plumb-line was applied to Groombridge's circle, to level the cross axis and adjust the collimation in altitude, but the methods already described were found to be more accurate and much less troublesome. Indeed the plumb-line apparatus of the mural circle is superseded by the use of observations by reflection.

Besides the works we have already referred to, the astronomical reader may consult, as to the mural circle, Pond's *Observations*, 1812, p. 236, and 1825 (where an example is fully worked out), for an account of his two methods, and his memoirs in the *Phil. Trans.* and *Memoirs of the Astronomical Society*; *Cambridge Observations*, vols. vi. and vii., and Johnson's *Catalogue of Southern Stars*, 1835. For the transit circle, Wollaston's *Fasciculus*, Preface and Appendix. For the altitude and azimuth circle, a Paper by Mr. Troughton, *Memoirs of the Astron. Society*, vol. i. p. 33; and generally the article *Circle* of the *Edinburgh Cyclopædia*, by Mr. Troughton, and Dr. Pearson's *Practical Astronomy*. On the mode of dividing circles and the errors to which their divisions are liable, see Graduation, and Troughton's *Memoir*, *Phil. Trans.*, 1809, p. 105; Dr. Robinson's Paper, already cited, and another by the same author, *Memoirs of the Irish Academy*, 1825; two Papers in the *Memoirs of the Astron. Society* on the *Errors of the Cape Circle*, one by Mr. Sheepshanks and Professor Airy, vol. v., p. 320; the other by Mr. Henderson, vol. viii., p. 141.

CIRCLE, MURAL. [Circle, Astronomical.]

CIRCLE, REFLECTING. [Sextant.]

CIRCLE, REPEATING. [Repeating Circle.]

CIRCLE, TRANSIT. [Circle, Astronomical.]

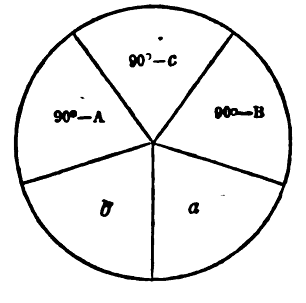
CIRCLE (QUADRATURE of the). [Quadrature.]

CIRCLES OF DECLINATION, ALTITUDE, &c. The use of these terms is not very well settled. According to some, a circle of declination would mean the parallel of any declination, or the small circle all whose points have the same declination; that is, a parallel to the equator. According to others, it would mean the circle on which declination is measured, that is, an *horary* circle passing through the poles. And the same of the other circles. Perhaps the latter sense is the more generally used; but in all cases the student must be aware of the difference when he consults a book on the doctrine of the sphere.

CIRCUITS, in English law, denote the periodical progresses of the judges of the superior courts of common law through the several counties of England and Wales, for the purpose of administering civil and criminal justice. The ordinary circuits take place in the spring and summer of each year; and for several years past one of the judges has made a circuit through the counties of Hertford, Essex, Kent, Sussex, and Surrey, in the month of December, for the trial of criminals. All the circuits take place under the authority of several commissions under the great seal, issued to the judges and others associated with them on each occasion. [ASSIZE.] Most barristers practising in the common law courts in London are attached to one or other of the circuits; and each circuit is constantly attended by a numerous bar. The transaction of judicial business in the presence of a professional audience of this kind, has been justly considered as one of the best securities for the due administration of justice; and in consequence of the system of circuits, this advantage is not confined to the metropolis, but is communicated to the most remote parts of the kingdom.

Since the statute 11 Geo. IV., and 1 Will. IV. c. 70, by which the ancient system of Welsh judicature was abolished, the circuits of the judges are eight in number, and the counties of England and Wales are distributed among them in the following manner. The Northern Circuit comprehends the counties of York, Durham, Northumberland, Cumberland, Westmoreland, and Lancaster; the Western Circuit comprehends the counties of Southampton, Wilts, Dorset, Devon, Cornwall, and Somerset,—and Bristol; the Oxford Circuit comprehends the counties of Berks, Oxford, Worcester, Stafford, Salop, Hereford, Monmouth, and Gloucester; the Midland Circuit comprehends the counties of Northampton, Rutland, Lincoln, Nottingham, Derby, Leicester, and Warwick; the Home Circuit comprehends the counties of Hertford, Essex, Kent, Sussex, and Surrey; the Norfolk Circuit comprehends the counties of Buckingham, Bedford, Huntingdon, Cambridge with the Isle of Ely, Norfolk, and Suffolk; the South Wales Circuit comprehends the counties of Glamorgan, Carmarthen, Pembroke, Cardigan, Brecon, Radnor, and Chester; the North Wales Circuit comprehends the counties of Montgomery, Merioneth, Carnarvon, Anglesey, Denbigh, Flint, and Chester.

CIRCULAR PARTS (NAPIER'S). A proposition which generalizes the relations between the parts of a spherical right-angled triangle into two only; first given (with a demonstration) by Napier in his 'Mirifici Logarithmorum Canonis Descriptio' (ch. iv., 1—8). It is as follows: Let a and b be the sides, c the hypothenuse, and A and B the angles opposite a and b, in a right-angled spherical triangle. Then take the complements of the hypothenuse and of the two angles, and the two sides, and write them in order in a perpetually recurring series, or round a circle, as follows:



Then taking any three parts, one may be made the *middle* part, and the other two either *adjacent* extremes, or *opposite* extremes. Thus 90°—B being the middle part, a and 90°—C are its adjacent extremes, and b and 90°—A its opposite extremes. Napier's rules are

1. Sine of *middle* = product of tangents of *adjacents*.
2. Sine of *middle* = product of cosines of *extremes*.

$$\text{Thus sin. } b = \text{tan. } a \text{ tan. } (90° - A)$$
$$= \text{cos. } (90° - B) \text{ cos. } (90° - c).$$

But we should strongly recommend the student to have nothing to do with this artificial memory, for it involves a process upon every occasion; and while one person is learning which are the parts, which have complements taken, and the rules, another will master the six results, and will have no occasion for any future process. These results are

1. Cosine of hyp. = product of cosines of sides.
2. Cosine of hyp. = product of cotangents of angles.
3. Sine of *side* = sine of hyp. × sin. *opposite* angle.
4. Tang. of *side* = tang. of hyp. × cos. *adjacent* angle.
5. Tang. of *side* = tang. *opposite* angle × sine of other side.
6. Cos. of *angle* = cos. of *opposite* side × sin other angle.

These pairs present analogies which will help the memory, and we should recommend them in preference to the rules of circular parts.

CIRCULATING DECIMALS. When a common fraction cannot be expressed exactly as a decimal, the attempt leads to a never-ending series of figures, any number of which, with the decimal point properly placed, is an approximation to the common fraction, and the more near the greater the number of figures taken. Thus 1 with ciphers affixed and divided by 7, leads to the recurring or circulating series

142857142857142857......

and ·1428 is nearly $\frac{1}{7}$, but ·14285714 much more nearly. Hence it is said that $\frac{1}{7}$ is a circulating decimal whose period is 142857, and is denoted by $\cdot\dot{1}4285\dot{7}$. Similarly $\cdot 12\dot{9}$ denotes ·129999.... and $\cdot 05\dot{3}\dot{6}$ denotes ·053636.... As a part of practical arithmetic, the rules for converting these fractions into common fractions are useless, though found in most elementary works. One example will be sufficient here.

$$\cdot 14\dot{3}6\dot{2} = \cdot 14362362, \&c. = \cdot 14 + \tfrac{1}{100} \times \cdot 362362....$$

If the circulating part continued *ad infinitum* be called S, it is plain that $1000\ S = 362 + S$, or $S = \frac{362}{999}$, whence

$$\cdot 14\dot{3}6\dot{2} = \frac{14}{100} + \frac{362}{99900} = \frac{14 \times 999 + 362}{99900}$$

Wallis (*Algebra*, ch. 89), Euler (*Algebra*, ch. 12, book i.), and John Bernoulli the second (*Mem. Acad. Sci.*, 1771), have treated this subject. We shall merely state some theorems to show the remarkable character of the periods.

1. Form the period of a prime number m; its number of figures will be either $m - 1$ or one of its divisors. The period of 7 (being 142857) has six figures; that of 13 (being 769230) has 6, the half of 13 − 1 figures.

2. When the period of a prime number m contains $m - 1$ figures, the last half may be formed from the first by taking each figure in the first from 9. Thus the first and second halves of the period belonging to 47 are—

First half	02127659574468085106382
Second half	97872340425531914893617

3. When the period of a prime number m has $m - 1$ figures, multiplication by any number under m only changes the order of the figures. Thus the period of 7 being 142857, we have here a number which, being multiplied by 2, becomes 285714; by 3, 428571; by 4, 571428; by 5, 714285; and by 6, 857142.

The following work may be useful to those who are curious on the subject: 'A Table of the Circles arising from the division of a Unit, or any other whole number, by all the integers from 1 to 1024, being all the pure decimal quotients that can arise from this source.' London, Richardson, 1823.

CIRCULATION OF THE BLOOD. The constitution of the blood, the nutrient fluid of the animal body, has been already described. Since the blood is necessary to nourish all the tissues of the body and to stimulate all its organs [BLOOD], it must be in motion in order to be borne to them. 'In man and in all the higher animals an apparatus is provided, partly for the purpose of originating an impelling force to put the blood in motion, and partly for the purpose of conveying the blood when put in motion to the different parts of the body.'

The organ that puts the blood in motion is the heart; the pipes or conduits which distribute the blood to the different parts of the body are the great vessels in connexion with the heart. The course of the circulation, which in all the higher animals is double—viz., one through the lungs, called therefore the *pulmonic*, or the *lesser circulation*; the other through the system, called therefore the *systemic*, or the *greater circulation*—cannot be understood until the structure and action of the heart have been explained.

[Heart, and its Great Vessels.] In the mean time it will be sufficient to state in this place the evidence that the blood is really in motion. The author of the 'Philosophy of Health' thus sums up the proofs that the blood is a flowing stream, and that it constantly pursues a regular and determinate course.

'1. With the microscope, in the transparent parts of animals, the blood can be seen in motion; and if its course be attentively observed, its route may be clearly traced.

'2. The membranes, termed valves, are so placed as to allow of the freest passage to the blood in the circle described; while they either altogether prevent, or exceedingly impede its movements in any other direction.

'3. The effect of a ligature placed around a vein and an artery, and of a puncture made above the ligature in the one vessel and below it in the other, demonstrates both the motion of the blood and the course of it. When a ligature is placed round a vein, that part of the vessel which is most distant from the heart becomes full and turgid, on account of the accumulation of blood in it; while the part of the vessel which is between the ligature and the heart becomes empty and flaccid, because it has carried on its contents to the heart and it can receive no fresh supply from the body. When, on the contrary, a ligature is placed round an artery, that portion of the vessel which lies between the ligature and the heart becomes full and turgid, and the other portion empty and flaccid. This can only be because the contents of the two vessels move in opposite directions—from the heart to the artery, from the artery to the vein, and from the vein to the heart. At the same time, if the vein be punctured above the ligature, there will be little or no loss of blood; while if it be punctured below the ligature, the blood will continue to flow until the loss of it occasions death; which could not be unless the blood were in motion, nor unless the direction of its course were from the artery to the vein, and from the vein to the heart.

'4. If fluids be injected into the veins or arteries, whether of the dead or the living body, they readily make their way and fill the vessels, if thrown in the direction stated to be the natural course of the circulation; but they are strongly resisted if forced in the opposite direction.'

The author concludes his account of the structure of the heart and blood vessels, and of the course which the stream of blood is ascertained constantly to pursue, with the following reflections:

'Such is the description, and, with the exception of the first proof, such the evidence of the circulation of the blood in the human body, pretty much as it was given by the discoverer of it, the illustrious Harvey. Before the time of Harvey, a vague and indistinct conception that the blood was not without motion in the body had been formed by several anatomists. It is analogous to the ordinary mode in which the human mind arrives at discovery (chap. iii., p. 103), that many minds should have an imperfect perception of an unknown truth before some one mind sees it in its completeness, and fully discloses it. Having about the year 1620 succeeded in completely tracing the circle in which the blood moves, and having at that time collected all the evidence of the fact, with a rare degree of philosophical forbearance, Harvey still spent no less than eight years in re-examining the subject and in maturing the proof of every point, before he ventured to speak of it in public. The brief tract which at length he published was written with extreme simplicity, clearness, and perspicuity, and has been justly characterized as one of the most admirable examples of a series of arguments deduced from observation and experiment that ever appeared on any subject.

'Contemporaries are seldom grateful to discoverers. More than one instance is on record, in which a man has injured his fortune and lost his happiness through the elucidation and establishment of a truth which has given him immortality. It may be that there are physical truths yet to be brought to light, to say nothing of new applications of old truths, which, if they could be announced and demonstrated to day, would be the ruin of the discoverer. It is certain that there are moral truths to be discovered, expounded, and enforced, which, if any man had now penetration enough to see them, and courage enough to express them, would cause him to be regarded by the present generation with horror and detestation. Perhaps during those eight years of re-examination the discoverer of the circulation sometimes endeavoured in imagination to trace the effect which the stupendous fact at the knowledge of which he had arrived would have on the progress of his favourite science; and, it may be, the hope and the expectation occasionally arose, that the inestimable benefit he was about to confer on his fellow-men would secure to him some portion of their esteem and confidence. What must have been his disappointment when he found, after the publication of his tract, that the little practice he had had as a physician by degrees fell off? He was too speculative, too theoretical, not practical. Such was the view taken even by his friends. His enemies saw in his tract nothing but indications of a presumptuous mind, that dared to call in question the revered authority of the antients; and some of them saw, moreover, indications of a malignant mind, that conceived and defended doctrines which, if not checked, would undermine the very foundations of morality and religion. When the evidence of the truth became irresistible, then these persons suddenly turned round and said that it was all known before, and that the sole merit of this vaunted discoverer consisted in having circulated the circulation. The pun was not fatal to the future fame of this truly great man, nor even to the gradual though slow return of the public confidence even during his own time, for he lived to attain the summit of reputation.'

In the seventh chapter of the *Philosophy of Health*, from which the above extract is taken, will be found a full account of the apparatus of the circulation, of the powers which move the blood, and of the uses which the circulation accomplishes in the living economy. [Heart, and its Great Vessels.]

CIRCUMCISION, the operation of cutting off the prepuce or foreskin, is sometimes performed for a medical purpose; but it is general or universal among some nations as a religious rite, and among others as a national custom. The practice of circumcision appears to be of the highest antiquity. Abraham, as recorded in *Genesis* (xvii. 10-15), by the command of God, circumcised himself and all the males of his household. Abraham himself was ninety-nine years old (*Gen.* xvii. 24) when he was circumcised. The rite of circumcision was ordained to be an everlasting covenant between God and the seed of Abraham; and it was declared that 'the uncircumcised man-child whose flesh of his foreskin is uncircumcised, that soul shall be cut off from his people; he hath broken my covenant.' All the males that left Egypt were circumcised, but during the forty years' wandering in the wilderness the rite was not performed. Joshua, by the express command of God, renewed it by circumcising all the males just after the passage of the Jordan. (*Joshua*, v.) Ever since the circumcision by Joshua, it has been universally observed, both among the Jews and the Ishmaelitish descendants of Abraham. Circumcision is not, properly speaking, a rite of the Mohammedan religion; it is not enjoined in the Koran, but the Arabs and Mohammed himself were circumcised before the religion of the Koran began to be preached, and their descendants have continued the usage as one which had always prevailed among them, and have also communicated it to the Saracens, the Turks, and the other nations who have become associated with them in a common faith. In point of fact, circumcision is as universal among the Mohammedans as it is among the Jews.

A great deal has been written, both on the ceremonial of the Jewish circumcision and on the question as to the sacramentary efficacy which has been sometimes attributed to the rite. On these matters the reader may consult Burder's 'Oriental Literature,' Calmet's 'Dictionary of the Bible,' Simon's 'Dictionary of the Bible,' and especially the able dissertation on circumcision in Michaelis's 'Commentaries on the Laws of Moses,' book iv., chap. iii., part i., articles 184—186, English translation by Dr. Smith, 4 vols. 8vo., 1814, and the authorities there referred to. Michaelis is decidedly of opinion that circumcision was never intended as a sacrament. Among the antient Jews, not only all proselytes were circumcised, but also all bondmen or slaves, and their children (*Gen.* xvii., 12, 13): 'He that is born in thy house, and he that is bought with money of any stranger, which is not of thy seed: he that is born in thy house, and he that is bought with thy money, must needs be circumcised.'

The prevalence of circumcision among various antient nations is mentioned by Herodotus (ii., 36, 37, 104), by Diodorus Siculus (i., 26 and 55, iii., 32), and others. Herodotus says that the Colchi, the Egyptians, and the Ethioptians, were the only nations who had practised it from time immemorial, and that the Phœnicians and the Syrians of Palestine (the Jews) admitted that they had acquired the custom from the Egyptians. This notion, that the Jews had learned circumcision from the Egyptians, has been taken up and maintained in modern times by Sir John Marsham in his 'Chronicus Canon Ægyptiacus,' and others. (See De Pauw's *Recherches Philosophiques sur les Americains*, tom. ii., pp. 117—150; and a note of Gibbon's to the 47th chapter of his history.) But supposing this opinion to be false, it does not follow, on the other hand, as has been contended by some, that all other nations among whom the custom prevails must have derived it from the Jews. It has been supposed by some critics (but in our opinion without good reason), that among the antient Egyptians it was only the priests and those who desired to study the sciences of which they were the teachers, who were obliged to be circumcised. See the notes of Wesseling and Larcher on the passages of Herodotus above referred to, the Commentary of Origen on the 'Epistle to the Romans,' ch. ii., v. 13, and a curious note of M. Huet on Origen's Commentary on Genesis. (Origenis Opera, à Car. de la Rue, 4 vols. fol., Par., 1733, &c.; vol. ii., p. 16.) It is said that Pythagoras submitted to the operation of circumcision in order to obtain instruction in the secret doctrines of the Egyptian priests. (See, upon the origin of circumcision, a note on the 4th sect. of the 22d chapter of Volney's *Revolutions of Empires*.)

Strabo (book xvii., 824) says by mistake that the Jews practised excision on their female children; but, although this was never a custom of the Jews, it has prevailed, and still does, among other nations, particularly the Abyssinians, Nubians, and the modern Egyptians. See Ludolphi, 'Hist. Aethiopica,' iii., 1; Niebuhr's 'Description de l'Arabie,' pp. 67—71, and the 52d of the questions drawn up by Michaelis, pp. 105—109; Sonnini's 'Travels in Egypt,' Hunter's translation, vol. ii., pp. 29—38; 'Description de l'Egypte' (edit. of 1823), vol. xiii., p. 213; and especially Browne's 'Travels in Africa, Egypt, and Syria,' 2nd edit., pp. 394—400.

It is remarkable that circumcision has been found to prevail, and in some cases the excision of females also, among various savage or imperfectly-civilized races. It is said that the rite was practised by the Mexicans when the Spaniards first became acquainted with them. Cook found an imperfect species of circumcision, consisting of the slitting of the prepuce, in use among the natives of the Friendly Islands. (Kerr's *Voyages*, vol. xiii., p. 62.) Long before, many of the old voyagers had met with it among the islands of the Indian Archipelago, among the tribes of the west coast of Africa, and elsewhere. In Purchas's Collection, Edmund Scot gives a long account of the ceremonial of the circumcision of the king of Bantam in Java, at which he was present in 1605. Captain William Keeling, in 1608, states that he found the people at the bay of St. Augustine, on the west coast of Africa, circumcised; and Captain Richard Jobson describes the ceremony as he witnessed it at Batto, on the same coast, in 1621. An abstract of these and other early accounts may be found in Prevost's 'Histoire Générale des Voyages,' iii., 211, &c. See the same work (viii., 601) for a description of the ceremony of circumcision as practised among the people of Madagascar. Dampier, in his graphic manner, describes the mode of circumcision as he witnessed it performed in 1686 at the Philippine Islands. (*Voyages*, i., 339—343.) An account of what he calls the circumcision of females as well as of males by some of the African tribes is given by Bosman in his 'Description of the Coast of Guinea,' English translation, 2nd edit. pp. 179, 180, 329, 414. The principal distinction between circumcision as practised by the Jews and by other nations, is that the former, in obedience to the terms of the command given to Abraham, always when it is practicable circumcise the child on the eighth day after its birth; whereas, among other nations it is usually deferred to a much later period. Among the Mohammedans it is commonly performed in the thirteenth year, because Ishmael, the progenitor of the Arabs, was of that age when he underwent the operation. (*Gen.* xvii., 25.)

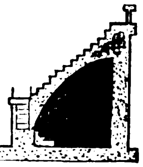
Kolben, in his 'Present State of the Cape of Good Hope' (translated by Medley, 2nd edit., i., pp. 112—119), gives an account of a very singular custom of the Hottentots, which he conjectures may have been derived from the Jewish circumcision.

Besides the authorities already referred to, the reader may consult the articles on circumcision in 'Hofman's Lexicon Universalis,' and in the 'Encyclopédie.' In the latter will be found an account of the opinions of both the Jewish rabbis and the Christian fathers on the doctrinal questions connected with the subject of circumcision. On the medical, including both the physical and moral, part of the subject, see Michaelis and Niebuhr, as already referred to; the *Encyclopédie, Art. Prepuce;* Bartholini's *Comment. de Morbis Biblicis;* and Drake's *New System of Anatomy*, 2nd edit., vol. i., pp. 127, 128.

CIRCUMFERENCE (*circum* and *fero*), the line which goes round a figure. We do not know why, but this word is always applied to a curvilinear figure; while the synonymous Greek word periphery (περί, φέρω) is used for a rectilinear figure.

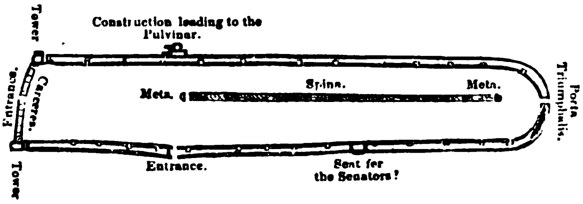
CIRCUMFLEX. [ACCENT.]

CIRCUS, a large enclosed space, adapted for chariot-races, an amusement to which the Romans were passionately attached. The name Circus (of which Circulus, a *circle*, is a diminutive) does not convey an exact idea of the form of this building, which both in its outline and its use very much resembled the Greek Stadium. There were many circi in Rome, of which the Circus Maximus and the Circus Agonalis were perhaps the largest. The former may still be distinctly traced; the latter retains its external form only in the Piazza Navona of Rome. The Circus Aurelianus, or, according to some, of Heliogabalus, stood near the Amphitheatrum Castrense. The ruins of the Flaminian Circus are hid beneath the pavement of the city. The Circus of Nero was begun by Caligula; part of its site is now occupied by the Basilica of St. Peter. This circus is said to have been longer than the cathedral and colonnade in front. (Fontana's *Tempio Vaticano*, p. 245.) Another circus, begun by Nero, and finished by Hadrian, was situated in the gardens of Domitia, near the Mausoleum of Hadrian. Several antiquities and paintings were discovered here a few years ago. In the Gardens of Sallust there was a fine circus, which was also adapted for the exhibition of naumachiæ. The Circus of Flora was on the Quirinal Hill. There is a circus, not far from the Appian Way, near the tomb of Cæcilia Metella, about two miles from Rome, in a high state of preservation. It is probably of a later date than many of those which were constructed within the city; and perhaps to the circumstance of its being at a distance from the city walls, its present state of preservation may principally be owing. Antiquaries have called it the Circus of Caracalla, although no proof, we believe, has been discovered from inscriptions that this is the circus built by, and commemorated on the coins of, that emperor.



Section of Seats.

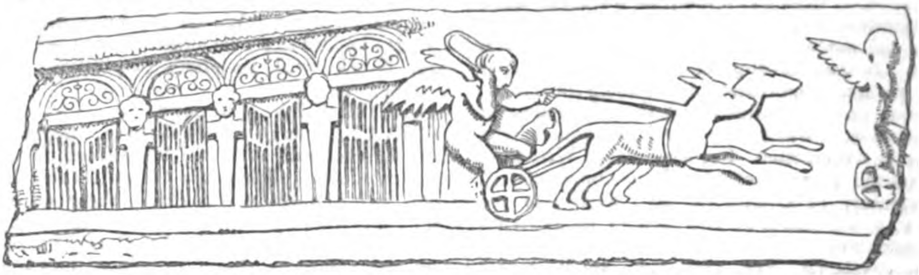
Amphora used in constructing the arch.



[Plan of the Circus of Caracalla.]

Bianconi makes the Circus of Caracalla 255 French toises long, and 50 toises wide: the spina 142 toises long, and the start from the carceres to the spina 79 toises The widths of the openings between the spina and the walls of the circus are 21·3 toises at the first goal. 19·3 at the second goal, 17 toises at the turn on the other side of the second goal, and 15·4 toises at the final goal. The width of the vaulting is 4 toises. (A toise is about 6·396 English feet.)

The Circus of Caracalla, of which we have given a plan and a section of the seats, may be considered a perfect model of this kind of building, both in judicious arrangement and ingenious construction. The long sides are not quite parallel: one end is semicircular, and the carceres at the opposite end, from which the chariots started, are formed on a segment of a circle, the chord of which is inclined to the long sides of the circus. The spina, or raised division, which runs along the middle of the circus, is a kind of podium or basement, in appearance like a thick dwarf wall. It is not exactly parallel to either side of the circus. Of the carceres, which are twelve in number, six are placed on each side of the entrance which was intended for the use of the processions, and are so disposed, by the inclination of the chord line of the segment on which they may be said to be set off, that the starting of the twelve chariots was equalized. The carceres were most probably covered; they were also divided by partition walls with terminal figures in front of them, and arched over, with a cornice above the arches: the semicircular opening was filled with a window frame of marble, highly enriched; and they were closed with gates, most probably of bronze. A very tolerable idea of the architectural appearance of a Circus may be formed from the inspection of a bas-relief in the British Museum.



There is also a representation of a marble fragment in Bianconi's work on this circus, in which men are seen opening the bronze gates, in order, as we may judge from their hurried action, to let out the chariots at the given signal. The spina, which was rounded at the two extremities, was decorated with metæ, or goals, each formed of three long cones.* The eggs were placed on the apex of each cone. Dolphins were also employed for this purpose: these cones were sometimes gilt. In the basement of the cones in the Circus of Caracalla there is a small chamber formed; and the basements are separated from the spina. In the centre of the spina there was sometimes one of those enormous obelisks which were brought by the emperors from Egypt. Previous to the time of Augustus, a long pole occupied the centre. Small temples, statues, columns with statues on their summits, and altars, adorned the intermediate spaces between the centre and the goals; so that the spina must have presented a highly decorated and very beautiful appearance. The Porta Triumphalis, or gate by which the victor left the circus, was at the end opposite to the carceres. It is not improbable that the pulvinar, or emperor's seat, which, in the Circus of Caracalla, was a loggia with columns, was constructed at that part of the circus where the emperor, being near the carceres, would have the best view of the start and of the arrival at the goal. At the ends of the carceres of the Circus of Caracalla were two towers, in one of which is a staircase leading to the roofs of the carceres. The people occupied the stone seats along the sides and at the semicircular end of the circus. The Euripus, a canal ten feet wide and ten deep, was formed as a protection to the spectators, when they were not separated from the open space by a high podium or basement. The Circus of Caracalla has the podium and no Euripus. Some notion of the appearance of the circi may be collected from the medals of Caracalla and Trajan. In these medals the metæ and the quadrigæ are discernible, and the obelisk in the centre of the spina.

* See a representation of these cones in the Library of Entertaining Knowledge, Townley Gallery, vol. I., p. 141.

In order to lighten the weight of the materials used in the construction of the arch which supports the seats of the Circus of Caracalla, large amphoræ have been employed in the crown of the arch. Under this archway the people passed to the various openings with steps which led to the seats. The archway formed one great vomitorium. Although there were twelve carceres, the number of chariots varied: in a representation of a chariot-race on a sepulchral monument at Foligno, nine are represented.

The Circus Maximus, which was situated in a valley between the Palatine and Aventine hills, was very similar in form to that of Caracalla. It is stated, in the *Encyclopédie Méthodique*, to be 2345 feet 6 inches in length, by 1029 feet 7 inches wide; but, according to Venuti, it is only 210 French toises long by 85 wide; that is, 1343·160 feet by 543·2. To Tarquinius Priscus tradition assigned the first building of a circus, on the site of which the Circus Maximus was afterwards erected. If ever there was a Circus of Tarquin, it may have been rebuilt after the destruction of the city by the Gauls. This edifice, whatever may have been its origin, was enlarged by Cæsar, and embellished by Augustus and Tiberius. In the time of Nero it was burnt down (Tacit. *Annal.*, xv., 35); Trajan repaired it; and under Antoninus it became partially ruined, but was afterwards restored. The exterior of the circus, except at the carceres, consisted of two stories, adorned with columns, and finished with a terrace. The ground floor was occupied by merchants, except on the days appointed for the games. There were four towers more in the Circus Maximus than in that of Caracalla; one in the centre over the carceres (equidistant from those at each end of the carceres), one over the principal entrance, and one at each end of the semicircle, where it joined the straight sides of the circus: these towers were crowned with quadrigæ. The spina, which was rather more than eight feet high and twelve broad, was decorated with temples in miniature, statues, and obelisks. Augustus brought an obelisk from Egypt, 126 feet high, and placed it in this circus; Constantius also erected in the circus the obelisk now called the Lateran, which is the largest of all the Roman obelisks.

There are traces of a circus at Tarragona, at Merida, at Murviedro (the ancient Saguntum), all in Spain; also at Nismes, Milan, Antioch, at Constantinople, and other places.

For some curious information concerning the Circus of Caracalla, see the Cavaliere Bianconi's work on that building; *Plan of Rome*, published by the Society for the Diffusion of Useful Knowledge; Nardini's *Rome*; *Encyclopédie Méthodique*, 'Architecture;' *Topografia delle Antichità de Roma*, dell'Abate Ridolfino Venuti.

The games, which derived their name, *ludi Circenses*, from the circumstance that, after the time of Tarquinius, they were celebrated in the circus, were, according to tradition, instituted by Romulus under the name of Consualia (Livius, i. 9), in honour of the god Consus (or Neptune). They were exhibited on various occasions and for various purposes; sometimes, for example, by magistrates and sometimes by private citizens; either as rejoicings for success in war, or to avert the anger of some god. A grand procession from the capitol to the circus opened the games, and the images of the gods were taken along in carriages (*thensæ*). The combatants, dancers, musicians, and others followed, and last of all the consuls and priests advanced to perform the sacred rites. The exhibition consisted chiefly of chariot and horse races. The charioteers were divided into four classes, distinguished by the colour of their dress; one was white, another red, another sky-coloured, and another green. Domitian added two more, the golden and the purple. The favour of the people to one class or another was determined quite as much by the dress as by the skill displayed. Serious consequences often followed the disputes on the superiority of one colour above another. The order in which the chariots stood was determined by lot; and the signal for starting was given by dropping a cloth (*mappa*, or *pannus*). The chariot which first ran seven times round the course was victorious, and the driver, after being proclaimed by the herald, was crowned with a palm-wreath, and received a considerable sum of money. There were usually twenty-five such heats in the course of a day. Contests in the five exercises (*quinquertium*, the Greek πενταθλον), running, leaping, boxing, wrestling, and throwing the discus, also formed part of the exhibition. Wrestlers were anointed with ointment by slaves: boxers used gloves strengthened with lead or iron to give force to their blows; all underwent a preparatory training and dieting. These exercises were performed by the combatants almost entirely naked, and hence were called sometimes *certamen gymnicum;* the combatants had only a slight covering round the middle. A mock-fight, called *ludus Trojæ*, was performed by young noblemen on horseback; an exhibition which was revived by Julius Cæsar. (Virgil, *Æn.* v. 561.) A sea-fight (*naumachia*) was sometimes represented: Domitian afterwards built a sea-fight theatre. (Suetonius, *Domit.* c. 5.)

The exhibition of the wild beasts (*venatio*) was one of the most attractive parts of their public entertainments. Wild beasts fought either with one another or with men; and the men were either forced to this combat as a punishment, or were induced to enter it by hire. Great expense was incurred to provide beasts for this exhibition, and they were collected from the most remote parts of the empire. In the days of imperial splendour and profusion, the public exhibitions of Rome contained nearly every rare wild animal that western Asia and northern Africa could produce. The beasts were kept in inclosures (*vivaria*) till the time appointed for the show. The exhibitor of the games (*editor spectaculorum*) presided on a seat (*pulvinar*) at the south side of the building. So passionately fond were the people of these games, that the expression *Panem et Circenses*, 'Bread and the Circensian Games,' was commonly used to signify the two prime necessaries of life to the Roman populace. The crowds brought together by the games naturally attracted such persons as conjurers, jugglers, and fortune-tellers to the place, which is hence called by Horace (Sat. i. 6, 113) *fallax*, 'deceitful.' The splendour of the exhibition increased in the later times of the republic. P. Cornelius Scipio and P. Lentulus once exhibited sixty-three panthers, and forty bears and elephants (Livius, xliv. 18); and Pompey on one occasion is said to have exhibited five hundred lions (a number beyond all belief), which were all dispatched in five days. (Dion. Cass. xxxix. 38.) (Pitiscus, *Lexic. Antiquit. Roman.*; Dr. Adam's *Roman Antiquities*, p. 311, &c.)

CIRCUS. [FALCONIDÆ.]

CIRENCESTER, colloquially called Ciceter, is an antient market town and parliamentary borough in the S.E. part of the county of Gloucester, and in the hundreds of Crowthorn and Minety. The town includes five hamlets or tythings, Oakley, Wiggold, Spiringate, Barton, and Chisterton, and is about 84 miles W.N.W. from London in a straight line, and 17 miles S.E. from Gloucester. It is pleasantly situated on the river Churn, antiently the Corin, which joins the Thames at Cricklade; and hence, as a Roman military station, the place was called Corinium or Cornovium, and Corin Castra. Three Roman roads, the Fossway, the Ermin Street, and the Icknield Way, all met at Cirencester. A branch of the Thames and Severn Canal comes to the town. It was a place of considerable importance during the Roman occupation of Britain, when its walls, of which partial traces still exist, were two miles in circumference. During the Heptarchy it was successively included in the kingdoms of Wessex and of Mercia. A great number of Roman and Saxon antiquities have been, and continue to be, found in and near the town. In 879 it was stormed and taken by the Danes, and was the seat of a great council held by Canute. It was again stormed and completely dismantled in the civil war of Henry III. with the barons. Lords Surrey and Salisbury, in the reign of Henry IV., having promoted an insurrection for the restoration of Richard II., these noblemen, with several of their accomplices, were killed at a public-house in the town by the bailiff and a party of the inhabitants. Their heads were sent to London as a present to King Henry. A magnificent abbey for black canons was built in 1117 by Henry I., on the foundation of a college for prebendaries, which was established by the Saxons long before the Conquest. The revenue of this abbey at the dissolution of monasteries under Henry VIII. was 1051*l.* 7*s.* 1*d.* and its mitred abbot had a seat in parliament.

The town government is vested in two constables and fourteen wardsmen, elected annually. It has returned two representatives to parliament since the reign of Elizabeth. The borough is not incorporated: it is a polling place for the east division of the county. The living is a perpetual curacy, in the diocese of Gloucester. Cirencester had once three churches: that which still exists is a fine old structure of the fifteenth century, very elaborately ornamented externally and in the interior. Its embattled tower contains a peal of twelve bells. Cirencester is not a place of much trade; it has however an extensive clothing and a small carpet manufactory. Its appearance is that of a very respectable and opulent country town. Several streets of houses have been recently built, and others are in progress. The town is paved and lighted, and well supplied with water. It has a grammar-school, three endowed hospitals or almshouses, and several charitable institutions for education and other purposes: the total income of these charities is considerable. It has also an agricultural association, and annual races. The Baptists, Friends, Methodists, and Unitarians have chapels. Population of the parliamentary borough in 1831, 5240. Market-days Monday and Friday. Fairs on Easter Tuesday, on July 18, on Monday before and after Michaelmas, and on November 8, chiefly for agricultural stock and produce. In the vicinity is the handsome mansion of Oakley Park, the seat of Earl Bathurst. For a detailed historical and topographical description of Cirencester, see *Hist. of Cirencester*, by Rudder, 1800; Brayley and Britton's *Beauties;* and the *Histories of the County of Gloucester*, by Atkyns, Rudge, and Bigland.

CIRL BUNTING. [EMBERIZIDÆ.]

CIROLANA. [ISOPODA.]

CIRRATULUS. [DORSIBRANCHIATA.]

CIRRHIBA'RBA, a genus of fishes of the family Gobioides, and section Acanthopterygii. But one species of this genus is yet discovered, and this is from India. It has a tentaculum over each eye and nostril, three large tentacula at the end of the muzzle, and eight under the point of the lower jaw. These tentacula constitute the chief distinction between our present genus and that of Clinus, to which it is closely allied.

CIRRHI'GRADA. An order (the second) established by De Blainville for a small number of radiated gelatinous animals of the class *Arachnodermata*. Linnæus placed them among the *Medusæ*, to which they bear some external resemblance, but from which they differ, first, in having a transparent cartilaginous support, which sustains the dorsal disk of the umbrella of these creatures; and secondly, in having the proboscidiform stomach, which occupies the lower disk, accompanied by a great number of highly contractile and extensible tentaculiform cirrhi, very different from the appendages with which the *Medusæ* are supplied. De Blainville says that they have evidently more proximity to the tentacula of the *Actiniæ*, and perhaps even to the tentaculiform cirrhi of *Physalia* and the neighbouring genera; but that not having had an opportunity of studying the species except from individuals preserved in spirit, he is unable positively to decide on their natural position in the system, though he is led to regard them as approximating more to *Actinia* than to any other genus. He throws out a hint that the cartilaginous support may perhaps be regarded as a polyparium, and that it is, in fact, analogous to the calcareous part in *Cyclolites*, &c. Lamarck placed the genera among his *Anomalous Radiaria*, a section of his division of soft radiated animals (*Radiaires Molasses*), and next to the first genera of his *Radiaires Medusaires;* viz., *Eudora*, *Phorcynia*, *Carybdea*, &c. Cuvier arranges them under his *Simple Acalephans*, next to *Cestum*, observing that the two genera (*Porpita* and *Velella*) might form a small family in that order by reason of the internal cartilage which supports the gelatinous substance of their bodies. The following is De Blainville's definition of the order:—

Body, oval or circular, gelatinous, sustained in the interior of the dorsal disk by a solid subcartilaginous part, and provided on the lower surface of the disk with tentaculiform cirrhi, which are very extensible.

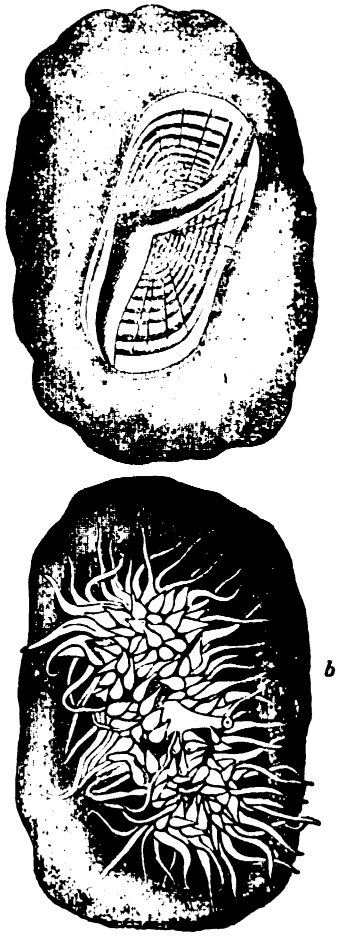
Genera. VELELLA.

Body membranous, oval, very much depressed, convex, swollen, sustained above by a transparent oval subcartilaginous piece, marked with concentric striæ, and surmounted by a vertical and oblique crest, concave below, with a sort of medial nucleus, offering a central mouth at the extremity of a proboscidiform prolongation, surrounded by tentacular cirrhi of two kinds, the external being much longer than the internal ones.

De Blainville observes that Imperato and Columna would appear to be the authors who first noticed the animals which constitute this genus, established, at first, under the name of *Phyllidoce*, by Patrick Browne, and figured by him in his 'History of Jamaica,' tab. 48, fig. 1. Forskahl, who gave a very good description of it, arranged it under his genus *Holothuria*. Lœfling made it a *Medusa*, denominating the species known to him *Medusa Velella*, a name adopted by Linnæus in the *Systema Naturæ*. Dana (*Soc. Roy. de Turin*, 1766) proposed the name of *Armenistarus* for it; and Lamarck published it under the generic appellation of *Velella*, by which it is now generally known to naturalists.

Geographical distribution, habits, and *use.*—This form is widely diffused, and has been found in the seas of Europe, America, Asia, and Australasia. The animals are met with far at sea, and often huddled together, young and old, in considerable masses. Sailors are said to fry and eat them.

Species.—The species (so called) are numerous; but De Blainville observes that he is far from admitting that they are sufficiently distinct; and, indeed, he well observes that he knows not on what characters the specific distinction should rest. Chamisso and Eisenhardt, apparently with good reason, were guided principally by the form of the cartilage and body, and the direction of the crest, and recognized three, confessing however that it had been impossible for them to compare their subjects rigorously with the species proposed by their predecessors. Eschscholtz describes ten, of which half are new, depending upon the form of the crest and the colour of the different parts. De Blainville however doubts whether they are really different. Example, *Velella lata.*



[Velella lata.]

a, upper side; *b*, lower side.

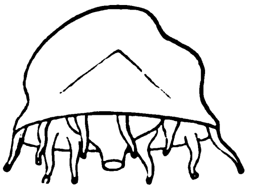
The following description, by Browne, of his *Phyllidoce labris cæruleis*, the *Sally-man*, which appears to be the *Velella cyanea* of Lesson and Garnot, and one at least of the species which give rise to the *Medusa Velella* of Linnæus and Gmelin (Lamarck quotes the last name as well as Browne's *Phyllidoce*, as synonyms of his *Velella* [illegible] *tira*) is worth recording as that of an eye-witness. By the help of the cuts the reader will readily understand the portion of his account which relates to the parts; but in Browne's figure there are no letters corresponding with the description: still however the notion of the position and motion intended to be conveyed will be understood without any very active exercise of the imagination.

'This insect,' says Browne, 'though evidently of this class, is more firm and opaque than either of the foregoing.' The Portuguese man of war is the animal whose description immediately precedes, 'and consists of an oblong, cartilaginous, flat body, slightly radiated from the centre, and intersected with small concentric lines: but this is furnished with two thin fleshy or semigelatinous lips *b b*, that extend themselves by short vermiform appendices over the under surface of the cartilaginous part. It is also supplied with a semi-elliptical, dry, transparent membrane E, which stands perpendicularly on the surface of the more firm part A, in the direction of the line D D, furnishing it with a pair of constant standing sails, which answer upon all occasions; for when this body is to move in any particular direction, suppose towards X, the part A D D, 1, of the perpendicular membrane, which arches in the direction of the line A D, 1 fills and pushes the body forwards, while the other part floats in the wind. But when the wind changes, and the body is to move towards Z, the other part answers in the same manner, and all the motions are performed by the same mechanism. It is furnished with a great number of slender tentacula, each about half an inch in length, which rise very thick from the margin of the cartilage underneath, and it seems to have an opening or mouth in the centre of the base.'

RATARIA.

Body oval, or circular, sustained by a subcartilaginous, compressed, elevated piece, with a muscular, movable, longitudinal crest above, concave below, and provided in the middle with a free proboscidiform stomach, and with a single row of marginal tentaculiform suckers.

Eschscholtz established this genus for some very small cirrhigrade animals, whose back is sustained by a subcartilaginous piece, not elevating itself in the dorsal cavity, and which only offer marginal cirrhi on the central surface. De Blainville, after observing that Forskahl has figured with his *Holothuria spirans* (*Velella limbosa* of Lamarck) some very small animals, which M. Eschscholtz himself regards as closely approximating to his *Rataria cordata*, says that it seems possible that the *Ratariæ* may be only degrees of development of *Velella*. Example, *Rataria mitrata*.



[Rataria mitrata, highly magnified.]

PORPITA.

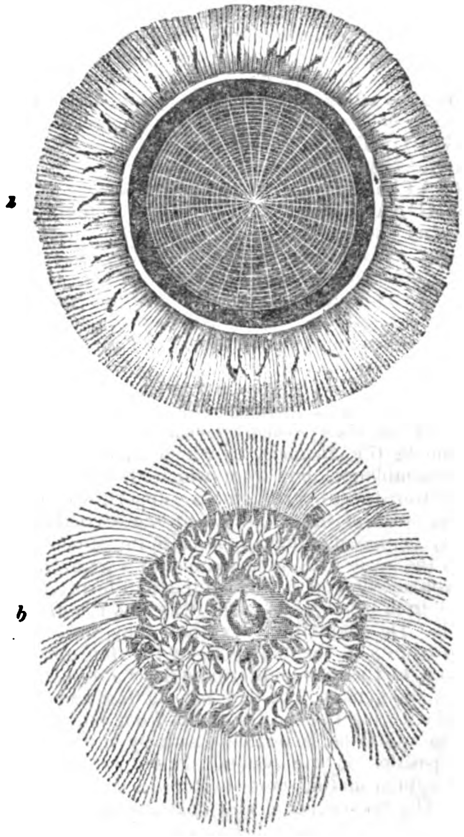
Body membranous, regular, circular, depressed, slightly convex above; internal cartilaginous support, circular, with its surface marked by concentric striæ crossing radiated striæ, covered on its upper surface by a delicate membrane merely. The body is concave below, and the inferior surface is furnished with a great number of tentacula, of which the exterior ones are the longest, and furnished with small cilia, each terminated by a globule: they sometimes contain air, and the internal ones are the shortest, the most simple, and the most fleshy. In the centre of these tentacula is the mouth, in form of a small proboscis, which leads to a simple stomach, surrounded by a somewhat glandular substance.

Cuvier, from whom a great portion of the above description is taken, says, in the last edition of the 'Règne Animal,' that there is but one species (*Porpita giganteu*) of a beautiful blue colour, from the Mediterranean and other warmer seas. Lamarck, who established the genus for an animal which had been placed among the *Medusæ* by Linnæus, gives four species; but De Blainville and MM. Chamisso and Eisenhardt coincide with Cuvier in believing that they are all referrible to one, though the former admits that the fact is still somewhat doubtful. He observes that Bosc's species, *Holothuria appendiculata*, (*Porpita appendiculata*, Lam.) was evidently established on an impaired animal. Eschscholtz, under the name of *Porpita Mediterranea*, conjoins three of Lamarck's species, and describes three new ones, taking for his character the proportion of the cartilaginous disk, and especially that of the marginal cirrhi.

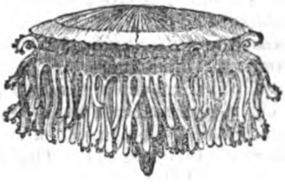
De Blainville, to whose article in the 'Dictionnaire des Sciences Naturelles' we refer the reader for further details, is of opinion that the genera *Velella* and *Porpita* might be united without inconvenience.

There is a very fair figure of a *Porpita* in an early volume of the 'Philosophical Transactions.'

Geographical distribution.—Like that of *Velella*, very wide. Bosc, who met with them at sea, says the animal has the appearance of a 24-sous piece borne along by the waves. Examples, *Porpita gigantea*, and *Por. glandifera.*



[Porpita gigantea.]
a, upper side; *b*, lower side.

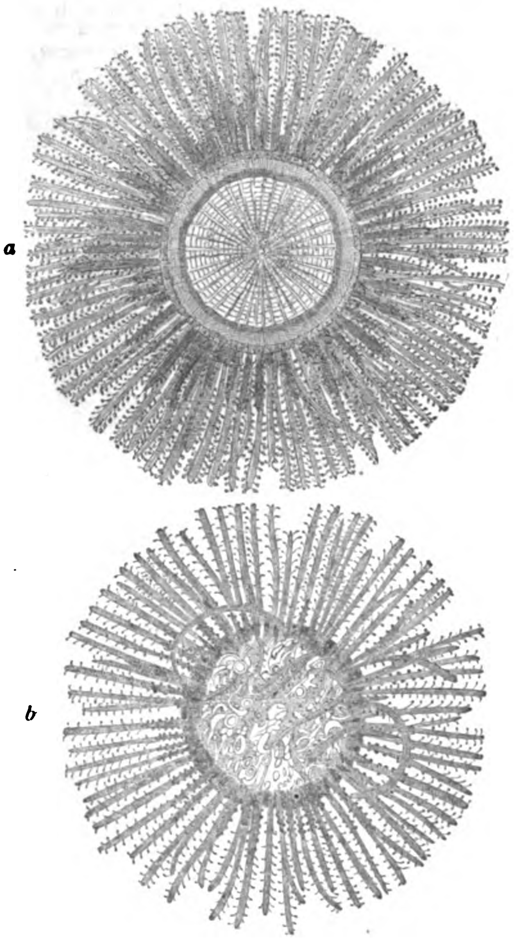


[Profile of Porpita glandifera.]

The Rev. Lansdown Guilding is of opinion that the genus *Porpita* should be restricted to those species which resemble *Porp. appendiculata*, which have few and broader arms, and establishes a new genus of the family *Porpitidæ* under the name of

POLYBRACHIONIA.

Dorsal support (sustentaculum) cartilaginous, naked, flattened, rounded, radiated, concentrically striated; *mantle* (pallium) narrow, free, surrounding the support; *arms*, numerous, parallel, of various lengths, elongated, affixed beneath, with a power of taking a declining position for the purpose of taking prey; *mouth*, below, central, purse-shaped, extensile; *tentacula* many, varying in form, suctorial, covering the whole ventral surface; *eggs*, very small, innumerable, nestled among the tentacula, (Guilding). Example, *Polybrachionia Linnæana*. Mr. Guilding describes the support as broad and vitreous, the body as cerulean, the tentacula as pallid, and the arms, which are in a triple series, glandulous, the glandules being pedunculated. The diameter of the mantle, exclusive of the arms, is stated to be eleven and a half lines. Mr. Guilding states that the animal is wonderfully beautiful, swimming, or rather floating on the serene surface of the Caribean Sea in calm weather, and embracing its prey by the sudden downward application of some or all of its arms, which are easily broken by attrition.



[Polybrachionia Linnæana, enlarged.[*]]

a, upper side ; *b*, lower side.

We think there is hardly enough to warrant a generic separation in this case ; the species bears a strong resemblance to the *Porpita cærulea* of Eschscholtz. Mr. Guilding observes that the *Medusa porpita* of the 'Amœnitates Academicæ' seems nothing more than the central disk of some species deprived of all the organs of the body.

CIRRHI'NUS, a genus of fishes. [Gobio.]

CIRRHI'PATHES. [Zoophytaria.]

CIRRHOBRANCHIA'TA. [Dentalium.]

CIRRHUS. (Conchology.) [Turbinidæ.]

CIRRI'PEDA, or CIRRHIPEDA.[†] *Lepas* of Linnæus, *Cirrhopodes* of Cuvier and Férussac, *Cirrhipèdes* of Lamarck, *Nematopodes* of De Blainville, *Cirripèdes* of Latreille: a well-defined natural group of marine invertebrate animals, whose place in the system has occasioned much doubt and difference of opinion among zoologists. In the earlier times the most absurd stories were propagated and believed in relation to one of the most common genera, *Pentalasmis anatifera, Lepas anatifera* of Linnæus, the common or duck barnacle. To the references on this head given under the article 'Bernicle,' we shall only add the testimony of Sir Robert Moray to show how long the delusion lasted, and in what positive terms a witness can state the thing that is not. 'In every shell that I opened I found a perfect sea-fowl; the little bill like that of a goose, the eyes marked, the head, neck, breast, wings, tail and feet formed, the feathers every where perfectly shaped, and blackish-coloured, and the feet like those of other water-fowl, to my best remembrance.' The Roman Catholics are permitted, in France at least, to eat the bernicle goose upon fast days and during the whole of Lent, in consequence of its supposed marine origin.

Organization, and place in the natural system.—Linnæus placed the *Cirripedia*, with the generic name of *Lepas*, among the *Multivalves* of his *Vermes* (*testacea*), between *Chiton* and *Pholas;* and, supposing that the form existed without a shell, found a situation for it under the name of *Triton*, between *Terebella* and *Lernæa*. Cuvier, in the first and also in the last edition of the 'Règne Animal,' says that the existence of these Tritons is not confirmed, and that we must suppose that Linnæus had only seen the animal of an *Anatifa* (Pentalasmis) which had been taken out of its shell. Rang, however, thinks that he has found the Linnæan genus *Triton* in certain specimens brought home by MM. Lesson and Garnot, Quoy and Gaimard, and has published it under the name of *Alepas*. Bruguières divided the genus *Lepas* into two; the first, *Anatifa*, a barbarous word for *Anatifera*, the Anatifes of the French, comprising the pedunculated cirripeds; and the second, *Balanus*, the sessile species. Cuvier, under the name of *Cirrhopoda*, made these animals the sixth class of his *Mollusks*, which he places between the *Brachiopoda* and the first class (Annélides) of his third great division of the animal kingdom, viz., the articulated animals, and in the 'Règne Animal' they appear between *Orbicula* and *Serpula*. Lamarck, under the name of *Cirrhipeda*, his tenth class of invertebrate animals, arranges them between the sedentary *Annelides* and his *Conchifera*, dividing them into two orders: 1st. The sessile cirripeds; 2nd. The pedunculated cirripeds. In his system they stand between *Magilus* and *Aspergillum*. Latreille, though he does not disturb this arrangement, evidently considers them as related to the *Ostracoda*, among the Branchiopodous crustaceans. He says that the sessile cirripeds seem to represent the animals which terminate the *Acéphales enfermés* of Cuvier. He observes that the two tubular processes of *Otion* represent the two tubes of some of the *Acephala*, though with different uses, the tentacula being converted into jaws. The *cirri* he considers as a kind of feet analogous to the sub-abdominal appendages of many crustaceans, especially those of the *Amphipoda*, and is of opinion that we may also compare them to those of many annelids. The oviduct, he remarks, has some resemblance to that of *Phalangium*. Finally he expresses a conjecture that nature, to form the *Cirripeds*, has borrowed different organs from animals of several classes. Mr. William Sharp MacLeay, in his profound and philosophical work, 'Horæ Entomologicæ,' considers that *Pentalasmis* exhibits the greatest affinity with the *Ostracoda;* but he seems to be of opinion that there exists an affinity between the shell of *Balanus* and that of *Echinus*, and sanctions Latreille's opinion that the articulated *cirri* have their analogues in the arms of the *Radiata*, particularly of *Comatula*. Dr. Leach, who has described several genera unnoticed till his time, divided the class into two orders: 1st. *Campylosomata*, comprising the pedunculated section; and 2nd. *Acamptosomata*, including the sessile species. M. de Blainville makes the cirripeds the first class (*Nematopoda*) of his subtype *Malentozoaria*, a group which corresponds to the Multivalves of Linnæus, after separating from them the genus *Pholas*, so that De Blainville's *Malentozoaria* consist of the *Cirripeds* and *Chitons*. The Cirripeds, he thinks, have an evident relation to the Bivalve Mollusks, by means of their calcareous envelope, in which he recognises the pieces of the shell of the *Pholades*, and even the analogue of the tube of the neighbouring genera. He also considers the relationship further indicated by the recurved position of the animal fixed head downwards (*la tête en bas*): but he also considers that their relations to certain animals of the type *Entomozoaria* are numerous, by means of the horny, locomotive, articulated appendages which are branchial, at least at the root, becoming, towards the mouth, true horny, denticulated jaws. Mr. Thompson, in his 'Zoological Researches,' considers the Cirripeds to be true *Crustacea*, and that in the first state of these animals they not only possess perfec dom and power of motion, but organs of sight. On the 28th April, 1823, Mr. Thompson states that he took in a small muslin towing net, while crossing the ferry at Passage, among other minute creatures, a small translucent animal, one-tenth of an inch long, of a somewhat elliptical form, but very slightly compressed laterally, and of a brownish tint. When in a state of perfect repose it resembled a very minute muscle, and lay upon one of its sides at the bottom of the vessel of sea-water in which it was placed; at this time all the members of the animal were withdrawn within the shell, which appeared to be composed of two valves, united by a hinge along the upper part of the back, and capable of opening from one end to the other along the front, to give occasional exit to the limbs. These were of two descriptions, viz.: anteriorly a large and very strong pair, provided with a cup-like sucker and hooks, serving solely to attach the animal to rocks, stones, &c., and, posteriorly, six pairs of natatory members, so articulated as to act in concert and to give a very forcible stroke to the water, causing the animal, when swimming, to advance by a succession of bounds after the same manner as the water-flea (*Daphnia*) and other *Monoculi*, but particularly *Cyclops*, whose swimming feet are extremely analogous. [BRANCHIOPODA.] The tail, usually bent up under the belly, is extremely short, composed of two joints, and terminating in four *setæ*, and is employed to assist in progression and in changing the position from a state of repose. The greatest peculiarity however in the structure is in the eyes, which, although constantly shielded by the valves of the shell, are pedunculated as in the crab and lobster, and placed entirely at the sides of the body. Mr. Thompson observes that this animal, but for its pair of pedunculated eyes, would find a place as a new genus of *Ostracoda;* that its members approximate it to *Argulus* on the one hand and to *Cyclops* on the other, genera which are widely separated; while the eyes show its relationship to the *Decapoda* (crabs, lobsters, &c.) The individuals presented no variation indicative of a difference of sex; and this, with their anomalous organization, induced a belief that they were the larvæ or disguised states of some crustaceous animal, or (as it had been previously ascertained that the *Cirripeds* were *Crustacea*) that they were the males of these, Mr. Thompson not being disposed to believe that the two sexes were united in the same individual. What follows being of the last importance, we give in the author's own words: 'Under the foregoing impressions, some of them were collected in the spring of 1826, and, in order to see what changes they might undergo, were kept in a glass vessel, covered by such a depth of sea-water that they could be examined at any time by means of a common magnifying glass; they were taken May 1st, and on the night of the 8th the author had the satisfaction to find that two of them had thrown off their exuvia (exuviæ) and, wonderful to say, were firmly adhering to the bottom of the vessel and changed to young barnacles, such as are usually seen intermixed with grown specimens on rocks and stones at this season of the year. (*Balanus pusillus*, Penn.) In this stage the sutures between the valves of the shell and of the operculum were visible, and the movements of the arms of the animal within, although these last were not yet completely developed; the eyes also were still perceptible, although the principal part of the colouring matter appeared to have been thrown off with the exuvium (exuviæ). On the 10th another individual was seen *in the act of throwing off its shell*, and attaching itself as the others to the bottom of the glass. It only remains to add, that as the secretion of the calcareous matter goes on in the compartments destined for the valves of the shelly covering, the eyes gradually disappear, from the increasing opacity thence produced, and the visual ray is extinguished for the remainder of the animal's life; the arms at the same time acquire their usual ciliated appearance. Thus then an animal originally natatory and locomotive, and provided with a distinct organ of sight, becomes permanently and immovably fixed, and its optic apparatus obliterated, and furnishes not only a new and important physiological fact, but is the only instance in nature of so extraordinary a metamorphosis.'

---

[*] From Mr. Guilding's figure, 'Zoological Journal,' vol. iii., p. 404, pl. X.

[†] The terms at the head of the article are those generally used by zoologists; but, correctly, the word should be *Cirripedia*, and Burmeister adopts that mode of writing.

'During the whole of the spring and summer months,' says Mr. Thompson, 'the water teems with these exuvia (exuviæ) of Tritones (the animal inhabitant, according to Linnæus, of the barnacles): it is impossible to avoid drawing up numbers every time a towing-net is thrown out, nay the tide is at times discoloured from their abundance; but to be certain that these are really such, let a stone with several barnacles upon it be kept in sea-water, regularly renewed, towards the latter end of April or the beginning of May, and with due attention many of them may be observed *in the act of throwing off exuvia* (exuviæ) in every respect identical; let it be recollected however that these are the casts of the *animal* alone, and not of the valves of the shell, or of the operculum.' Mr. G. B. Sowerby (*Genera of Shells*, 'Scalpellum') thus writes on the subject of Mr. Thompson's discovery:—'Without describing the facts, or entering upon the arguments with which he supports this opinion,' *i. e.* that the *Cirripedia* are *Crustacea*, 'we must be permitted to say that we do not think that he has fully demonstrated it; at the same time, considering that, as far as we hitherto knew, the Cirripedes were all attached, the circumstance of their being free when very young accounts well to our mind for the fact of each species being found attached to peculiar situations, which would only be compatible with the notion of their being at one time free agents, and possessed of an instinctive volition determining their choice of situation.' Mr. Owen, in the 'Catalogue of the Museum of the College of Surgeons' (Cirripeda), speaks of the discovery without expressing any doubt.

But Mr. Thompson has since, in a paper read before the Royal Society on the 5th of March, 1835, declared his 'discovery of the metamorphosis in the second type of the Cirripedes; viz., the *Lepades*, completing the natural history of these singular animals, and confirming their affinity with the *Crustacea*.' and the memoir with a plate is published in the second part of the 'Philosophical Transactions for 1835.' The following is the abstract of the paper:—'The discoveries made by the author of the remarkable metamorphoses which the animals composing the first family of the Cirripedes, or *Balani*, undergo in the progress of their development, and which he has published in the third number of his "Zoological Researches" (p. 76), are in the present paper, which is intended as a prize essay for one of the royal medals, followed up by the report of his discovery of similar changes exhibited by three species of two other genera of the second tribe of this family, namely, the *Lepades*. The larvæ of this tribe, like those of the *Balani*, have the external appearance of bivalve monoculi, furnished with locomotive organs, in the form of three pairs of members; the most anterior of which are simple, and the other bifid. The back of the animal is covered by an ample shield, terminating anteriorly in two extended horns, and posteriorly in a single elongated spinous process. Thus they possess considerable powers of locomotion, which, with the assistance of an organ of vision, enable them to seek their future permanent place of residence. The author is led from his researches to the conclusion that the Cirripedes do not constitute, as modern naturalists have considered them, a distinct class of animals, but that they occupy a place intermediate between the *Crustacea decapoda*—with which the *Balani* have a marked affinity—and the *Crustacea entomostraca*, to which the *Lepades* are allied; and that they have no natural affinity with the testaceous mollusca, as was supposed by Linnæus, and all the older systematic writers on zoology."*

Mr. Thompson does not seem to have been aware of a paper by Dr. J. Martin-Saint-Ange, read at the Academy of Sciences on the 14th July, 1834, and published in the 'Savans Etrangers,' tome vi., and separately by Baillière (1835). The following is the summary of the principal facts stated by him in the course of a very laborious and acute investigation. The mouth of the Pedunculated Cirripeds is composed of pieces entirely comparable to those of the mouth of many *Crustacea*, and especially of the *Phyllostomes;* the upper lip, the palpi, and the mandibles, are so analogous, that the resemblance extends even to the form. The three jaw-feet (*pieds-mâchoires*), which are met with most commonly in the Crustacea, are conjoined in a single jaw-foot which receives the nervous trunks; at its base are always found from two to four branchiæ. The ten ordinary feet of the Crustacea are faithfully represented in the *Anatifes* (Campylosomata); at the base of many among them are found branchiæ disposed like those of certain Crustacea, and the number even is sometimes repeated. There exists in each foot a double canal, fit for establishing a circulating current, and traversing all the articulations of the cirri. The body is composed of a certain number of rings, or of articulations, very distinct, each of which supports a pair of feet. In the interior of the body there are a dorsal vessel (like that in a great number of the articulated animals), and a double series of ganglions; of which the number, according to Dr. Martin-Saint-Ange's researches, is equal to that of the feet: there is besides another pair on the lateral parts of the stomach. The pedicle may be regarded as analogous to the tail of many Crustacea; it is in this cavity, and not, as has been said, on the back, that the eggs are found; these pass afterwards by a conduit, not yet indicated, in the envelope, which, by its resemblance to the mantle of the mollusca, establishes the only possible analogy between the Cirripeds and the last-named animals. The organs placed upon the back, which Cuvier described as eggs, are the generative apparatus of the male, of which the disposition is very remarkable. Finally, the stomach and intestinal canal enclose in the interior a membranous sac of a retort-shape; the disposition and use of which establish, according to the researches of M. Serres, an additional approximation between the Cirripeds and the Annelids. Dr. Martin-Saint-Ange then proposes as the last result of his labours, to place the class *Cirrhipeda* at the end of the *Crustacea*, so as to establish a natural link or passage between the superior articulated animals and the *Annelids*. Such are the conclusions drawn in the Memoir of Dr. Martin-Saint-Ange, who refers with approbation to the discoveries of Mr. Thompson, published in 1830; and before we proceed to the comments made on the Memoir of Dr. Martin-Saint-Ange, we will state Mr. Thompson's view of the ovarial system. 'In the whole of the tribe of the Cirripedes,' observes Mr. Thompson, in his paper in the 'Philosophical Transactions' above quoted, 'the ova, after expulsion from the ovarium, appear to be conveyed by the ovipositor into the cellular texture of the pedicle, just beneath the body of the animal, which they fill to the distance of about an inch. When first placed in this situation, they seem to be amorphous and inseparable from the pulpy substance in which they are imbedded; but as they approach to maturity they become of an oval shape, pointed at both ends, and are easily detached. Sir Everard Home has given a very good representation of them, at this stage of their progress, in his 'Lectures on Comparative Anatomy,' from the elegant pencil of Mr. Bauer. During the stay of the ova in the pedicle, they render this part more opaque and of a bluish tint; the ova themselves, and the cellular texture with which they are surrounded, being of a pale or azure blue colour. It is difficult to conceive in what manner the ova are extricated from the situation above indicated; but it is certainly not by the means suggested by Sir Everard Home in the above-mentioned lecture, viz., by piercing outwards through the membranes of the pedicle, for the ova are subsequently found forming a pair of leaf-like expansions, placed between either side of the body of the animal and the lining membrane of the shells in *Lepas* (Pentalasmis), or of the leathery internal tunic in *Cineras*. These leaves have each a separate attachment at the sides of the animal to the septum, which divides the cavity occupied by the animal from that of the pedicle; they are at first comparatively small, have a rounded outline, and possess the same bluish colour which the ova had in the pedicle; but as the ova advance in progress these leaves extend in every dimension, and lap over each other on the back, passing through various lighter shades of colour into pale pink, and finally, when ready to hatch, become nearly white. These leaves appear to be composed of a layer of ova irregularly placed, and imbedded in a kind of parenchymatous texture, out of which they readily fall when about to hatch, on its substance being torn asunder; indeed it appears at length to become so tender as to fall entirely away, so that after the period of gestation is past no vestige of these leafy conceptacles is to be found. When the larvæ, barely visible to the naked eye, burst forth from the ova, their development goes on with such rapidity that they seem to grow sensibly while under observation. The larva of the *Lepades* then is a tailed *Monoculus*, with three pairs of members, the most anterior of which are simple, the others bifid, having its back covered with an ample shield, terminating anteriorly in two extended horns, and posteriorly in a single elongated spinous process.'

---

* M. Straus Durckheim claims the priority of referring the Cirripeds to the *Crustacea*, and would place them next to *Limnadia*.

We now come to the report of MM. Duméril and Serres (drawn up by the latter) upon the Memoir of Dr. Martin-Saint-Ange. After adverting to the labours and views of Poli, Delle Chiaje, Home, Thompson, and Burmeister, the report states that the ganglionary nervous chain, pronounced by Cuvier to be single, has been found by Dr. Martin-Saint-Ange to be completely double: an important fact, more especially when it is compared with the duality of the nervous axis, which one of the reporters pointed out in the larvæ of insects and of certain Annelids, Hérold in the embryo of the Arachnids, Rathke in that of the crawfish, and MM. Audouin and Milne Edwards in many adult *Crustacea*. Thus, observe the reporters, the symmetry of the nervous system becomes a general rule, common to vertebrated and invertebrated animals. The remainder of this report is so interesting, and the reporters are such competent authority, that we find it necessary, for the better illustration of this obscure and long-debated subject, to give a portion of it at least, as nearly as we can in the terms of the reporters:—'The author,' say they, 'has discovered besides in the Cirripedes a small nervous apparatus placed on the side of the head, which had its principal trunk in a tubercle which occupies this region. At first sight we thought that this tubercle might be the remains of the eye observed in the young state by Mr. Thompson, at the period when these animals are free, and that the nervous apparatus might be the remains of that of vision; but a dissection in water and under the microscope has not justified this opinion. Our researches however were made upon subjects which had been a long time in spirit; and it would be important to renew them on fresh individuals of various ages, in order to prove whether the loss of the eyes is complete and absolute, or whether, as Mr. Milne Edwards has observed in *Cymothöe*, the organs are hid in the thickness of the head, where they terminate by withering away and disappearing. After the nervous system, one of the most controverted questions about the organization of the Cirripedes is that relative to their genital apparatus, and the mode in which their generation is carried on. We do not stop at the idea of Home, who makes the Anatifes germinate from their pedicle, nearly like buds from a stem. This hypothesis, which is opposed by the disposition of the parts, is besides destroyed by the fact recently discovered by Mr. Thompson; viz., that of the primitive freedom of the Cirripedes. If at first these animals are free, if they move in all directions by the aid of their feet, which serve them as oars, it is clear that an hypothesis which supposes them to be adherent and fixed at all periods is unworthy of a serious refutation. It is not so with the opinion of Cuvier, which deserves to fix our attention; inasmuch as, if it were well founded, it would constitute a new species of hermaphroditism. On each side of the intestinal canal of the Anatifes is found a substance composed of an infinity of granules; these granules united in a bunch (*en grappe*) enter a hollow pedicle; this pedicle in its turn opens into a larger canal plaited in zigzag, which united to its congener is prolonged into the proboscidiform tube. According to Cuvier, these granules and their bunches are the eggs and ovaries, the pedicles deferent canals, and the zigzag canal a sort of *vesicula seminalis*. On this hypothesis, the eggs detach themselves from the bunch and travel the length of the deferent canals and *vesicula seminalis*, becoming fecundated in their passage; they are finally deposited in the cavity of the mantle by the proboscidiform tube which terminates this apparatus: whence it results, according to Cuvier, that the same organic apparatus produces and fecundates the eggs, a condition which would amount to the most simple development of animal generation. But according to M. Martin-Saint-Ange, the whole of this apparatus only constitutes the male organ; the female organ being found enclosed (*renfermé*) in the cavity of the pedicle by which the Anatifes fix themselves to the bodies that support them. This is a renovation of the opinion of Poli and Lamarck, which Cuvier disregarded, because the pedicle appeared to him to be completely closed on the side of the animal. To give to this opinion the positive character which belongs to anatomy, the author ought to have found a passage which would place the interior of the pedicle in communication with the cavity of the mantle where the eggs group themselves, in the form of a rounded plateau. This communication was in fact made known to him by the discovery of a small conduit, which runs from the root of the pedicle along the bottom of the single piece (*pièce impaire*) of the shell, and opens in the interior of the mantle opposite the point where the eggs are assembled. The existence of this oviduct was placed out of doubt in three manners: first, the eggs being of a beautiful azure blue in the living animal, the author found them in the ovarial conduit, passing from the pedicle into the mantle; secondly, on blowing into the pedicle the mantle was raised like a bladder; thirdly, instead of air he injected a coloured size or varnish (*vernis*), and thus made the oviduct stand out, nearly in the same manner as vessels which would, from their minuteness and delicacy, escape the observer without such preparation.' The reporters then enter into a detail of their own experiments, and confirm this opinion of M. Martin-Saint-Ange, as combining in its favour every degree of anatomical certainty. They acknowledge that it may be objected that the ovary, in this case, is isolated from the fecundating apparatus; but observe that in this point the Cirripeds are in the same condition as the *Lophyropoda*, whose eggs are confined in a separate pouch placed at the superior border of the shell. Besides, direct observation proves that the eggs, which are in the state of ovula in the pedicle, present in the mantle the first lineaments of the embryo; a fact which agrees with the modern researches into the ovology of the *vertebrata*. The determination of the ovary and the discovery of the oviduct, then, in the Cirripeds are new facts; which, in extricating these animals from the state of exception in which Cuvier had placed them, subject them to the common law of generation. On the other side they return into a condition of exception by a fact of another description, little resemblance to which is at present known in comparative anatomy; viz., the possession of a second intestine enclosed within the ordinary one.

This second canal, discovered by the author and named by him a cæcum, floats in the alimentary canal and almost equals it in length. It is closed at its lower extremity, while at its upper extremity, which is open and wide, it is dovetailed (enchâssé par des dentelures) into the areolar lacunæ of the anterior of the stomach. In this cæcum the aliments are deposited to undergo the necessary elaboration preparatory to nutrition, so that, according to the opinion of the reporters, this last cannot be performed except by endosmosis, or by a species of rumination which would empty the contents of the second canal into the first. The reporters observe that they know only one animal, the common earth-worm, among the Annelids which has a second intestine enclosed in the alimentary tube; and there is still a difference; for, in that Annelid, the supernumerary intestine is closed at both extremities: it is in fact a double cæcum, which has induced M. Charles Morren (who, after Willis, Home, and Carus, has occupied himself specially with its study) to name it *typhlosole*. The reporters, after some other observations, address themselves to the subject of the approximation which M. Martin-Saint-Ange establishes between the Cirripeds and the Annelids. Agreeing with the majority of zootomists, the author allows that, in the greater part of their characters, the Cirripeds belong to the class *Crustacea*. Discussing then the value of the differential characters, he thinks, with M. Duméril and M. de Blainville, that they ought to serve as a passage from one class to the other. But while M. de Blainville considers the Cirripeds as *Crustaceous mollusks*, the author regards them on the contrary as *Annelidian crustacea*, and founds this decision on the duality of the nervous system, on the rudimentary segmentation of the body, and on the presence of nervous ganglions at the centre of the lineary divisions. The reporters remark that the same dispositions of the nervous system exist partially in *Cymothöe* and in the *wood-louse* (oniscus), and entirely in *Phyllostoma* and *Talitrus*, without a thought on the part of MM. Andouin and Milne Edwards, who made them known, to approximate those Crustacea to the Annelids. The reporters then observe, that although it is very true, as M. Martin-Saint-Ange observes, that in the greatest number of Mollusks the nervous system is united in one or more masses whence the nerves radiate, there are others in which the central nervous system is double, *Hyalœa*, *Aplysia*, *Bulla aperta*, *Tritonia*, *Doris*, *Clio Borealis*, &c., for example, which shows, as remarked by M. Serres, that the nervous system of the *Invertebrata* cannot alone furnish a solid basis for the methodical distribution of those animals. Laying aside the nervous system, the secondary characters of the Cirripeds most in accordance with the bases of natural classification are the shell and the mantle: here they would incontestably approach the Mollusks, if these parts were analogous to those which envelop the latter. But according to Professor Burmeister they are entirely different, and bear more resemblance to the external covering of the *Crustacea* than to that of the *Mollusca*. Hence, observe the reporters, it results that the place which the Cirripeds ought to occupy is still undetermined:—they conclude with a eulogy on the multitude of new facts so clearly presented and perfectly illustrated by M. Martin-Saint-Ange in his memoir.

That the paper of Dr. Martin-Saint-Ange is deserving of much praise, and that his illustrations, some of which are here copied, are very good, there is no doubt: but we must be pardoned for saying a word or two as to some of the facts alleged to be new. In the first place we must not forget Professor Burmeister,* whose admirable labours on the subject no one can follow without advantage; and in the next, we do not quite understand the statement in the report that the ganglionary nervous chain pronounced by Cuvier to be single has been found by Dr. Martin-Saint-Ange to be completely double, and we beg to refer to the following passage in Cuvier's 'Mémoire sur les Animaux des Anatifes et des Balanes.' 'The nervous system of the Anatife is entirely similar to that of the articulated animals.' Cuvier then speaks of the brain, composed of four small lobes, placed upon the œsophagus, and giving off four principal nerves which proceed to the muscles and the viscera. 'The *two lateral cords*,' he continues, 'which form, as usual, a collar round the œsophagus, each give off a nerve; they then unite below by means of two ganglions, whence proceed the nerves of the first pair of feet: the *two cords then proceed* in parallel lines (parallèlement), the length of the belly, between the bases of the feet, swelling from space to space into double ganglions, as in all the articulated animals, and giving off from each of these ganglions the nerves of the neighbouring parts.' And he gives a figure illustrative of the nervous system, and, among other portions,

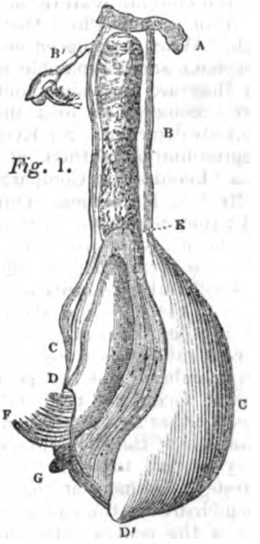


Fig. 1.

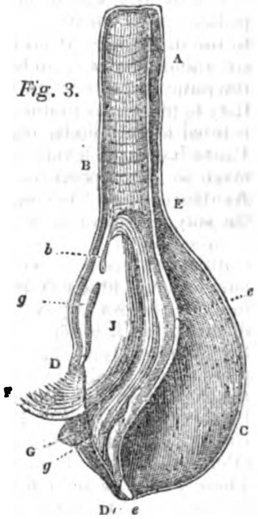

Fig. 3.

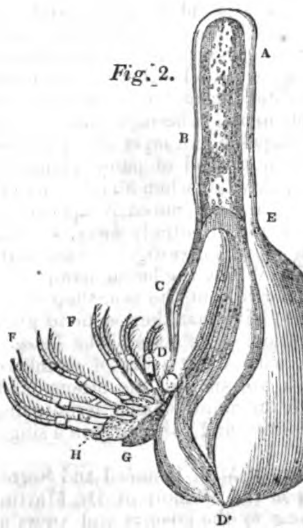

Fig. 2.

---

* Beiträge, 'Zur Naturgeschichte der Rankenfüsser,' Berlin, 1834.

of the Réunion des *deux cordons* lateraux, et premier ganglion. With regard to the internal cæcum floating in the alimentary canal, it should be borne in mind that the cuticular lining of the gizzard of the annelids is very easily separated. Among the annulose animals we know that when the common crab moults or changes its skin, it likewise casts the inner coat of the stomach.

1. Anatife jaune sans coquille, (Alopas?) A, a gelatinous production or continuation of the horny envelope which serves to fix the pedicle. B, the first membrane of the pedicle. B, a small anatife of the natural size developed upon the pedicle of the parent. C, the convex and swollen part which contains the body of the animal. D, the fissure of the horny envelope from which issue the feet or cirri, F. The point E indicates the termination of the pedicle and the place where the eggs stop. G, the eggs arrived within the mantle. 2. The same letters refer to the same parts as in figure 1. H, the part of the feet which sustains the cirri F. At the base of the feet (H) are four branchiæ; and between these feet and those placed on the other side is seen the recurved tube which serves to convey the seminal liquor within the mantle. 3. The same anatife, from which the half of the first envelope has been taken so as to expose the interior. The pedicle contains a second cylinder terminated in a cul de sac by its inferior extremity, and covered at the other by a very delicate membrane; the longitudinal and transverse muscular fibres may be observed. *e e* indicate the canal which carries the eggs of the pedicle within the mantle; *b*, that which serves as a nourishing vessel to the pedicle and the eggs; *g, g*, the membrane of the mantle which intercepts all direct communication between the pedicle and the cavity of the mantle. J represents the body of the anatife enclosed in its proper envelope. 4. The same situation as the last, representing all the membranes which envelop the body of the anatife. B B, the muscular cylindrical pipe open, in which the eggs are seen. *e, e*, the course of the oviduct in the thickness of the second envelope. *g, g, g*, the envelope opened and turned back. J, J, J, the proper membrane of the body of the animal; it is with this cavity that the canal *b* communicates, and it is between this proper membrane and that of the second envelope *g, g, g*, that the eggs are found: whence it results that the cavity of the mantle has no communication with the pedicle, except by means of the oviduct *e*.

19. A side view of the common duck barnacle (*Pentalasmis anatifera*) taken out of the shell, enveloped in its proper membrane, under which is found the salivary vesicle. V, the cervical ganglion. *v'*, the nerve which is given off from the brain to go to the muscles of the skin. J, the two levator muscles of the upper lip. K K, branchiæ. *h*, a horny tubercle which is formed on each side of the orifice of the vent. U', the extremity of the tube, bearded with fine hairs. 18. Anterior view of the same, showing the truly articulated disposition of the body, each ring of which corresponds to a pair of feet. S, the adductor muscle of the valves. U', the articulated tube which contains the spermatic canal. 1. The intestinal canal of the same species. (N. B. It is identical with that of the naked species above described.) D, the mouth seen from the side; *d*, the œsophagus; *d'*, the stomach; *d''*, the pedicle which makes this organ communicate with a species of cæcum, *d'''*, of the same structure and form as the stomach. T, the intestinal canal, offering two natural curvatures. *h*, orifice of the rectum. U U, vesiculæ seminales, uniting in a single canal very delicate, and terminated at U' by a small orifice. 8. Disposition of the nervous system. 1. The first œsophagian ganglion, called the brain: from these united ganglions spring the branches *v*, *v'*, *v''*, destined for all the muscles of the dorsal part, and two extremely delicate threads which go on each side, the first to the salivary vesicle V, the second to a new ganglion Z. 2. The second ganglion, sending two nervous branches to each jaw-foot F, and small branches to the œsophagus. 3, 4, 5, 6 correspond to the other ganglions. 6 furnishes the two last pair of feet. It is from the branches which go to the last feet, and not from the ganglions themselves, that the two threads *y* and *g'*, which go to the extremity, U', of the tube are detached. The point *x* corresponds to the centre of the œsophagus which has been removed.*

For the fruits of Hunter's anatomical investigations in this class, the student is referred to the following numbers in the gallery of the Museum of the Royal College of Surgeons:—63, 64, 65, 582, 1011, 1012, 1013, 1014, 2298, 2299, 2300, 2302, 2303, 2810. Let him consult also Poli, ('Testacea utriusque Siciliæ;') Cuvier, ('Mémoires sur les Mollusques;') Sir E. Home, ('Lectures on Comparative Anatomy;') and Dr. Hermann Burmeister's valuable work above quoted.

Geographical Distribution.—The Cirripeds are widely spread, and scarcely any seas are without some of the species. Their habit of fixing themselves so frequently to floating bodies tends to their great diffusion, and, in addition to this propensity, almost every rock and submarine body is studded with some of them.

ARRANGEMENT.

Cirripedia.

Animal marine, more or less conical; sometimes compressed; enveloped in a sacciform mantle, open only on one side, swollen as it were at the anterior part, which, following the natural position of the animal, is the lower portion, terminated above by a certain number of pairs of long, horny, articulated, ciliated cirri, and curved at the summit. No distinct head, no eyes, and no true tentacula; the mouth furnished with lateral, horny, toothed and articulated jaws. Branchiæ situated on each side at the base of the first cirri; orifice of generation at the extremity of a fleshy tube raising itself from the midst of the last cirri; vent at the base of this tube.

Shell variable, but when present always composed of many valves, either soldered or not soldered together: no true shell in one case only, and in that instance a soft envelope in lieu of it; the shell or its representative adhering without intervention, or by the intervention of a fleshy peduncle which issues from the mantle.

Order 1.

Campylosomata.

Anatifa of Bruguières; Cirripèdes pédonculés of Lamarck; Anatifes of Férussac; Gymnodermes and Ostracodermes of Latreille; Lepadiens of De Blainville.

Animal oval, compressed; suspended in its shelly envelope, to which it adheres by a transverse muscle situated near the opening. Mantle open solely on one side, and inferiorly attaching itself to the edge of the shell, and prolonged on the other side into a contractile and fleshy pedicle, adhering by its extremity to submarine bodies; branchiæ pyramidal, adhering on the outside of the base of the cirri.

---

* The figures and descriptions are taken from Dr. Martin Saint-Ange's Memoir.

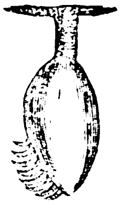
Shell.—Almost always composed of five principal pieces or valves, rarely without any vestige of these testaceous portions, but in that case replaced by a subcartilaginous and thick envelope; principal valves triangular, delicate, touching or overlapping each other at the edges; sometimes rudimentary, and in that case very much separated. The valves are thus disposed: two large lateral valves receiving the transverse muscle; beyond these two smaller lateral valves, and a mesial valve serving to join all together. There are often a number of accessory pieces fixed at the base.

Habits.—The genera of this order affix themselves by means of their pedicle to submarine bodies, forming numerous groups. They are often found on floating substances far at sea: on ships, on logs of timber, on bottles, on net-corks, on fuci, on floating testaceous mollusks, *Ianthina* for instance, and even on some of the vertebrated animals, on whales, turtles, and even serpents—*Hydrophis*, for example. Other testaceous mollusks might be mentioned, and one species has been found parasitical within the umbrella of a *Medusa*. A large log of timber covered with these animals, twisting and diverging in all directions, and so thick as entirely to hide the surface of the log, is a strange sight. They look like an enormous collection of serpents to the ignorant; and we have heard a living mass of this description casually thrown into shallow water and left by the tide, so termed. Their growth must be extremely rapid. A ship going out with a perfectly clean bottom will often return from a short voyage covered with them below the water line. The Blacks of Goree are said to eat a large species of *Pentalasmis*, which is stated to be delicate.

Genera, Alepas.

Animal oval, compressed, bean-shaped, rounded near the pedicle, which is moderately long. Cirri rather short, and hardly recurved at their summit.

Shell replaced by an entire subgelatinous and somewhat transparent envelope, without any other opening than that which serves for a passage to the cirri, continuing itself with the pedicle, and presenting no trace of testaceous pieces. Such is the description of Mr. Rang, who has given the generic appellation above stated to the *Cineras parasita* of Lesson, and the *Anatifa univalvis* of Quoy and Gaimard. The species on which the genus was founded was detected attached to the umbrella of a *medusa*. Rang considers this to be the *Triton* of Linnæus. Cuvier, in the last edition of the 'Règne Animal,' observes that he has not seen the species, but still adheres to his old opinion; for he says that it ought not, in any case, to be confounded with the *Triton* of Linnæus, which was the animal of an *Anatifa* torn from its mantle and shell. Rang thinks that this and the following genus connect the last family of the *Acephala* with the first of the *Cirripedia*.



[Alepas parasita.]*

Gymnolepas.

Otion and *Cineras*, Leach; *Aurifère*, De Blainville.

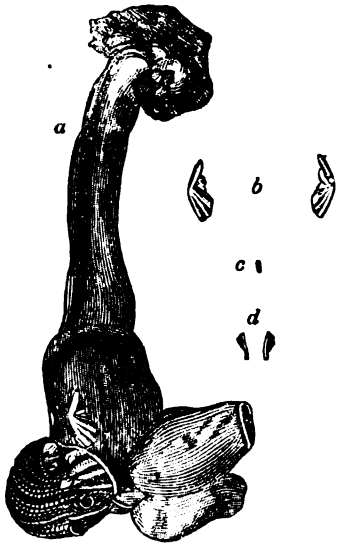
Animal compressed, with the cirri much recurved at their extremity. Mantle nearly entirely naked, thick and subcartilaginous. Pedicle long and thick.

Shell rudimentary, composed of small valves very much separated. Locality, probably warm climates. *Otion Cuvieri* has been received from Senegal; and there is a fine group on *Coronula diadema*, a parasite of the South Sea Whale, in the Museum of the College of Surgeons, Nat. Hist., No. 281.

a.

Two auriform tubes at the summit. (Genus, *Otion*, Leach; *Aurifère*, De Blainville.)

Example. *Gymnolepas Cuvieri*, *Otion Cuvieri*, *Lepas aurita*, Linn

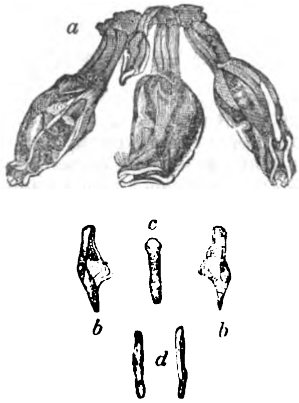


[Gymnolepas Cuvieri.]

a, Gymnolepas Cuvieri; *b*, the lateral valves; *c*, the single valve; *d*, the terminal valves.

β.

No auriform tubes · form more angular. (*Cineras*, Leach.)



[Gymnolepas vittata.]

a, Gymnolepas vittata; *b*, the lateral valves; *c*, the single valve; *d*, the terminal valves.

The small valves in *Otion* were overlooked by Lamarck, but detected by Leach. In the Museum of the Royal College of Surgeons, Nat. Hist., No. 265, there is a species named *Cineras Hunteri*, of which two small groups are attached to the tail of *Hydrophis bicolor*, which is figured in Russell's 'Indian Serpents,' 1, tab. xli., and is called by the natives 'Nalla Wahlagillee Pam.' Russell says, 'This sea-snake, according to the Vizagapatam fishermen, seldom approaches the shore: several of them had never seen one before. They pretended it was of a very dangerous kind, which is contradicted by the want of poisonous organs.' See 'Catalogue of the Museum,' part iv., fasciculus 1; and 'Shaw's Lectures.' which are there quoted also.

Pentalasmis.

Anatifa, Bruguières and Lamarck; *Pentalepas*, De Blainville.

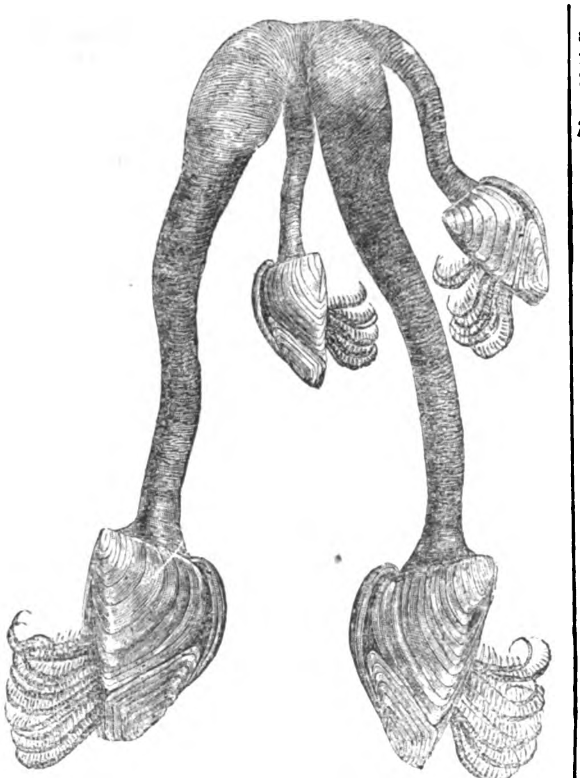
Animal compressed, enveloped in a very delicate mantle. Pedicle often very much elongated. Cirri curled at the summit. Locality, widely spread in most seas. Plentiful on the coast of Africa.

Shell subtriangular, formed of five distinct pieces completely enveloping the animal.

Example. *Pentalasmis anatifera*, *Anatifa lævis*, Lam.; *Lepus anatifera*, Linn. Duck-barnacle.

---

* From M. Rang's figure



[Pentalasmis anatifera.]

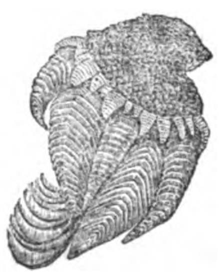
Pollicipes.

Pentalepas of De Blainville.

Animal like that of *Pentalasmis*, but with a shorter pedicle, which is rough, somewhat like shagreen.

Shell triangular, composed, besides the principal side valves, of a number of accessory pieces fixed at their base. Locality, temperate and warm seas.

Example. *Pollicipes mitella*, Lamarck; *Anatifa mitella*, Bruguières; *Lepas mitella*, Linnæus.

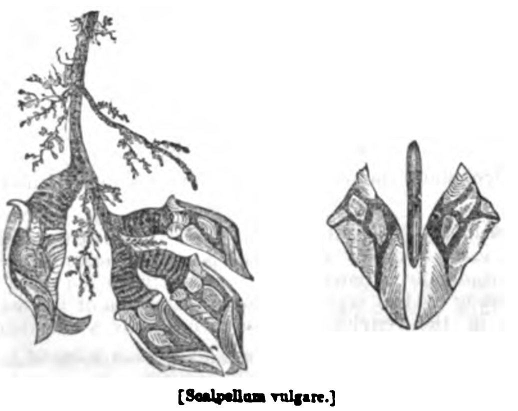


[Pollicipes mitella.]

Scalpellum.

Polylepas of De Blainville.

Animal resembling that of *Pentalasmis*. Pedicle shorter and scaly.



[Scalpellum vulgare.]

Shell formed of thirteen pieces, completely covering the animal. Locality. Of the two species known, one is common in the European seas, and the other was found in the Straits of Magalhaens.

Example. *Scalpellum vulgare*, Leach; *Pollicipes scalpellum*, Lamarck; *Anatifa scalpellum*, Bruguières; and *Lepas scalpellum*, Linnæus.

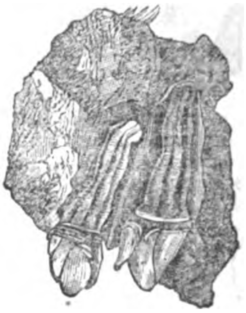
Lithotrya.

Litholepas, De Blainville.

Animal compressed.

Shell irregularly subpyramidal, compressed, supported on a tubular, tendinous pedicle. Valves eight. At the base of the pedicle a shelly appendage, analogous to the testaceous base of *Acasta* and *Balanus*. Mr. G. B. Sowerby, who instituted the genus, considers it as intermediate between the sessile and pedunculated cirripeds; and states that it possesses a peculiarity not to be found in any hitherto described genus of this class, viz., that of penetrating stones for its habitation. Rang says, that De Blainville is of opinion that the genus is only a true *Anatifa* which had affixed itself upon the valve of a *Venerupis* at the bottom of one of the cavities which that bivalve hollows out for itself. De Blainville, in his 'Malacologie,' describes it under the name of Litholepas, sinking Sowerby's name altogether, though he says the genus was newly established by him, quotes his description, and merely states that he has never seen the cirriped. Whether it bores holes for itself or occupies those already hollowed out is doubtful.

Example. *Lithotrya dorsalis*, Sowerby. Locality, Montserrat, one of the Antilles.



[Lithotrya dorsalis.]

N.B. Cuvier gives a genus, *Tetralasmis*, which he describes as having but four valves surrounding the opening, two of which are longest. He says that the animal is in part contained in the pedicle, which is large and covered with hair. He considers these as a sort of Balani without a tube, and gives as an example *Tetralasmis hirsutus*. Cuv. 'Moll. Anatif.,' f. 14.

Order 2.

Acamptosomata.

Les Balanides of De Blainville; Cirripèdes sessiles of Lamarck; Balanes of Férussac; Quadrifères and Bifères of Latreille.

Animal conical, sometimes very much depressed, and sometimes nearly cylindrical; for the rest, similar to that of the preceding family, but without a pedicle, and having the branchiæ in form of two fringed wings attached to the internal surface of the mantle.

Shell thick, solid, variable in form, but nevertheless always conical or sub-cylindrical, adhering by its base to the surface of foreign bodies or penetrating within them, composed of a cone formed of one or more pieces united laterally, open at its base, or closed by a membranous or calcareous piece, serving for adhesion; always open at the summit, but furnished at this part with a pyramidal operculum, consisting of two or four valves.

This order was well known to the antients. The genera seem to have been all confounded under the name of Βάλανος (Balanus) by the Greeks. (Aristotle, 'Hist. Anim.' book iv., ch. 8, and book v., ch. 15.) Athenæus mentions them more than once; and (Deipnos, book iii., ch. 11, p. 88) speaks of the large ones with approbation as an article of food. They are the *Balani* of the Latins: nor did Lucullus disdain them. The Chinese eat the soft parts of one of the species (*Balanus tintinnabulum*), which has the reputation of being like the flesh of the lobster when cooked; and the delicious qualities of another species, and its high estimation for the table, will be found under the article **Balanus**.

M. Rang, whose arrangement we for the most part adopt, observes that many genera have been formed, some of which it may be necessary to disallow. The longitudinal tubular cavities with which the cone is pierced, and which open at the base, where they are said to be very sensible, are a distinguishing character of the order.

a. Cone univalve.

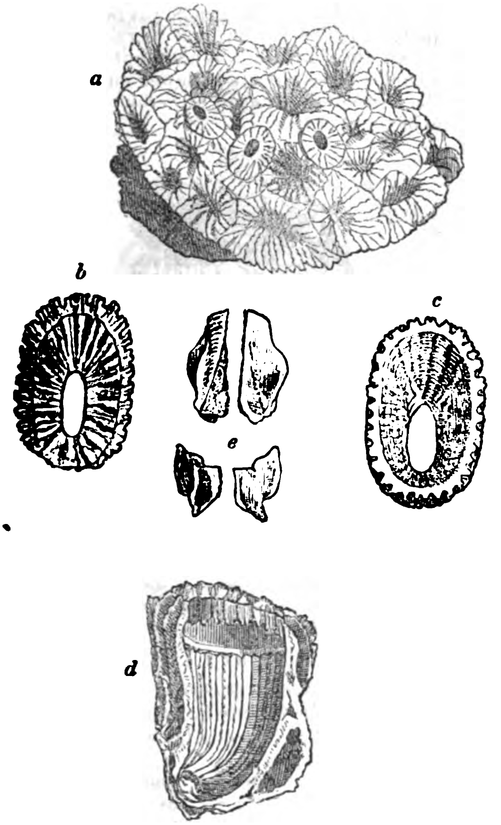
Genera, Pyrgoma. (Boscia of Férussac.)

Shell thick, generally compressed and somewhat conical, but sometimes regularly conical, open at the apex, and closed at the base by a deeply cup-shaped testaceous valve, striated or grooved perpendicularly in the inside; the operculum bipartite, each part composed of two valves, which are variable in form, the posterior one being in some species very much elongated (Sowerby).

Savigny appears to have instituted the genus, and Leach and Lamarck have adopted it: the former subsequently subdivided it into *Pyrgoma*, *Megatrema*, *Savignium* and *Adna*.

Habits. Either adherent on or penetrating into corals: in some cases entirely overgrown by them.

Example. *Pyrgoma crenatum*.



a, specimens of the natural size in Astræa favosa; *b*, *c*, *d*, different views and section of the cone; *e*, the opercular valves*; *b*, *c*, *d* and *e*, are magnified.

β. Cone quadrivalve.

* Operculum bivalve.

Clitia, Leach. (Verruca, Schum.? Ochthosia, Ranzani?)

Shell consisting of four irregular pieces, two larger and two smaller, dovetailed together by their dentated edges. Operculum bivalve, one piece irregularly quadrate, the other nearly triangular.

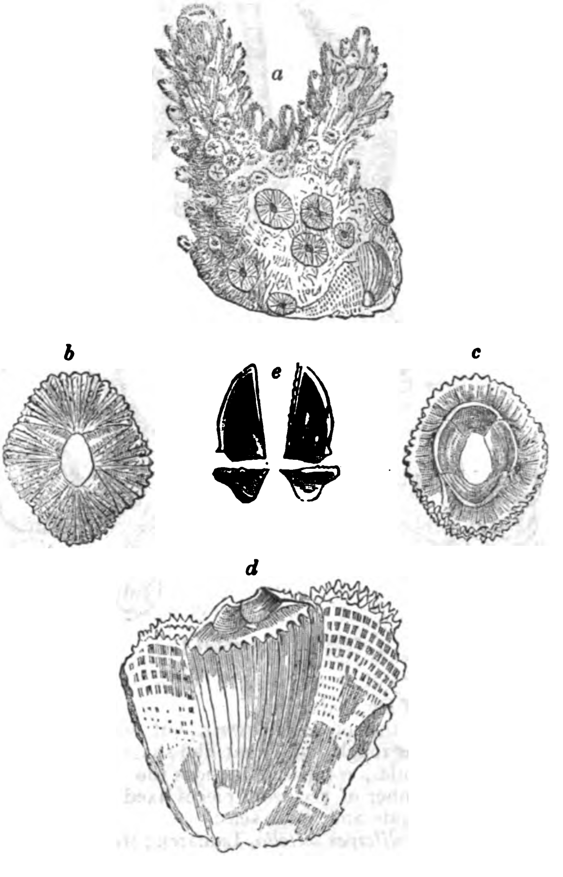
Example. *Clitia verruca*, *Lepas striata* of Pennant; *Lepas verruca* of Gmelin. Locality, British coasts

[Clitia verruca, enlarged.]

Creusia, Leach.

Shell somewhat flat, slightly conical, composed of four unequal valves; base deeply cup-shaped. Example, *Creusia gregarea*, Sowerby.

Habits. Like *Pyrgoma*, affixed to, or buried in, madrepores and other corals.



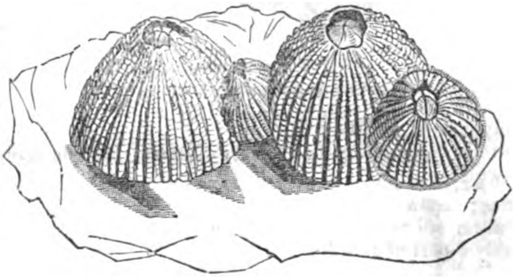
[Creusia gregarea.]

a, natural size in a madrepore; *b*, *c*, *d*, cone and section magnified; *e*, opercular valves magnified.

Conia, Leach.

(Azemus, or Asemus, Ranzani; Polytrema, Férussac.)

Shell subconical, composed of four subtriangular subequal valves; longitudinal tubes highly developed. Example, *Conia porosa*. Locality, Mediterranean, West Indian, and other seas.



[Conia porosa.]

γ. Cone with six valves.

* Operculum composed of separate pieces, not articulated.

Tubicinella.

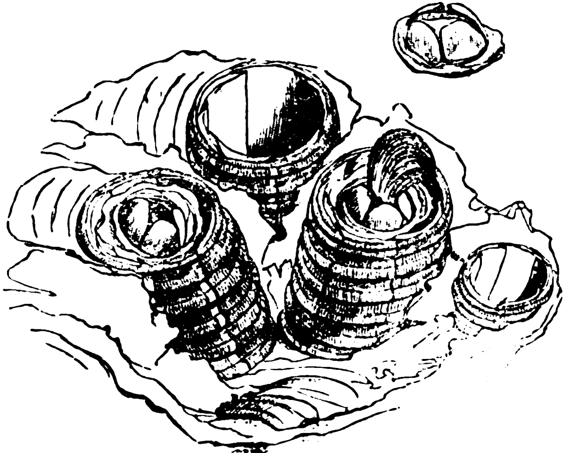
Shell subcylindrical; the cylinder, which is truncated at both ends, formed of six ligulate pieces, smooth within, but longitudinally striated and transversely ringed without, affording no bad representation of a portion of the windpipe in the vertebrata, closed beneath by a membrane.

---

* The cuts of Pyrgoma, Clitia, Crensia, Catophragmus, and Octomeris, together with those of some of the detached valves of the Campylosomata, are taken from Mr. G. B. Sowerby's 'Genera of Recent and Fossil Shells,' where the reader will find much valuable information illustrated by engravings of great accuracy.

Example, *Tubicinella balænarum*, Lamarck. The only species known.

Habits. Buried nearly up to the summit of the aperture in the skin and fat of whales, which are sometimes infested with it to an enormous extent.

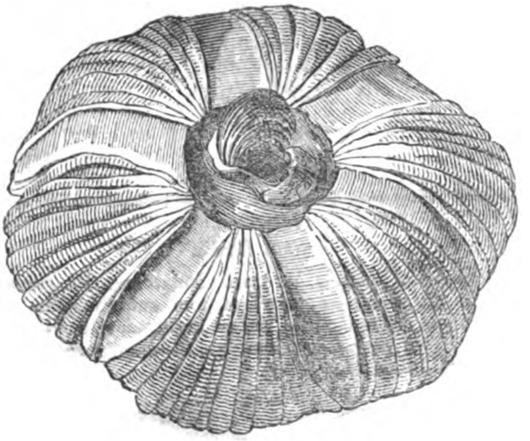


[Tubicinella balænarum.]

Coronula.

(Chelonobia, Leach; Cetopirus, Ranzani; Diadema, Schumacher.)

Shell suborbicular, subcylindrical, but generally obtusely, not to say flatly conical, constituted of six unequal ribbed pieces, so completely soldered as to bear the appearance of one; the lower side instead of longitudinal tubes presenting radiated cells in those species which infest the *Cetacea*. Example, *Coronula balænaris*. Locality, South Seas, imbedded in the skin and fat of whales. *Coronula testudinaria* (*Chelonobia* of Leach, &c.) adheres to the backs of turtles (*Cheloniæ*).



[Coronula balænaris.]*

* * Operculum quadrivalve, articulated.

Chthamalus.

A genus instituted by Ranzani; described as having a very depressed shell, with six pieces or valves, very thick at their base, and forming very regular rays; support membranous; aperture tetragonal, with almost equal sides; operculum subpyramidal. Locality, Mediterranean: most probably a part of Leach's Coniæ.

[Chthamalus stellatus.]

Balanus.

(See the article, vol. iii., p. 310.)

Acasta.

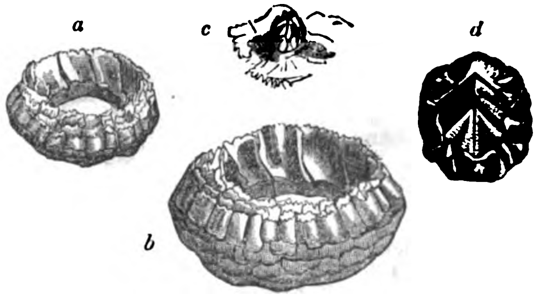
(See Balanus.)

δ Cone with eight valve

* Operculum bivalve.

Catophragmus, Sowerby

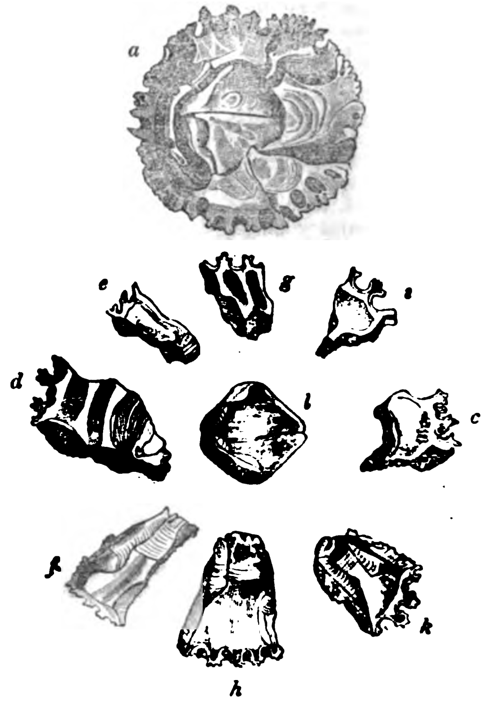
Shell subconical, composed of eight unequal valves. There is a curious peculiarity about the genus. 'This,' says Mr. G. B. Sowerby, 'consists in a number of narrow perpendicular valves arranged around the shelly cone, and in rows, like pales, the first row of which consists of eight pieces, placed so as exactly to cover the sutures of the shelly cone immediately surrounding the animal; around this are then placed several sets of more and more numerous pieces gradually decreasing in size, so that the outer row, which is the most numerous, consists also of the smallest pieces. Additional rows seem to be produced as the animal increases in age; for a young specimen in our possession has only one row of eight pieces covering the sutures of the first cone, while a much larger and older specimen still retains part of three rows, and has evidently lost some of the external rows. The young individual also shows that the whole of the pieces are pointed at their superior extremities, whereas in the old shell these extremities are so worn or eroded as to become very irregular and obtuse.' Example, *Catophragmus imbricatus*, Sowerby. Locality, West Indies.



[Catophragmus imbricatus.]

a, the old shell, natural size; *b*, the same magnified; *c*, the young shell, natural size; *d*, the same magnified.

Octomeris, Sowerby



[Octomeris angulosa.]

a, the outside; below, an internal view of the eight divisions; *c*, the anterior piece; *d*, the posterior piece; *e* to *k*, the lateral pieces; *l*, the operculum, consisting of four pieces, of which the two anterior are the larger.

---

* The cirri are here represented as exserted; but they are capable of being withdrawn into the hood or collar formed by the opercular valves and intervening membrane for their protection. A most elaborate and beautiful illustration of the anatomy of the animal (Coronula Diadema) is given by Dr. Burmeister in the work above quoted, p. 34, pl. 2. There is a noble specimen (Coronula diadema), with a group of Gymnolepas Cuvieri attached to it, in the Museum of the College of Surgeons (Nat. Hist., in spirit, No. 981), and alluded to under 'Gymnolepas.'

The genus rests on the following characters. Cone of eight pieces; internal sutures of the pieces or valves angular; shelly parts foliaceous; no internal plate; a thin epidermis. Example, *Octomeris angulosa*, Sowerby.

The student should examine the fine collection of Cirripeds in the British Museum, and he will find some good examples of the soft parts both of the Campylosomata and Acamptosomata in the Museum of the College of Surgeons, in the Natural History department (subjects preserved in spirit), numbers 258 to 282, both inclusive.

FOSSIL CIRRIPEDIA.

Pentalasmis. Mr. G. B. Sowerby says that fossil specimens of this genus are exceedingly uncommon; and adds, that he has never seen anything but fragments from two beds; viz., the Calcaire grossier of Grignon, and the Suffolk crag. [BALANUS.]

CIS, a genus of Coleopterous insects of the family Ptinidæ (Leach). They are minute beetles which infest the various species of Boleti. They are of an oblong, nearly cylindrical form, and generally of a brown colour: their tarsi are four-jointed, and the antennæ have the basal joint large, and the three apical joints forming a club. Fourteen species have been discovered in this country, the largest of which is scarcely one-eighth of an inch in length.

CISALPINE REPUBLIC. [BONAPARTE, p. 122.]

CISNEROS*, **FRANCIS XIMENEZ DE**, a celebrated statesman and patron of literature, a cardinal and primate of Spain, was born in 1437 at Torrelaguna in New Castile. He studied at a school at Alcala de Henares and at the university of Salamanca, and afterwards went to Rome, where he acquired such reputation, that Sixtus IV. promised him the first vacant prebend in the cathedral of Toledo; but the Archbishop of Toledo, vexed at this inroad on his patronage, and at the firmness with which Cisneros demanded it as his right, threw him into a dungeon. Being released at the end of six years, Cisneros went to Siguenza, where Cardinal Mendoza appointed him his grand vicar. In 1482, abandoning his brilliant prospects, he embraced the Franciscan rule. In 1492 Queen Isabella took him for her confessor, and in 1495 nominated him Archbishop of Toledo. This honour he declined with a firmness which nothing but the commands of the pope could overcome. In this exalted station he retained all his monastic severity. He constantly wore under the pontifical robes the coarse frock of St. Francis. In his travels he always endeavoured to lodge at some convent of his order, and he conformed to all the rules like an ordinary member. He set apart half of his enormous revenue (at that time amounting to 200,000 ducats) for the relief of the necessitous; and he made a daily distribution of provisions to thirty poor. He also expended considerable sums in the ransom of captives.

In 1498 Cisneros founded the University of Alcala de Henares, in which he provided for poor students, appointed a fund for prizes, and invited distinguished men from Paris, Bologna, Salamanca, and Valladolid. He instituted also a seminary for young ladies of respectable families who were destitute of fortune. Adjoining it he established a nunnery for those among them who chose to retire from the world: to the rest he allotted portions, and disposed of them in marriage suitably to their condition.

In 1502 he undertook, assisted by eminent scholars, his Complutensian Polyglot, the type and the model of all subsequent ones. He sent to every quarter for MSS., and Leo X. obliged him with a communication of what he possessed. He collected seven copies in Hebrew at the expense of 4000 ducats, besides procuring from Rome a Greek MS., and from other quarters many Latin MSS.: not a single manuscript of this collection was of less antiquity than 800 years. The whole charge of the undertaking, which was completed in fifteen years, amounted to the immense sum of 50,000 ducats.

On the death of Queen Isabella in 1504, as all parties strove to attach Cisneros to their interest, he became the arbitrator between King Ferdinand and the Archduke Philip, the husband of Joanna, heiress of the crown. On the death of Philip, two years after, Cisneros was appointed regent on account of the incapacity of Joanna and the absence of Ferdinand. This was a critical moment for him, but his prudence overcame all difficulties, and kept all parties in check. He levied troops at the public expense, totally independent of the grandees, from whose hands he succeeded at last in rescuing the crown. He thus began, perhaps unconsciously, to vindicate the rights of the people against the nobility in Europe. By the feudal system, the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field as their vassals. A king with scanty revenues therefore depended on them in all his operations. In 1507 Julius II. gave him the cardinal's hat. In 1508 the septuagenarian cardinal set off from Malaga at the head of 10,000 foot and 4000 horse for the conquest of Oran, a splendid city on the coast of Africa, which he added to the Spanish dominions at his own expense.

When Leo X., in order to raise money to complete the church of St. Peter, proposed to sell dispensations, Cisneros opposed the introduction of the pope's bulls into his diocese. On another occasion, as a primate of Spain, he prevailed on the king to exclude all bulls but what had received the sanction of the royal council; and ever since that time this salutary advice has been acted upon in Spain. At another time he opposed a claim of the same pope to the tenth of ecclesiastical benefices, and obliged him to be content with a tax of a tenth upon the clergy of the States of the Church.

Ferdinand at his death, 23rd January, 1516, left Cardinal Cisneros regent till the arrival of his grandson, Charles I. of Spain, afterwards Charles V. of Germany. The Dean of Louvain (afterwards Pope Adrian VI.) opposed this nomination. Cisneros however consented to admit him into the administration, and chose Madrid for his residence, that he might be more independent of the nobility, and better able to control their factions. He viewed with contempt the libels which were published against him, and always refused to inquire after the authors. The grandees objected to the power of Ferdinand to confer the regency, himself being only a regent, as the widower of Isabella; and the letter of Charles, which Cisneros showed them in ratification of Ferdinand's will, they treated as a mere matter of form. To satisfy their objections at once, the cardinal coolly requested them to wait upon him. From a balcony he showed them 2000 men in array, with a formidable train of artillery, which he ordered to be discharged. 'There,' said he, raising his voice, 'are the powers which I have received from his Majesty, and in a word *hæc est ultima ratio regum*.'

John Albret, the dispossessed king of Navarre, supported by some of the grandees, was forming a scheme to recover his kingdom. Cisneros, who had foreseen the danger long before, ordered a powerful body of troops to enter Navarre, and completely frustrated the attempt. To secure Navarre, he caused its numerous and expensive fortresses to be demolished, except Pampeluna, which he strengthened. To this precaution Spain is indebted for the preservation of Navarre. The French since that time have often overrun the open country, but not finding the former places of retreat and defence, they have been obliged to abandon it. In order to pay the debts of Ferdinand and the officers of his new militia, and to establish numerous and well-furnished magazines, Cisneros boldly undertook the abolition of unnecessary pensions, and enforced the restitution of many extensive crown demesnes, which had been alienated chiefly to the nobility in the late reign. He did not spare his dearest friends, nor even men of learning. The historian Peter Martyr of Anghierra and Gonzalez Oviedo suffered with the rest, and in revenge have defamed the cardinal's character.

While Charles remained in Flanders, every pretender to favour resorted thither, but nothing could be obtained without pecuniary application to his favourite Chièvres. Great sums were drawn out of Spain, and everything was disposed of to the highest bidder. The inferior officers followed the example of their head, and this infamous traffic became general. On the other hand, seeing Flanders on the eve of becoming a distant province of a vast monarchy, the Flemish ministers detained the king as long as they could, spreading all the time delusive reports of his instant departure, and cheating the cardinal under the pretext of defraying the expense of the king's voyage. When after twenty months of entreaties Cisneros prevailed on Charles to embark for Spain, and was himself proceeding towards the coast to meet him, he was seized with a violent disorder, at the convent of Bozeguillas, near Aranda de Duero, which was attributed to poison. The Spanish grandees and Flemish courtiers now regulated the advance of the court by the probable extent of the cardinal's life. Weakened by disease, fatigue, and austerities, he still directed, to the great vexation of the courtiers, the helm of state, and seemed to survive only to evince his greatness of soul unimpaired by bodily suffering. Under pretext of giving time to the towns for preparing the honours due to the king, they succeeded in deferring his entry into Castile till the cardinal's death, which happened on the 8th of November, 1517, but not before Charles, whose pride was worked upon by his flatterers, had written, to his eternal shame, a letter to the great Cisneros signifying to him his dismissal. Thus was a virtuous man, upon the verge of finishing his mortal career, after having governed Spain for twenty years, and accomplished all that could be done for her greatness and tranquillity, and for the increase too of the royal prerogative—thus was an illustrious statesman rewarded by a prince who was indebted to him for the very foundation of his future power. Among the great men who have admired Cisneros, the name of Leibnitz should be mentioned. The rare union of calmness, firmness and decision in Cisneros, is well shown in Gometius (Gomez de Castro), 'De Rebus gestis à Francisco Ximenio;' in Marsollier, Flechier, Moreri, and Robertson.

---

* He derived this surname from his family having been long established at Cisneros, in the province of Leon. The Spaniards generally call him Cardinal Cisneros; but in biographical and other works he goes under the name of Ximenez. He must not be confounded with Roderic Ximenez, a previous archbishop of Toledo, who is the author of 'Rerum in Hispania gestarum Chronicon;' and of 'Hispania Arabum.'

CISS'AMPELOS PAREIRA, the Pareira-brava, a native of several of the West Indian Islands, of New Spain, and of Brazil. The root of this plant arrives in Europe in pieces from two to three feet long, varying in thickness from that of a finger to an arm, curved, furrowed, and warty, with a thin closely-adhering bark of a greyish-brown colour. The woody part is tough, but so porous that air can be blown from one end to the other of a long piece; the concentric circles are very conspicuous; the axis is not in the centre. The odour is very faint, but the taste is at first sweetish or liquorice-like, afterwards nauseous and bitter. Analysed by Feneuille it was found to consist of—

Soft resin; a yellow bitter principle (tonic); a brown principle; animalized matter, starch, malate of lime, nitrate of potash, and other salts.

The juice of the fresh plant in its native country is said to be a very efficacious application to the bites of serpents; but in Europe the root is employed only as a tonic diuretic. It is particularly valuable in cases where there is a copious discharge of urine with a ropy alkaline mucus. (Brodie's *Lectures on Diseases of the Urinary Organs.*) It is also serviceable in catarrhus vesicæ, and other affections of the urino-genital organs.

There is great reason to believe that the roots of several different species of this or closely-allied genera are confounded under the name of Pareira-brava, especially the root of Cissampelos Caapeba, also of C. Mauritanica (Aubl.), C. parroides (Decand.), which is much esteemed in the East Indies given along with aromatics in diseases of the intestines. Two species of Aleuta, A. rufescens (Aub.) and A. candicans (Decand.), are used in Guyana.

The Pareira-brava contains so much mucilage that it coagulates water in which it is put to infuse. A syrup of this plant is a valuable demulcent in phthisis pulmonalis, or consumption.

CISSOID (*κισσο-ειδης*, resembling ivy), a name given to a curve first considered by Diocles (an Alexandrian, and posterior to Pappus, as is supposed from the latter not mentioning the name of Diocles among those who invented methods for inserting two mean proportionals (*Math. Coll.*, book iii. prop. 5), which rises towards an asymptote, and then obtained its fanciful name. It was one of the curves employed by the Greeks in the celebrated problem of finding two mean proportionals, and is described as follows:—Let two points (A) and (B) move with equal velocities round a circle, setting out from the ends of a diameter in opposite directions of rotation. Let a straight line (P) always pass through the starting point of (A), and through (B) as it moves; and let an ordinate (Q) perpendicular to the line joining the two starting points always pass through (A) as it moves. Then the intersection of (P) and (Q) traces out the cissoid, which has the line joining the starting points for its tangent at the commencement, and the tangent to the circle passing through the starting point of (B) for its asymptote.

But the term cissoid has been applied in later times to all curves described in a similar manner, and where the generating curve is not a circle. The cissoid of the Greeks should then be called either the cissoid of Diocles or the circular cissoid. The starting point of (A) being the origin, the line joining the starting points the axis of x, and a the radius of the circle, the equation of the cissoid of Diocles is—

$$y^2 = x^3 \div (2a - x)$$

CISSOPIS. [Bethylus.]

CISTA'CEÆ, a natural order of Polypetalous exogens, belonging to the Calycose group; among which they are known by their opposite or alternate undivided leaves, generally strongly impregnated with a fragrant resinous secretion, regular flowers having crumpled petals and indefinite stamens, and fruit with parietal placentæ; a simple style, and a large number of seeds containing in the midst of albumen an embryo with the radicle remote from the hilum. They are remarkable for the beauty of their fugitive flowers in the genera Cistus and Helianthemum. The species of the genus Cistus are all natives of the southern countries of Europe, where the summers are hot and dry, however severe the winters may be. They flourish upon rocky places, which they perfume with their fragrant leaves. Cistus creticus and some other purple-flowered species produce the substance called Gum Labdanum.

[Cistus creticus.]

CISTE'LIDES, a family of Coleopterous insects of the section Heteromera and subsection Stenelytra. Technical characters:—Claws of the tarsi pectinated beneath; antennæ with the basal joint free, *i. e.*, not covered by a projecting portion of the head; mandibles with the apex entire.

This family includes the genera *Lystronichus*, *Cistela*, *Mycetocharus*, *Allecula*, and some others.

Lystronichus.—Of this genus there are upwards of thirty species known; their colouring is for the most part brilliant and metallic; by far the greater portion of them are found in South America. They have the thorax depressed and with the posterior part as wide as the elytra, or nearly so; the antennæ are filiform, sometimes growing slightly thicker towards the apex.

Cistela.—The characters of this genus are:—Head long and somewhat pointed in front; labrum in width and length nearly equal; antennæ rather long, sometimes serrated, or with most of the joints triangular; body elongate-ovate; thorax broader behind than before.

Nearly forty species of this genus are known, most of which inhabit Europe, and four or five are found in this country.

Cistela Ceramboides is nearly half an inch in length; black with ochre-coloured elytra, and, like most of the insects of this section, is found in flowers.

Cistela sulphurea (Allecula sulphurea of some authors) is about one-third of an inch in length, and its colour is pale-yellow throughout. This species is more common in this country than the last, and appears to be confined chiefly to the sea coast, where, like the one above mentioned, it is found in flowers.

Mycetocharus.—In this genus the head is short and rounded, and the labrum is transverse; the antennæ are shorter, and the body is more elongate than in Cistela. About ten species are known, most of which inhabit Europe and North America; but one is found in England (Mycetocharus scapularis); this is about three-sixteenths of an inch in length; black; the elytra with two orange-coloured spots at the base; the base of the antennæ and the tibiæ and tarsi are yellow.

The larva of this insect, together with those of one or two other species of the Cistelides, are figured in the first volume of the Entomological Society's Transactions, where an account of their habits will also be found.

The genus *Allecula* (Latreille) may be distinguished from either of the foregoing genera by the species having the penultimate joint of the tarsi bilobed, and the terminal joint of the palpi securiform.

Upwards of thirty species of Allecula have been discovered, most of which inhabit South America.

CISTERCIANS. [BERNARDINES.]

CITADEL (remotely from the Latin *civitas*, and immediately from the Italian *cittadillo*), a fortified post within or adjoining a town. It serves either to keep the inhabitants in subjection, or as a place of retreat for the garrison when compelled to abandon the town to an enemy. A citadel should be constructed in a situation where it may be easily succoured; its fortifications should be stronger than those of the town, in order that the enemy may be induced to attack the latter first; and it should be separated from the buildings of the town by an esplanade.

CITEAUX, or, as it was formerly written, **CISTEAUX** (in Latin, **CISTERCIUM**), the site of a celebrated abbey in the department of Côte d'Or, in France: it is about four miles E. from the town of Nuys, which lies on the road from Dijon to Châlons sur Saône. This abbey owed its origin to Robert, Abbot of Molême, of the order of St. Benedict, who, wishing to lead a stricter life, obtained permission of the pope to break the vows which he had made as a Benedictine, and to take upon himself others of a severer character. Accompanied by twenty-one monks, he retired to the forest of Citeaux, in the diocese of Châlons, and having obtained a grant of land of Reynard, viscount of Beaune (or, according to some, of the bishop of Châlons), and cleared the ground, he laid the foundations of the abbey and church. The abbey is said to have been of wood. Robert was elected abbot of the new community, which had not at first any new rule, but strictly observed that of the Benedictines. After a time, Robert was directed by the pope to return to his charge at Molême, where the disorders which had probably caused his retirement had proceeded to a great length. The third abbot of Cîteaux was Etienne or Stephen Harding, an Englishman (canonized as St. Etienne), who may be regarded as the real founder of the Cistercian order (les Citeaux), as until his time no establishment had sprung from this monastery: in 1113-1115 were founded the first four establishments of which this can be regarded as the parent.

The monks of this order have been sometimes called Bernardines, from St. Bernard, one of the promoters of the order, and sometimes White Monks, from their habit, a white cassock with a white gown for attending the church, but a black one when they went abroad. The abbey of Citeaux was a very rich establishment previous to the Revolution; their revenue, according to Expilly, was about 110,000 livres or francs (above 4000*l.*), and the extent and imposing appearance of the buildings were indicative of its rank as the chief house of a monastic order. The community consisted usually of about 80 monks, beside 40 domestics. The church and a chapel under the portico contained the tombs of about 60 princes of the ducal house of Bourgogne, who made this their chief burial-place. Among those who have been inmates of this house, are St. Bernard and the four popes, Eugenius III., Gregory VIII., Celestine IV., and Benedict XII. The church and monastery have been destroyed, and there are now but few remains.

CITHARA, an antient stringed instrument of the lyre kind. That the names of the comparatively modern instruments, the gittern, or cittern, and guitar, are derived from the name of the Greek instrument (κιθάρα), we can have no doubt; and it is reasonable to infer, not only from similarity of appellation, but from the remains of antique art, that the modern instruments in many respects resemble that of the antients.

CITHAR'INUS, a genus of fishes of the salmon tribe (*Salmonidæ*), which inhabit the Nile. These fishes are chiefly distinguished from their allies by the depressed muzzle, the upper margin of the mouth being formed of the intermaxillary bones, the maxillaries being very small. The tongue and palate are smooth; the adipose fin is covered with small scales as well as the greater portion of the caudal fin.

CITOLE, a musical instrument mentioned in the *Confessio Amantis* of Gower, which was, Sir John Hawkins conjectures, a dulcimer.

CITRENE. The volatile oil of lemons consists almost entirely of a peculiar carburetted hydrogen, to which the name of citrene has been given.

CITRIC ACID. This acid is contained in several fruits, but in the largest quantity in limes and lemons. It was first procured in the state of crystals by Scheele. It may be obtained by the following process: to a gallon of lemon-juice made hot, add gradually 10oz. of chalk reduced to fine powder; set the mixture aside, that the precipitate, which consists of citric acid and lime, or citrate of lime, may subside. Wash this frequently with warm water, and then mix with it 10 ounces by weight of sulphuric acid previously diluted with 7 pints of water; boil the mixture for a quarter of an hour; press the residue strongly in a cloth, and evaporate the strained liquor with a gentle heat so that crystals may be formed. These crystals are to be rendered pure by repeated solution in water and recrystallization.

In this process the malic acid, gum, and extractive matter of the lemon juice, which prevent the acid from being obtained pure by mere evaporation, remain in solution, while the citrate of lime is precipitated, which being decomposed by the sulphuric acid, sulphate of lime is formed, and remains insoluble, while the citric acid, nearly pure, remains in solution and crystallizes by evaporation.

The properties of citric acid are, that it is colourless, inodorous, extremely sour; the primary form of the crystal is a right rhombic prism, subject to numerous variations. These crystals suffer no change by exposure to air under common circumstances; when heated to little below 212° they melt in their water of crystallization, and without losing any weight they concrete on cooling into a hard transparent mass. At a little greater heat they decompose. One hundred parts of the crystals are dissolved by 75 of cold and 50 of hot water: the solution reddens litmus strongly; decomposes by keeping; they are slightly soluble in alcohol.

Citric acid consists of

4 equivalents of oxygen . .	32	or	55·18
2 „ hydrogen .	2		3·44
4 „ carbon . .	24		41·38
Equivalent . .	58		100

The crystals, obtained as above mentioned by the cooling of a saturated solution, consist of

1 equivalent of dry acid . .	58
2 „ water . . .	9
	67

When the solution from which the above-described crystals have been obtained by cooling is subjected to spontaneous evaporation, the acid is procured in a different crystalline form, the crystals consisting of 3 equivalents of dry acid and 4 of water, half of which is expelled at a temperature of about 80° Fahrenheit.

When citric acid is decomposed by heat it yields a peculiar acid, called pyrocitric acid, a spirituous liquor analogous to pyroxylic spirit, and an oily matter, which by the long contact of water is converted into the two preceding substances, acetic acid, water, carbonic acid, carburetted hydrogen, and a coaly residue.

Citric acid is used as a discharge in calico printing, and as a substitute for lemon juice in making saline draughts, and in making effervescing lemonade with the sesquicarbonate of soda: tartaric acid, sometimes substituted for it on account of its cheapness, is less agreeable, and has the inconvenience of forming a purgative salt with the soda.

Citric acid combines with different bases to form citrates, but during its combination with them it is very apt to undergo change of composition.

Citrate of Ammonia is a very soluble salt, and does not crystallize till the solution is evaporated almost to the consistence of honey.

Citrate of Potash is a deliquescent salt.

Citrate of Soda crystallizes in prisms; it is slightly efflorescent, and soluble in three-fourths its weight of water: it fuses before decomposition.

Citrate of Lime, as already mentioned, is very slightly soluble in water, requiring about 500 times its weight; it is rendered more soluble by excess of acid. Citrate of magnesia is soluble, but the citrates of barytes and strontia are insoluble.

Of the metallic citrates, those of iron are soluble, that of zinc slightly so; those of copper, silver, and lead, are insoluble: no citrate whatever is applied to any use, except the solution of citrate of potash. extemporaneously prepared as antifebrile medicine.

CITRON. [CITRUS.]

CITRUS, a genus of Aurantiaceous plants, one of whose species yields the orange, another the lemon, and others the citron, shaddock, lime, and similar fruits. Among the other genera of the natural order to which it belongs, it is known by its stamens being numerous and irregularly combined into several parcels, and by its fruit having a leathery rind which can be easily separated from the pulpy part that lies beneath.

It is a common opinion that the golden apples of the Hesperides were the fruit of some species of this genus, but as the gardens of these fabulous personages were stationed, according to the most approved opinions, either among the mountains of Atlas or to the west of them, there is no probability that the opinion alluded to is correct; for independently of the historical facts that citrons and lemons at least were obtained from the Persians, it is certain from the researches of Wallich and other Indian botanists that it is among the lower ranges of hills in Nepal, and most probably in China also, that the wild states of the Citrus genus find a home. It is added that the sweet orange itself comes from the southern provinces of China and the Malayan Archipelago, but it is by no means clear that the plant in those countries is really wild; it is however beyond all question also of eastern origin.

Eight species are enumerated by Risso, whom we follow in the present article; we regard it however as a matter of great doubt how far they are really distinct. The orange, the lemon, the lime, and the citron were all that could be distinguished amongst the mass of specimens collected for the East India Company in Nepal; and there is no great difficulty in believing that all the numerous varieties now cultivated in every part of the temperate and tropical zones, both of the old and new world, have in reality sprung from those four original sources: part of them being natural varieties obtained by long cultivation, and part being hybrids created by accidental circumstances or artificial means.

1. *Citrus Aurantium*, the sweet orange. (*Oranger* of the French, *Arancio* of the Italians.) Stem arborescent. Leaves ovate-oblong, acute, a little serrulated, with the stalk more or less winged. Flowers white. Fruit many-celled, roundish, very seldom pointed, golden-yellow or tawny. Cysts in the rind convex. Pulp very sweet. The principal varieties of this are:—

a. The China orange, with ovate-oblong leaves; round, smooth, rather flattened fruit; and a thin golden-yellow rind. This is the common orange of the markets, and of the Portuguese.

b. The pear-shaped orange, with elliptical, acute leaves, and great top-shaped fruit, with a deep yellow smooth rind; a rare and curious sort not known in the market; it is one of the most capable of resisting cold.

c. The orange of Nice, with ovate-acute leaves, and large, thick-skinned, rough, dark yellow, round fruit. This is considered one of the finest of the whole genus, both in regard to beauty, size, productiveness, and quality. It is a good deal cultivated about the town whose name it bears.

d. The tiny-fruited orange, with ovate-oblong acute leaves, tiny globose fruit, and a thin, smooth, golden-yellow rind. Supposed to have been brought from the Philippines. The fruit is more curious than beautiful or good.

e. The fingered orange, with little stiff leaves, and ovate fruit, some one at least of whose lobes is separate from the remainder, and horned; rind pretty thick. This must not be confounded with the fingered citron hereafter to be mentioned.

f. The blood-red orange, with ovate-oblong pellucid leaves, and middle-sized, round, rough, reddish-yellow fruit; with a pulp irregularly mottled with crimson. This, which is said to have come from the Philippines, was once looked upon as a great curiosity, and living plants were purchased at a considerable price; it was thought to be produced by grafting an orange upon a pomegranate. Now that it is known to be a variety of indifferent quality, and that its fabulous history is forgotten, it has ceased to attract much notice. A trifling variety of it is the Arancio di Sugo rosso of the Italians, who call the real blood-red variety Arancio di Malta sanguigno. Another variety, with small fruit, is the Arancio a Foglia stretta of Nice.

g. The ribbed orange, with oblong acute leaves, and a flattened ribbed deep orange fruit. This is one of the most tender of the varieties; its fruit is spongy, and of no value.

h. The sweet-skinned orange, with broad taper-pointed leaves, roundish, rather ovate heavy fruit, and a deep yellow, smooth, thick, sweet, soft rind. This is the Pomme d'Adam or forbidden fruit of the shops of Paris. Its pulp is subacid and pleasant, and as deep a yellow as the rind, which is soft and melting like the flesh of a cling-stone peach; the acidity of the pulp is agreeably mixed with sweetness, and renders the fruit extremely pleasant. This is very different from the forbidden fruit of the London shops; see C. decumana farther on.

i. The Mandarin orange, with flattened, rough, deep orange fruit, and a thin rind, which separates spontaneously from the pulp. This sort has been raised in China, where its fruit is chiefly consumed in presents to the great officers of state, whence its name. It is now cultivated in Malta, where it arrives at perfection. Its singularity consists in the rind so completely separating from the pulp when quite ripe that the latter may be shaken about in the inside. In quality this yields to no known kind. There are two sub-varieties.

k. The Saint Michael's orange, with small, round, pale yellow, seedless fruit, having a thin rind and an extremely sweet pulp. This, when in a state of perfection, is perhaps the most delicious of all the oranges, and it is by far the most productive. Great quantities are imported from the Azores, where it appears to be exclusively cultivated as an object of trade. It is said that 20,000 of these oranges have been packed from a single tree, exclusively of the large quantity which were blown down or rejected as unfit for sale.

Besides these, there are numerous other sorts to be found in the gardens of the curious, and in commerce are many kinds about which little is known. Among these may be mentioned the egg-oranges of Malta, which are sometimes sent to England as presents; they are not however equal in quality to the China or the St. Michael's varieties.

2 *Citrus Bigaradia;* the Bigarade, or bitter orange (*Bigaradier* of the French, *Melangolo* of the Italians). Branches spiny. Leaves elliptical, acute, with a winged stalk. Flowers very white. Fruit middle-sized, uneven, more or less globose, deep yellow, with an acid and bitter pulp. It differs moreover from the sweet orange in forming a smaller tree, having broader leaves, and larger and sweeter flowers, on which account it is always selected in preference for the purposes of the perfumer. Its fruit is much more uneven. Numerous varieties of it are known, among which are all those cultivated for the sake of their flowers; especially the horned Bigarade, a variegated variety of it, and the curled-leaved Bigarade. The

following are a few of the most striking forms of this species :—

a. The horned Bigarade, with a large pale yellow ribbed fruit, whose sides project into horns. This variety, which is of the same nature as the fingered sweet orange (var *e.*), its horned appearance being caused by the separation of the carpels or fruit-lobes, is in great estimation on account of the powerful and delicious perfume of its flowers. It is the *Melangolo a frutto cornuto* of the Italians.

b. The Female Bigarade, with a deep yellow large coarse fruit, containing orange within orange. The circumstance from which this variety derives its name is not at all uncommon in the genus Citrus, but it exists here in perhaps the most strongly-marked manner. An orange, in its natural state, consists of one whorl of carpels, which are consolidated into a round fruit, each of whose lobes is one carpel. But it sometimes happens that two whorls of carpels combine to form the same fruit; in that case the inner whorl is consolidated into a central orange, and the outer whorl grows over it. Or, it may happen that three whorls of carpels constitute the fruit; in that case the innermost whorl will combine into an orange in the centre; the second whorl will form a coating over it; and the most exterior whorl will enclose the whole. Finally the carpels may separate wholly, as in the fingered citron, or in part, as in the fingered orange and Bigarade, and then the fruit consists of a number of lobes more or less distinct. Until the discovery made by Göthe of the real nature of compound fruit, oranges of this kind were looked upon as something wondrous, and many idle speculations existed as to their cause. A figure of this may be found in Risso's *Histoire Naturelle des Orangers*, t. 33, without however any explanation of the cause of the monstrosity.

c. The curled-leaved Bigarade; with very compact, blunt, small, curled leaves, and flowers growing in thick clusters at the ends of the branches. No variety is more generally cultivated than this for the sake of its flowers, which are large, sweet, and produced in extraordinary profusion. The French gardeners call it *Le Bouquetier*, or Nosegay plant, and *Bigaradier riche dépouille;* the Italians *Melangolo riccio*. The fruit is coarse, very light, uneven, and with a large conspicuous scar at the point. The plant itself is far more dwarf than the other varieties, and is one of the most robust of its race. It is a common object of cultivation all over the south of Europe.

d. The purple Bigarade; with leaves, flowers and fruit stained more or less with a dull purple, especially the young leaves. *Hermaphrodite* and *Bigarade violette* of the French, *Melangolo Pavonezzo* of the Italians.

e. The double-flowered Bigarade; with rather thick leaves, double flowers, round granulated fruit, and a thick rind; the common double orange of the nurseries. It is a great favourite in gardens, because of its multitudes of fragrant double flowers, which do not fall in pieces so quickly as those which are single; it loses its quality of producing double flowers if the soil in which it grows is not kept in a very rich state.

f. The Seville Bigarade or orange; with round dark fruit, having an uneven, rugged, extremely bitter rind. Commonly brought to the English market, where it is consumed in the manufacture of bitter tinctures and in the preparation of candied orange-peel. The bitter aromatic principle is a powerful tonic; it gives its flavour to the liqueur called Curaçoa.

g. The myrtle-leaved Bigarade; with small, very compact, ovate, sharp-pointed leaves, and small round fruit. Generally both in flower and fruit at the same time, if well cultivated. On this account and because of its dwarf habit, it is a very common object in gardens. It is said to be a Chinese production, and that it is employed by the Chinese gardeners as an edging of flower beds, in the same way as the dwarf box in this country.

h. The Bizarre Bigarade; with curled, rather deformed leaves, purplish or white flowers, and fruit of different sorts, some being round and of the common appearance, others half bigarades and half lemons or citrons, the pulp of some being sweet, that of others acid and bitter. A curious lusus naturæ, which was once thought to be the greatest prodigy in all the vegetable kingdom. It is however merely one of those sports, as they are technically called by gardeners, in which, owing to some unknown cause, some one individual assumes the appearance of two or more others in particular parts. Analogous instances are the grape called the variegated chasselas, some of whose fruit is black, some white, and some striped with both colours; the camellia, which bears red, white, and party-coloured flowers on the same stem; and the chrysanthemum, some of whose flowers are purple and others yellow. This Bigarade was raised from seed by a gardener at Florence in 1644, and has since been multiplied by grafting, and so has been preserved to the present day. It may be procured from the nurserymen of France and Italy, and it fruits annually in the orangery at Versailles.

3. *Citrus Bergamia*, the Bergamot Orange. Leaves oblong, flowers small, very sweet. Fruit pearshaped or flattened, rugged, with a greenish-yellow smooth rind filled with concave receptacles of oil. Pulp subacid, very fragrant. The trees of this species are rather variable in appearance. The fragrance of both flowers and fruit is peculiar. From each of them the perfumer procures an essence of a delicious quality. The rind, deprived of the pulp, first dried, and then moistened with water, is pressed in moulds into fancy boxes for holding lozenges and other sweetmeats, and these boxes retain much of their recent odour. The Mellarosa of the Italians is a variety with ribbed fruit, having a broad scar at the summit; it is much esteemed on account of the abundance of its flowers.

4. *Citrus Limetta*, the Lime. Leaves ovate, obovate, and oblong, placed upon a wingless stalk. Flowers small and white. Fruit ovate or roundish, pale yellow, with a boss at the point; the cysts in the rind concave; pulp subacid. In foliage this resembles the lemon, but its fruit differs in the pulp never having the sharp and powerful acid of the lemon; it is on the contrary flat and slightly bitter: it is principally employed for flavouring punch, sherbet, and similar drinks. The varieties are of no importance; they principally differ in the thickness of their rind and in form. Here is to be arranged the round very uneven fruit called Pomo d'Adamo by the Italians, because they fancy that the depressions upon its surface look as if they still bore the marks of our universal father's teeth.

5. *Citrus decumana*, the Shaddock. Leaves large, with a winged stalk. Flowers very large and white. Fruit usually very large, roundish, pale yellow, smooth, with flat or convex cysts in the rind. Rind white, spongy, very thick; pulp juicy, sweetish, rather insipid. Shaddocks are among the largest fruits which are known, and are commonly cultivated in both the East and West Indies for the sake of the delicate subacid juicy pulp in which they abound. When they arrive at their greatest size they are called Pompoleons, or Pompelmousses; when at the smallest they form the Forbidden Fruit of the English markets. Another small variety, with the shaddocks growing in clusters, forms a larger tree than any other citrus; the fruit is about as large as the fist; it is what the West Indians call the Grape-fruit.

6. *Citrus Lumia*, the sweet Lemon. Leaves like those of the lemon. Flowers red externally. Fruit with the flesh and rind of a lemon, but with the pulp sweet, and the cysts in the rind both convex and concave. There can be no doubt that this is a mere variety of the next species, from which it only differs in the want of acidity in the pulp. Many sorts are known in orange countries, of which one, the *Commander's Pear*, resembles very much a large Beurré Pear; their fruit is seldom seen in England.

7. *Citrus Limonum*, the true Lemon. (*Citronnier* of the French.) Leaves ovate-oblong, usually serrulated, pale green, with a winged stalk. Flowers middle-sized, red externally. Fruit oblong, very uneven, now and then almost round, with a pale yellow fragrant rind, dotted with concave cysts. Pulp juicy, and very acid. Of this species the cultivators take little pains to distinguish the varieties. When young plants are wanted they are generally raised from seeds in the orange countries, and hence the samples of fruit sent to market consist at all times of numerous sorts, differing very much in quality. Some of them have their rind so thick and insipid that they approach the citron in quality; one, with roundish rugged ribbed fruit, is called *Vignette* upon the Continent, where it is common; another, with oblong

extremely rugged fruit, is one of the *Poncires* of the French. The most distinct race is that which comprehends the *Perettes*, or little pears; they are very small in the fruit, which is a pale greenish yellow, and has almost the shape of an egg: their rind is more delicately perfumed than that of common lemons.

8. *Citrus Medica*, the Citron. (*Cedratier* of the French, *Cedro*, *Cedrato* of the Italians.) Branches short and stiff. Leaves oblong, toothed. Flowers purple externally. Fruit usually large, warted, and furrowed, with an extremely thick spongy rind, and a subacid pulp. This is an exceedingly variable species, chiefly valued for the fragrance of the rind of the fruit, from which a delicate sweetmeat is prepared. The Citron, supposed to be the Median, Assyrian, or Persian apple of the Greeks, is probably the most beautiful species of the genus. It is described by Risso as having a majestic port, shining leaves, and rosy flowers, which are succeeded by fruit whose beauty and size astonish the observer at the same time that their sweet odour gratifies his senses. The trees are constantly in vegetation, the flowers appear even in midwinter, and there is so continual a succession of them that flowers, young fruit, and ripe fruit, may always be seen together at the same moment. The Poncire Citrons are eight or nine inches long, and are the largest of the race known in Europe.

In China there is an enormous variety, with its lobes all separating into fingers of different shapes and sizes, whence its name of fingered Citron. The Chinese esteem it very much, both for its rarity and for the grateful odour of its rind. They place the monstrous fruits upon porcelain dishes, and have them in their apartments to fill the air with fragrance. Those who would study this genus in detail will find excellent figures of above 100 varieties in Risso's *Histoire Naturelle des Orangers*. A good commercial account of this interesting genus has still to be written.

For cultivation see [ORANGE.]

CITRUS AURA'NTIUM, ORANGE, of which there are two varieties, the sweet, or China orange, and the bitter, or Seville. The fruit of the latter, while small and unripe, is collected and dried; the smallest, which are of the size of a pea, are used for keeping issues open, and the larger for the preparation of the liqueur called Curaçoa. Of the ripe fruit every part is used either medicinally or dietetically. The rind, called flavedo, contains a bitter principle and much volatile oil; and either used at dessert, or reduced to powder and added to magnesia and rhubarb, furnishes a grateful tonic to the stomach in some forms of dyspepsia and gout. The pulp and juice are exceedingly agreeable to persons affected with inflammatory complaints, or a drink prepared from it (orangeade) is of great utility in bilious and gastric fevers, dysentery, &c. The roasted pulp forms an excellent application to fetid ulcers.

The peel of lemons is likewise employed, but it is not so warm and grateful as that of oranges, from containing less volatile oil. The powers of lemon juice are much increased by saturating it with chloride of sodium (common table-salt). It is then of great efficacy in the treatment of dysentery, remittent fever, the dry belly-ache, putrid sore throat, and other diseases occurring in the West Indies. Dr. Wright also recommends it in diabetes and lientery.

Citric acid exists in numerous fruits, particularly those of the orange tribe, such as the lemon and lime, either alone, or with malic and other acids; sugar, mucilage, and extractive are also present. The citric acid is separated and purified on a large scale, in the way before mentioned. [CITRIC ACID.] It is frequently adulterated with other acids, such as tartaric, sulphuric, muriatic, and oxalic, which may be detected by appropriate tests. Citric acid, when crystallized, has scarcely any odour, but a very distinct acid taste. It is soluble in cold, but more abundantly in warm water. Citric acid has the power of curdling the milk of most animals, but not the human milk.

As it is impossible to treat of citric acid apart from lemon juice, we class them together. The impression of both on the organ of taste is the same in kind, but different in degree. Concentrated citric acid is somewhat caustic, but lemon juice is gratefully acid. To imitate the natural state, citric acid is only given largely diluted. In this state it proves a pleasant drink in fevers and diseases where the temperature of the body rises above the natural standard. According to Broussais, it agrees better than any other acid with the stomach when affected with acute inflammation. It is not so pleasant as lemonade prepared from new fresh lemons, and according to the statement of Sir G. Blane, the solution of citric acid is not so efficacious in the prevention and cure of sea-scurvy as the recent lemon juice. This is attributable to the absence of the volatile oil and the bitter principle of the rind, which are valuable adjuncts to the citric acid in its action on the stomach. The utility of lemon juice in promoting the digestion of gelatinous meats, such as veal and turtle, is well known. Fresh lemon juice may be preserved in bottles in the same way as ripe fruits, by boiling the bottles in which it is contained for half an hour, first placing them in cold water, and gradually heating it, and as soon as the contents of the bottles have fallen to the temperature of the air, closing them hermetically. Where lemon juice so preserved, or fresh lemons, cannot be obtained by ships on long voyages, the dissolved citric acid, to which a portion of an alcoholic extract of lemon peel may be added at the time of using, must serve as a substitute, should any apprehensions of scurvy be entertained.

Lemon-juice is often a means of correcting acidity in the stomach, since, like most vegetable acids, it elevates the vitality of that organ, and prevents the formation of an excess of acid. On the same principle it is found to be a useful agent in elevating the powers of the stomach in the intermittent, remittent, and bilious fevers of America, many cases of which have yielded to a combination of lemon-juice, cinchona bark, and port wine. Lemon juice is often employed to rouse the stomach and nervous system after narcotic poisoning; but neither it nor vinegar should be used till all the poisonous substance is evacuated from the stomach, otherwise it increases the power of the poison.

Citric acid, as well as lemon juice, is much employed to decompose alkaline carbonates, forming therewith pleasant effervescing solutions. These taken in the act of effervescence are often of great utility in checking vomiting, and in reducing the temperature in inflammatory complaints. But in all cases of debility the employment of citric, or any other vegetable acid, for this purpose, is decidedly improper. The amount of injury done by the indiscriminate use of effervescing draughts made with a vegetable acid is incalculable. 'Were I required,' says Dr. Prout, 'to name the medicine calculated to do the most mischief, I should name the common saline draught formed of potash or soda and some vegetable acid.'

Citric acid alone is very useful in the phosphatic diathesis; it is the alkaline base in this combination which does harm. [CARBONIC ACID.]

Externally citric acid largely diluted has been beneficially employed as a refrigerating wash, in the same way as vinegar. Slices of lemon form useful applications to scorbutic and other sores, and also at the commencement of hospital gangrene.

CITTA' VE'CHIA. [MALTA.]

CITTERN (or *gittern*, or *guittern*), a musical instrument of the lute kind, mentioned by our old dramatists. [CITHARA.]

CITY. Certain large and antient towns both in England and in other countries are called cities, and they are supposed to rank before other towns. On what the distinction is founded is not well ascertained. The word seems to be one of common parlance, or at most to be used in the letters and charters of sovereigns as a complimentary or honorary compellation, rather than as betokening the possession of any social privileges which may not and in fact do not belong to other antient and incorporated places which are still known only by the name of towns or boroughs.

Sir William Blackstone is unfortunate in his attempt to define. 'A city,' he says, 'is a town incorporated, which is or hath been the see of a bishop.' (*Comm. Introd.* section iv.) But Westminster is a city, though it is not incorporated. Thetford is but a town, though incorporated, and once the seat of a bishop. Whether Westminster owes its designation to the circumstance that it had a bishop for a few years of the reign of Henry VIII., and in the reign of Edward VI., may be doubted. But there are, besides Thetford, many places which were once the seats of bishops, as Sherburn, and Dorchester in Oxfordshire, which are never called cities. On the whole we can rather say that certain of our antient towns are called cities, and their inhabitants citizens, than show why this distinction prevails and what are the criteria by which they are distinguished from other towns. These antient towns are those in which the cathedral of a bishop is found; to which are to be added Bath and Coventry, which, jointly with Wells and Lichfield, occur in the designation of the bishop in whose diocese they are situated; and Westminster, which in this respect stands alone.

A question may arise whether Manchester and Ripon will become cities, if the scheme for placing a bishop at each of them shall be carried into effect.

CIUDA'D, in Spanish, means a town, and forms a component part of several names of towns in Spain, such as Ciudad Real, the principal town of La Mancha. [CASTILLA.] Ciudadela, 'little town,' at the N.W. end of the island of Minorca, is a well-built town, with a small harbour and 7300 inhabitants. (Miñano.) [BALEARES.]

CIUDAD RODRI'GO, a town in the province of Salamanca, built on an eminence, on the right bank of the Agueda, in a fertile plain. It is fortified with a substantial wall and a ditch, and has a citadel, being a frontier fortress on the side of Portugal, from which it is about 16 miles distant. It is 55 miles S.W. of Salamanca, and on the high road to Coimbra and Lisbon. Ciudad Rodrigo is a bishop's see, and has a cathedral, which was built in 1170, and a seminary for clerical students. It is the residence of a military and political governor, and of an alcalde mayor for the administration of justice, and has 6000 inhabitants. (Miñano.) It was taken by the French under Massena in July, 1810, and retaken by Lord Wellington in January, 1812, after a siege, on which occasion he received the title of Duke of Ciudad Rodrigo.

CIVET. [VIVERRIDÆ.]

CIVIC CROWN. Among the Romans the civic was considered more honourable than any other crown. It was the recompense for the life of a citizen saved, either in battle or assault. A civic crown was conferred on Cicero for detecting Catiline's conspiracy; and afterwards upon Augustus, the reverse of many of whose coins bear the representation of it, with the inscription OB CIVES SERVATOS. This crown, which was in fact a wreath, was at first of elm, afterwards beech was used, and lastly, and most generally, oak. (Rasche's *Lexicon Rei Numariæ*.) Plutarch, in the Life of Caius Marius Coriolanus, has given what he considers to be the reasons for the choice of the oak. Pliny informs us that the civic crown was the foundation of many privileges. He who had once obtained it had a right to wear it always. When he appeared at any of the public shows, the senators rose to do him honour; and he was placed near their bench. He was excused from all troublesome duties and services; and his crown procured the same immunity for his father and his grandfather on his own side. (The reader may consult for further information, Polyb. lib. vi. c. 37; Plin. *Hist. Nat.* lib. xvi. c. 4; Tacitus, *Ann.* lib. iii. § 21; xv. § 12.)

CIVIL ARCHITECTURE. Although this term appears to imply no more than a particular branch of architecture in contradistinction to that called military, which was formerly more important than it now is in the modern system of warfare, it in reality comprises the whole of architecture considered in regard to design or as a fine art, since mere building, to whatever purpose it be applied, can never with strict propriety be so termed. Architecture includes construction, but it aims at something more—at grandeur or beauty, at exhibiting qualities and effects to which building and construction are no more than the means. Needless as this distinction may appear to be to many, persons in general, we apprehend, confound the *art* with what belongs to the science, and consequently imagine that the study of architecture concerns those only who follow it as a profession, or that it demands a knowledge of various dry and mechanical details, by which they are deterred from even approaching what they would soon discover to be attended with no more difficulty than what just serves to give excitement and to enhance the pleasure of the pursuit. Neither is its interest confined to criticism or the gratification derived from contemplating any particular building, but expands itself over the almost boundless tracts of historical research in all ages and countries wherever art has existed. It is a study, in fact, which is so intimately connected with nearly all the other arts, both ornamental and mechanical, and with the state of society, that it imperceptibly leads us to trace the progress or decline of civilization. Architecture therefore has many claims on the attention of those who can have no other inducement to study it than what it holds out in its character of a fine art and a pleasing intellectual pursuit, a character properly recognised and discriminated by the German term *Schöne Baukunst* (fine architecture), which, if adopted into our language, would at once remove that prejudice and misconception now so prevalent in regard to it.

So wide a field does the history alone of the art and its various styles embrace, that we cannot attempt to give anything like a general view of it, however rapid. Accordingly we shall confine ourselves chiefly to the Grecian style, as being that whence the Roman and Italian orders are derived, and which, so modified, prevails more or less throughout the whole of Europe, at the present day, except in those buildings, and they are comparatively few, where the Gothic is avowedly imitated. As to the question of the origin of Grecian architecture and its supposed derivation from the Egyptian style, we consider it unnecessary to make any remarks here, our object being only to explain the Grecian style and those styles which are undoubtedly derived from it.

Before we commence our remarks on Grecian architecture, it is necessary to explain that what is termed an Order consists of two principal divisions, the *Column* and the *Entablature*—*i.e.*, the upright support and the horizontal mass supported by it; the former being again divided into *Base*, *Shaft*, and *Capital* (except in the Doric order, where the shaft rests immediately upon the flooring); the latter also into three parts—*Architrave*, or Epistylium, *Frieze*, and *Cornice*. These together constitute an Order; which is further distinguished as belonging either to the Doric, or Ionic, or the Corinthian style, according to certain general proportions and characteristic embellishments. The scale for the proportions—that is, not the actual but the relative dimensions of the different parts compared with each other—is taken from the lower diameter of the shaft of the column, which is divided into two modules or sixty minutes. Modern systematizers, who have laid great stress upon proportions, have, contrary to the practice of the Greeks themselves, attempted to fix certain invariable proportions for each order; and some have maintained that by them, quite as much as by peculiarities of detail and embellishment, the character of an order is determined. In regard to proportions, however, even greater discrepancy is found between different examples of the same order, than between two distinct orders. We must therefore attend to certain indicial features and marks by which the particular order may be immediately recognized; thus the absence of base or mouldings at the bottom of the column, the plain capital composed of merely an echinus and abacus, and a triglyphed frieze, enable us to pronounce at once that the order is the Doric. In like manner the voluted capital, or the foliaged one, as distinctly denotes that it is either Ionic or Corinthian. In regard to the two last-mentioned, the principal distinction between them is confined to the capital; there being no other determinate difference between the columns of the one or the other, or in the entablatures, if we except the modillions peculiar to the Corinthian, as we find it in Roman examples. Were we to see only the shaft of the column, we should be able to decide from that alone whether it were Doric or not; the flutings peculiar to that order being broad and shallow, and forming sharp ridges or arrises on the circumference of the shafts; whereas in the other two they are narrower and deeper, rounded at their extremities, and divided from each other by fillets or spaces left between the channels on the surface of the shaft. In like manner were we to see the fragment of an architrave, we could pronounce with tolerable certainty whether it was Doric or not; although in the latter case not quite so clearly whether it was Ionic or Corinthian. The Doric architrave consists of a single plain face surmounted by a broad fillet, here termed the tænia, to which another fillet with small cylindrical guttæ or drops is attached beneath each triglyph; but the architraves of the other two orders are divided into (generally) three faces or faciæ, slightly projecting one above the other, and crowned by curved mouldings, sometimes plain, but more frequently enriched. By attending to these few simple and obvious distinctions, no one can feel any difficulty in ascertaining the particular order to which a building belongs.

Strictly speaking, only two orders were employed by the

Greeks, the Doric and Ionic; for although we have a most florid and beautiful specimen of the foliaged capital in the small structure called the choragic monument of Lysicrates, and one or two other examples, partaking more or less of the general character of what is called the Corinthian capital, yet these scanty and imperfect remains do not go far towards proving that a distinct order of the kind—of which they appear to have been only the first essays and rudiments—was recognised in their practice by the Greeks. If such had been the case, we should doubtless have found the character now marked by the capital alone more fully developed throughout.

The earliest examples of the Grecian Doric—as, for instance, that of the temple at Corinth—are marked by a massiveness of proportions approaching to heaviness, if not to rudeness; which circumstance, together with the narrowness of the intercolumns (spaces between one column and another), favours the supposition that the Greeks borrowed their first ideas of architecture from Egypt; and if this be admitted, the hypothesis of the different parts of a Grecian structure being derived from a primitive timber hut, falls at once to the ground. The following considerations also are urged against this hypothesis. Unless the aim had been to make the hut itself in the first instance resemble as nearly as possible an erection in stone, such timber model would have given rise to a much lighter style of architecture. If single pieces of timber of sufficient thickness and length for the columns could have been procured, so could they also for the architraves; nor could there have been the slightest occasion for putting the columns so close together. It will be said that we do not see the first essays in stone, which undoubtedly retained more of the character of the timber prototype, but structures wherein greater solidity had been introduced so as to render their character and proportions more conformable with the nature of the material employed. Yet as far as extant examples themselves afford any proof, the reverse of this took place; since in them we observe a progressive change from heaviness to lightness—from columns less than four diameters in height to those of nearly seven. The chief circumstance that favours the idea of the Grecian style being derived from timber construction is, that the columns are round and tapering like the stems of trees; a form not likely to have been adopted had stone been employed from the first, it being more natural that the pillars should have been square. But, it is urged, that this circumstance ought to lead us to adopt the same hypothesis in regard to Egyptian architecture; whereas by supposing that the Greeks took their first ideas from that source, perhaps all the difficulties attending the other hypothesis are removed. 'The entire character of Grecian architecture,' says Wolff, in his 'Beyträge zur Æsthetik der Baukunst,' 'as well as of Egyptian, is essentially connected with construction in stone, which alone is capable of accounting for the architectonic principles it exhibits.' In stating these opinions as to Grecian being borrowed from Egyptian architecture, it must be observed that many strong reasons are urged on the other side; and so far as there is any direct historical evidence either on one side or the other, it is in favour of the hypothesis against which we here contend. [ARCHITECTURE.]

In attentively examining the Grecian Doric, we can hardly fail to note what admirable taste and study of effect it exhibits throughout, and how every part is made to conduce to the character of the whole. The columns are of short proportions, the entablature deep; the former have no bases, which, owing to the narrowness of the intercolumns, would have proved highly inconvenient, and instead of producing an air of finish would rather have occasioned heaviness. The proportions themselves are such as to reject any addition of that kind at the lower extremity of the column, because the difference between the upper and lower diameter—which, owing to the shortness of the shaft, occasions so visible an inclination as to produce the effect of tapering upwards—causes it also to appear to spread out below in such manner that the lower extremity becomes a sufficiently wide basis. This inclination is further rendered more apparent than it would be by the outline alone of the column, owing to the lines being repeated in the fluting. The fluting, while it diminishes the heaviness, produces great variety of light and shade in every direction; and the mode of fluting peculiar to this order is admirably in unison with the expression of all the rest, the channels being wide and shallow, and separated from each other by mere ridges on the surface; both which circumstances contribute to that breadth and simplicity which pervade the other parts. No less appropriate and well imagined is the capital, which consists of little more than an echinus and deep square abacus above it; the former expanding itself out from the neck, or upper part of the column, until its diameter becomes equal to that of the foot of the column: in reality, it is something greater, but not more so than is requisite to counteract the apparent diminution caused by the greater distance from the eye. Thus harmony is kept up between both extremities of the column, verticality is restored, the projection above (as in the case of the sloping wall and coved cornice of Egyptian structures) is made to restore perpendicularity by adding just as much as had been taken away by the diminution of the shaft upwards, and a play, variety, and contrast are produced, unattainable by any other mode.

The architrave is plain and deep, well proportioned both as to the weight which it has to bear and to the column below, its average height being equal to the upper diameter or narrowest part of the column. The width of its *soffit*, or under side, is about a medium between the two extreme diameters, so that it overhangs the upper part of the shaft; yet it is not so broad as the abacus of the capital, which by opposing a greater surface to it appears better calculated to support its pressure. In Roman and Italian Doric, on the contrary, this division of the entablature is much slenderer, both as compared with the column itself and the frieze above it, and is frequently made to appear still weaker by being divided into *faciæ*, the lowermost of which is made the narrowest. In the Grecian Doric the frieze is generally of the same dimensions as the architrave, very rarely deeper, in some examples not so deep; wherein again it differs materially from the styles just mentioned. The *triglyphs* which decorate it, and are peculiar to the order itself, are upright, slightly projecting tablets (in width rather more than half the lower diameter), channelled with two grooves or glyphs (*γλυφαί*), and with a half groove chamfering off each of its outer edges. The spaces between these ornaments, which were originally intended to represent the extremities of the beams (whether stone or timber) resting upon the architrave and forming the inner roof or ceiling are square, or nearly so, and are distinguished by the name of *metopes* (*μετοπαί*): *i.e.* openings or intervals. They are in fact so many small pannels, and were generally filled with sculpture in bas-relief, although there is hardly an instance of the kind in any of the numerous modern imitations of the Greek Doric. Beneath each triglyph is a series of small *guttæ*, or cylindral drops, attached to a fillet, just under the moulding of the architrave, to which division of the entablature they may be said to belong, although evidently a continuation of the ornaments on the frieze. Some suppose them to have been intended to represent nails, others drops of water running down the channels of the triglyphs and settling beneath them; yet be that as it may, they certainly contribute in no small degree to architectonic expression and effect, inasmuch as they break the monotony of line, and by extending some ornament to the architrave bring it into harmony with the frieze. The space between one triglyph and another being regulated by the height of the frieze, since each interval or metope forms a square, this circumstance also regulates the *intercolumniation*, or distances at which the columns are placed; because as there must be a triglyph over every column, there cannot be more than one triglyph over each intercolumn, unless the latter be increased to the extent of another triglyph and metope; that is, made half as wide again. Consequently there are hardly any instances of more than *monotriglyphic* intercolumniation (that is, with more than a single triglyph over each intercolumn) in Grecian buildings, except when the centre intercolumn is made wider than the others, as in the Propylæa at Athens, where a ditriglyphic arrangement is employed.

Like every other part of the order, the Grecian Doric cornice is composed of few and bold parts; it consists of little more than a corona (the projecting and principal member in every cornice), finished above by one or two simple mouldings, and having attached to its soffit a series of shallow plates or tablets, studded with guttæ. These are termed *mutules*, and are the peculiar distinctive marks of the Doric cornice; in like manner as dentils are of the Ionic, and modillions of the Corinthian. They may be considered as being to the cornice what the triglyphs are to the frieze, and there is one corresponding to each metope as well as each triglyph; which produces a beautiful gradation of parts, for as there is an additional triglyph between every column, so is there an additional mutule between every triglyph; whereas, were there no more triglyphs than columns, and no more mutules than triglyphs, the effect would be both monotonous and poor, and these different features would be confined to distinct lines from top to bottom. The average height of the entablature is about two diameters, or one-fourth of the whole order, taking the height of the column at six diameters.

The sloping or *raking cornices* of the pediment resemble the horizontal one, except that there the mutules are omitted, although not in Roman or Italian Doric. In order, however, to give increased depth and importance to the pediment, as the finish of the whole structure, its cornices have an additional member, termed by some the *epitithedas*, consisting of an ovalo or convex moulding, or a cymatium; sometimes deeper, sometimes shallower. This *epitithedas* was continued a little way at the angles, where it usually terminated against a block, carved with a lion's head, or some other ornament. The face of the pediment itself, termed the *tympanum*, (called by the Greeks ἀετός. ἀέτωμα) was almost always filled with sculpture. The pediment was invariably of a low pitch, but not always of the same pitch; on the contrary, whatever the span might be, its height continued nearly the same, it being more or less acute, in proportion as the portico was narrow or broad: its average height was equal to that of the entablature, and either a little diminished or increased according to circumstances, but hardly ever so much as to render the tympanum deeper than the entablature.

For practical examples of this order, where the reader may study its character, and learn to distinguish, in actual buildings, the various members and particulars here pointed out, we refer to the portico of Covent Garden Theatre and the new Corn-Market, Mark Lane, in which latter the frieze is decorated with wreaths instead of triglyphs—as in the monument of Thrasyllus at Athens—and consequently the spaces between them cannot be called metopes; and the new galleries in the west wing of the British Museum.

In the Ionic order the column differs widely from that of the Doric, not only in the form of its capital, and in having a base, but in the contour of its shaft and the mode of fluting, it being more slender and not tapering so suddenly. All these differences, it appears to us, arose entirely from the form of the capital itself. Whatever may in the first instance have led to the adoption of volutes as ornaments to capitals, it is obvious that the flowing luxuriant character thus given to that part of the column required that the severity of all the rest should be mitigated, for what was graceful simplicity in the Doric would appear only offensive harshness when the capital itself was altered. In order, therefore, to restore consistency and harmony, it became necessary to reduce the bulk of the lower part of the shaft, yet at the same time to leave it sufficiently thick at bottom to prevent it from appearing top-heavy, as it must have done, had the capital expanded so much more than the foot. Consequently, in paring away the shaft, it was necessary to leave the footing of it as thick as before. Yet, had no more than this been done, the effect would have been unsightly; accordingly, the portion left as the footing of the column was formed into mouldings, termed the base, which base therefore was not, strictly speaking, added to the column, but shaped out of what remained after the part above it had been pared away. If there be any merit in this idea, we may claim it for ourselves; and although it may be deemed fanciful, not only does it appear a natural and rational process, but if we take the first or under torus of the base for the lower or prime diameter, we shall find that the Ionic column agrees very nearly with the standard Grecian Doric, of six diameters in height. The base is generally that termed the Attic-base, composed of two tori, or convex rings, with a concave moulding, the scotia, between them; for as the Doric character demands plane surfaces and lines, so does the Ionic require curved mouldings and contours, as harmonizing with the curved forms of the volutes of the capitals. To prevent the harshness which would result, if the mouldings forming the base jutted out abruptly from the lower end of the shaft, the latter is made to spread itself out immediately above the base in a sweeping curve, termed the apophyge. The number of the flutings of the shaft is increased from twenty to twenty four; besides which there are spaces left between them (fillets); for the mere arrises or sharp edges, peculiar to the Doric or earliest mode of fluting, would be utterly at variance with the rounded contours of the base and capital. The channels themselves being thus multiplied and set apart from each other, are consequently much narrower than those of the other order, and considerably deeper in proportion to their breadth; and instead of terminating in flattish curves, their extremities are made the half of a circle, or an ellipse: all which circumstances contribute to uniform delicacy of expression. It should be observed, too, that the upper torus of the base was generally fluted horizontally, thereby producing uniformity of decoration between that and the shaft, with contrast as to the mode of applying it. When not so fluted, that torus was sometimes enriched with a *guilloche*, a beautiful sort of chain-like ornament sculptured on its surface.

The capital may be described generally as consisting of two faces, about as wide, measured across the volutes, as the base—that is, a diameter and a half, or 90 minutes; which breadth is divided into three equal parts (more or less), 30 minutes being allowed for each volute. These volutes are composed of spiral mouldings, which make several revolutions, and gradually become narrower as they approach what is termed the eye or cathetus: in the richer capitals of this class there are intermediate spirals, following the course of the other; the spaces or interspirals, forming slightly concave surfaces. In all the Athenian examples there is also a flowing or festoon hem forming the lower edge of the face between the volutes, whose curve harmonizes most beautifully with the outline of the volutes themselves; whereas, in the capital of the Asiatic Ionic, as well as the Roman and modern Italian, the volutes are here connected by a straight line. Immediately beneath this part of the capital is a carved convex moulding, to which succeeds the echinus or ovolo (so called because invariably cut into the form of eggs), and lesser mouldings. The idea of an Ionic capital therefore seems to have been that of introducing an ornamental mass between the echinus and abacus of the earlier shaped capital, and rolling up its deep projecting extremities into volutes. Besides the capital (properly so speaking, where additional richness was required, and also increased height for the column, without much increasing that of the shaft), a necking, enriched with sculpture, and separated from the shaft by a carved convex moulding, was introduced. The abacus is square in plan, and its sides form a cyma reversa, or ogee moulding, either carved or plain, according as the capital itself is more or less enriched. But the capital itself, at least that portion of it occupied by the volutes, is not so deep on its sides as on the two faces; the reason for which is obvious, because either those faces must have been much narrower, or if this part formed a perfectly square mass of a diameter and a half, it would overhang the upper parts of the shaft, and project beyond the architrave in a most unsightly manner. The baluster sides of the volutes, as they are termed, are, for the sake of elegance and lightness, hollowed out so as to assume something of the appearance of two tubes or horns, whose broader extremities or mouths come against the back of the volutes. The capitals at the angles of a portico are frequently differently arranged, since, in order to obtain a face on the return similar to that in front, the outer volute is turned diagonally, so as to serve for both faces; a mode adopted for all the capitals, without distinction, by many Italian architects. The architrave is divided into three nearly equal faciæ, projecting very slightly one over the other, and crowned by a cyma recta moulding, carved or plain, as the rest happens to be more or less enriched. There being no particular members appropriated to the frieze, as in the Doric order, unless enriched with sculpture, it is a mere plain surface; but although generally so decorated by the Greeks, there is hardly an instance of it among ourselves, except in the portico of the East-India House. Examples have been found in Sicily of triglyphed friezes above columns of this order; which seems to show that the change from Doric to Ionic was progressive, and that some of the features now considered peculiar to the entablature of the former were not discarded till some time after columns with bases and voluted capitals had been employed.

The cornice in Athenian examples is exceedingly simple, consisting only of two mouldings beneath the corona, the uppermost being within the hollowed soffit of that member; nor do dentils, which are generally reckoned the distinguishing marks of the Ionic cornice, appear to have been used, except by the Asiatic Greeks. Consequently, unless the frieze is enriched with sculpture, so as along with the cornice to produce a rich ornamental mass above the architrave, not only is the cornice apt to appear meagre, but the whole entablature to look cold and naked, even plainer than that of the Doric order, and to offer anything but a pleasing contrast to the elegant richness of the capitals below it. Accordingly, when the frieze is left plain, it becomes almost indispensably necessary to give greater depth to, and bestow more ornament on, the cornice itself; which has been done, by Mr. Gandy Deering, on the front of the beautiful little church in North Audley Street, where, besides dentils and additional mouldings, there is an epithetidas or cymatium above the corona, enriched with panthers' heads.

What has already been said in regard to the pediment will suffice for this order likewise, there being no other difference than what is occasioned by the cornices themselves. But having thus far explained the two chief Greek orders or styles of columns, in regard to columns and entablatures, we now proceed to notice what in certain situations are employed as adequate to, or substitutes for, columns, namely, *antæ*, or pilasters. In Italian architecture, pilasters are very frequently employed in lieu of columns, or are placed against a wall to correspond with a range of columns in front of it; their bases and capitals, too, are made to correspond with those of the columns, as far as the difference between a square and circular plan will allow. The Greeks, on the contrary, never employed antæ, except at an angle or the extremity of a wall; and instead of aiming at perfect similarity, they purposely gave to such pilasters, bases and antæ-caps, dissimilar from those of the columns; neither did they diminish them, but made them of the same width above and below, which width was determined by that of the soffit of the architrave, and was therefore something less than the lower diameter of the column, but greater than the upper one, since both in the Doric and Ionic the architrave overhangs the upper part of the column. Thus they kept the antæ and columns quite distinct in character, thereby producing variety and contrast without injury to consistency. Sometimes the Doric anta has a simple kind of moulding and groove at its foot, which seems requisite to detach it from the wall, whereas the plain foot of the column resting on the pavement or steps defines itself to the eye quite sufficiently. The Doric anta-cap is very simple, and its abacus and other mouldings much narrower than those of the column-capital. If such were not the case, the mouldings under the abacus being square like that member, whose angles do not overhang them as they do the circular echinus, the whole would look exceedingly clumsy and coarse, and the capital be enormously wide in comparison with the anta itself; because that being no broader at bottom than above, such capital would extend very preposterously far beyond the line of the base.

Although more ornate than those of the Doric, Ionic antæ-caps differ still more than the others do from the capitals of their respective columns, inasmuch as they have nothing whatever answering to those exceedingly characteristic features, the volutes; nevertheless they are so strongly marked by the same style as to render it impossible to mistake them, or attribute them to any other order. Between the bases of the antæ and those of the columns there are very slight differences; the chief is that besides the upper torus being fluted like that to the base of the column, the under one is also enriched, but by reeding or convex mouldings. There is also an additional concave sweep moulding placed beneath the torus. It is further to be observed that antæ are never fluted, as is generally the case with Roman and Italian pilasters whenever the columns are so, and consequently a stronger distinction is kept up between the antæ and the columns; and in fact the plane faces of the former are very ill suited for such channelling, which would only produce monotony by so many parallel lines and hollows all casting the same shadow; and least of all is the Doric mode of fluting adapted to such purpose.

In the above sketch of this order we have merely pointed out in a general manner the leading characteristics, without taking notice of the very numerous varieties, since hardly any two examples are perfectly alike, and some are strikingly dissimilar from any other. One of the most remarkable is that of the internal order of the Temple of Apollo at Bassæ, near Phigaleia, in Arcadia. The base, which is altogether different from the Attic one, is of great diameter compared with the shaft, which spreads down to it with a sudden sweep; hardly less peculiar is the style of the fluting, the channels being very broad and shallow, and the fillets very narrow, while the extremities of the channel are hardly curved at all, so that it seems but the first remove from Doric fluting. The capital is still more extraordinary, inasmuch as there are four voluted faces; at least there would be, if the columns were not attached to projecting piers. In order to effect this the faces are made concave, so that the volutes turn out towards the angles, and are placed at only half the usual distance from each other, so as to reduce still more the width of each face, else, as has already been remarked, the capital being square, it would be too bulky for the column. In its detail this capital is so plain that it looks very much like one of the earliest essays at a voluted capital; nor is it improbable that at first the design was to make such capitals perfectly square like the Doric abacus and to produce four uniform voluted faces.

Another unusual variety is that of an Ionic capital, met with by Mr. Inwood among some fragments on the banks of the Ilissus, near Athens, in which the eye of the volute is remarkably large, and carved into a rosette. He has given capitals of this sort to the columns in the portico of the church in Regent-square, London; and also very singular bases. As far as the columns alone go, that portico is exceedingly well worth notice. But the finest modern specimen of Athenian Ionic is the portico of St. Pancras' church, London (also by Mr. Inwood), an exquisitely finished copy of one of the most florid specimens of the order, that of the Erechtheion. On the lateral porches at the eastern end he has given an application of Caryatides or female columnar statues supporting an entablature [CARYATIDES], after the small building called the Pandrosium, attached to one angle of the Erechtheion. Other modern examples of the Ionic order in the metropolis are, the India House, which is more Asiatic Ionic than Athenian; the portico of Hanover Chapel, Regent-street, also Asiatic, being after the order of Minerva Polias at Priene, and which exhibits also the singularly formed Ionic base; the New Post-office; the University Club-house; the Law Institution, Chancery-lane; and particularly the portico of the College of Surgeons, Lincoln's-inn-fields, as lately perfected by Mr. Barry. This last mentioned is after the small temple on the Ilissus, so deservedly admired for the bold and graceful simplicity of its contours and proportions.

In regard to *intercolumniation*, or the distances at which columns are placed from each other, and upon which so much of their effect depends, it has already been mentioned that in the Doric order this is regulated by the triglyphs, and that monotriglyphic intercolumniation may be considered as the extreme of pycnostyle (thickly set), as it will sometimes occasion the columns to be less than a diameter and a half apart, the limits assigned to pycnostyle. But this of course depends upon the proportion which the metopes and triglyphs bear to the lower diameter of the columns. That such very close arrangement should be employed for the most solid of the orders, would almost appear an incongruity; yet it should be observed that in reality this arrangement is not so close as it appears to be when expressed by the proportion which the foot of the column bears to the intercolumn, because the shafts taper so much that what would be an inter-column of less than a diameter and a half below, would be two of the upper diameters, or more, above. The second mode is termed *systyle*, or two diameters apart; the third *eustyle*, or two and a quarter; the fourth *diastyle*, or three diameters; and, lastly, *aræostyle*, or four or more diameters. But the precise spaces thus laid down do not seem to have been adhered to; and the Greeks, who seem never to have worked according to fixed rules, although precise rules have been since laid down from their works, seem to have allowed themselves any intermediate interval from a diameter and a quarter to two diameters, which they rarely exceeded, except when particular circumstances required it, and when the columns themselves were so small, that had they not been more than two diameters apart, the intercolumns would have been inconveniently narrow. When the columns are pycnostyle or less than two diameters apart, they produce richness not only by their increased number in a given space, but also owing to their being forcibly relieved by the increased depth of shadow behind them.

Simple as are the plans of Grecian temples, there are many terms required to express their varieties in regard to the application of columns, besides those denoting the number of columns in front, that is, beneath the pediment. Thus, if there were columns only in front, the building was termed *prostyle;* if at each end, *amphiprostyle;* if there were also colonnades along the sides, it was said to be *peripteral*, that is, with wings (aisles) or colonnades quite round it. When there were two rows of columns, one behind the other, it was termed *dipteral*. Again, where a range of columns was placed between antæ, forming the extremities of walls at right angles with such colonnade, it was said to be *in antis*. This was generally the case with the pronaos, the vestibule or inner portico behind the columns in front. According to the number of columns in front, porticos are said to be *tetrastyle*, that is, with four columns; *hexastyle*, with six; *octastyle*, with eight; *decastyle*, with ten; and *dodecastyle*, with twelve, the greatest number that can very well be brought beneath a pediment; and even of these two last the examples are exceedingly rare. If instead of columns at the angles there were antæ, then the number of columns alone was reckoned as before, and would denominate what would be equivalent to a portico containing two more: thus a *distyle in antis*, *i. e.*, two columns between two antæ, would be equal to a tetrastyle, as in both there would be three intercolumns; a *tetrastyle in antis* would be equal to a hexastyle, and so on. By means of this simple mode of numerical notation, a couple of words suffice to explain in the concisest manner what even a long description may leave doubtful: for instance, when we say that a portico is hexastyle Ionic, we clearly specify the order, and the number of columns in front; and it is upon this latter circumstance that so much of particular character depends. By way of example, we instance the following structures: distyle in antis, the church in North Audley-street; tetrastyle, portico of Covent-garden theatre, and Hanover Chapel, Regent-street; tetrastyle in antis, Law Institution; hexastyle, the porticos of St. Martin's; St. George's, Hanover-square; ditto, Bloomsbury; St. Pancras; Post-office; College of Surgeons; Colosseum, Regent's-park, &c. Octastyle, portico of the National Gallery; and decastyle, that of the London University: of which two latter classes these are the only instances at present in the metropolis; unless we choose to reckon the centre of the south front of the Bank as an octastyle; yet although it is a range of eight columns, they are so very little advanced from the wall behind them, that they cannot be said to constitute a portico of any kind. This example might therefore not improperly be designated a pseudo-portico. In like manner the ranges of columns in the wings of the Bank might be distinguished as screen, or pseudo-colonnades.

With us the use of the term portico is technically restricted to a range of columns crowned by a pediment, and forming an outer vestibule at the chief entrance to a building. It is not however absolutely necessary that there should be a pediment in order to entitle them to such appellation: for instance, the portico of the College of Surgeons has no pediment. When the portico advances beyond the main body of the edifice it is described as prostyle, and may be further distinguished according as the projection is made by one or more intercolumns at its sides: thus we should say that the portico of Surgeons' College is hexastyle, Ionic, unpedimented, prostyle of one intercolumn (*i. e.*, is only one intercolumn in depth); St. Martin's Church, Corinthian, hexastyle, prostyle of two intercolumns. When the columns are in antis, the portico is inclosed, though not necessarily recessed; a distinction that should be attended to if we would avoid ambiguity. For instance, St. Paul's, Covent Garden, is inclosed at its sides, but not recessed within a general line of front extending on each side of it, as is the case with the portico of the India House; which, besides being recessed, may also be taken as an example of pseudo-prostyle, inasmuch as the columns are advanced beyond the line of the rest of the front, but not so much as to constitute an intercolumn. A recessed portico is sometimes, by way of distinction, termed a loggia. We have instances also of porticos partly recessed, and partly prostyle, as that of the Post Office, which, besides advancing before the building, retires within it. Lastly may be mentioned the prostyle in antis, that is, a portico in antis enclosed at its sides, but attached and projecting from a larger mass of building, as the entrance to the Athenæum Club-house. Colonnade, on the contrary, is a general term for any range of columns. The term peristyle is often applied in the same sense, yet very inaccurately, since it denotes a colonnade continued quite round a building, as in the new Town Hall at Birmingham (at least columns are there continued along the two sides as well as the front), and the Bourse at Paris; we may also very properly speak of the peristyle of the dome of St. Paul's.

So far from employing pedestals to columns, which some have considered as forming as essential a part of an order as the entablature, the Greeks placed their columns immediately on the floor, or uppermost step; the whole temple being generally raised on a low platform, to which the ascent was usually by three deep steps, or gradini, serving as a base to the edifice; the depth of the steps was not accommodated to the human stature, but regulated so as to accord with the dimensions of the column. It is, therefore, conjectured that either a sloping platform of wood, or lesser steps of the same material, were employed as the real ascent to the temple. There are gradini of the above description to the portico of the Glyptotheca, at Munich, where a flight of steps is cut out of them, leading up to the centre intercolumn. The Greeks invariably placed their columns singly, never in pairs, as has frequently been done by modern architects, and which, if not utterly indefensible, ought never to be resorted to, unless required by positive necessity; for instance, where wider intercolumns than the scale of the order will properly admit, are required, in which case, by affording additional support to the entablature, coupled columns not only excuse the width of the intervals, but take away the air of poverty that would result from single columns placed at the same distance from each other. Coupled columns are most of all offensive when forming a prostyle colonnade, especially if it be one with a pediment, since that disposition approximates so closely to that of the front of an antient temple, as to render any incongruity the more striking. Were it, therefore, on this account alone, the portico of the new palace, St. James's Park, must be pronounced unsatisfactory: and we may remark that although it has eight columns in front, we did not cite it as an octastyle example, because the columns being in pairs, there are only three intercolumns; it may therefore be termed a double tetrastyle.

Of engaged columns, that is, columns half or three quarters of a circle in plan, and placed against a wall as if built into it, there are so very few instances in Grecian architecture, that they are to be considered merely as exceptions. One such authority for the use of half-columns occurs in the west front of the triple temple, or Erechtheion, at Athens. In the Italian, or Palladian school, they prevail almost to the exclusion of insulated columns. Yet not only is much of the effect of the columns themselves lost, but also that of light and shade. At present, columns are seldom attached, but left disengaged from the wall even when placed almost in contact with it. Attached columns have however been adopted in the Ionic hexastyle of the river front of the new Fishmongers' Hall, London, where, being surmounted by a pediment, they may be said to form a pseudo-portico. But if something like the authority of the Greeks themselves can be pleaded in support of engaged columns, it cannot be adduced as countenancing a barbarism to which that practice and the employment of wide intercolumns gave rise, namely, that of making a break in the entablature above every column, and thereby destroying the continuous horizontal line of that part of the order, and carrying the vertical ones up into it. Another practice, not observed in any extant Greek building,* is that of supercolumniation, or the placing one order upon another, sometimes even to the extent of three or more; the diameter of the columns decreasing, and of course the width of the intercolumns increasing as they ascend. Inigo Jones's building called the Banqueting-house, at Whitehall, affords an example of super-columniation, together with one of engaged columns and broken entablatures. There is also an instance of it in the New Palace, London, where a Corinthian order is placed above a spurious Grecian Doric, without triglyphs, or any division of architrave and frieze; there is still another in the recently erected Atlas Assurance Office, Cheapside.

---

* The temple of Athena Alea, at Tegea, built about B.C. 383, by Scopas, had, in the interior, a Corinthian (*κόσμος Κορίνθιος*) imposed upon a Doric order. The exterior columns were Ionic. (Pausan., *Arcad.*, c. 45.) In this passage the word *κόσμος* (cosmus) corresponds to the modern word Order.

Although the name itself would seem to show the contrary, Grecian architecture affords no precedent for what is termed an Attic order, that is, a series of dwarf pilasters crowned by a cornice; and balustrades also are of modern invention. The only thing of the kind in ancient examples, and that of exceedingly rare occurrence, is a low and plain unbroken podium, or parapet, that is, without pilasters or other projections, above the cornice of a building. Far from attempting to conceal the roofs of their temples, the Greeks not only made them very conspicuous in the outline of the pediments, but bestowed much decoration on them, ornamenting the ridges and tiles, and placing a series of *antefixæ*, or enriched front tiles, above the cornice along the sides of the building. This species of embellishment has been adopted in the church of St. Pancras; which structure also affords beautiful and correct specimens of Grecian doors and windows. The latter, which are copied from those of the Temple of Minerva Polias, forming the western portion of the Erechtheion, are almost the sole extant type in Grecian architecture for such apertures. They are surrounded by a moulded architrave, and the jambs incline towards each other, so that the aperture of the window is somewhat narrower at the top than at bottom. This peculiarity may have arisen from the difficulty of procuring single stones for the lintel or upper architrave, wide enough to extend over an aperture equal to the sill of the window; yet it may also have been adopted entirely as a matter of taste, with the view of both producing a contrast between the sloping outline of the windows, and the vertical lines of the walls and antæ; and an accordance with the tapering form of the columns. What serves to countenance this last idea is, that we find the same principle observed here as in the column itself, namely, that of restoring at the summit what had been lost by diminution upwards; for as the capital spreads out as wide as the base of the column, so is the upper horizontal lintel made as wide as the sill of the window, by means of a break towards the top of the side architraves (technically called a knee), so that the architrave expands there to the width of the sill. These remarks may perhaps be thought to partake of a minuteness inconsistent with so brief a sketch as this, where many things generally noticed in similar articles are entirely passed over; yet although it is not professed here to teach much, we are anxious to teach that little well, and to lead the reader to examine and reason upon what he sees. By doing this at the outset of his studies, he will be far better prepared to pursue them with satisfaction, than he would be by having presented to him a dry statement of more numerous particulars, which would tend only to confuse, and may therefore very well be reserved until he shall have obtained such general insight into the subject as it is our object here to supply him with.

The doorways of Grecian temples were made lofty and spacious, not only for the sake of rendering them important architectural features, but also because the light was admitted into the cella, or interior fane, usually of small dimensions compared with the general structure, through the entrance. Almost the only instance of windows in such structures is that above mentioned, and consequently the interior was imperfectly lighted, unless the temple itself was of the kind denominated hypæthral, that is, exposed to the sky (as was the Parthenon), the centre portion being left unroofed, with merely a covered colonnade, or portico around it, above whose columns were others forming a smaller order; for, as such inner peristyle consisted of columns less in diameter and height than those of the exterior one, the additional tier was necessary to fill up the greater altitude occasioned by the slope of the external roof above them. Like the windows, Grecian doorways were sometimes narrower at top than at bottom, and were embellished conformably to the character of the building. One of the most elegant specimens is that of the division of the Erechtheion, called the Temple of Minerva Polias, copied in the central doorway of St. Pancras. Besides the architrave around the aperture, there is an outer border decorated with circular ornaments termed pateræ; and the whole is crowned by a beautiful corona and highly enriched cymatium, forming together a cornice supported on consoles (scroll-like brackets).

There was never more than one doorway within the portico, or pronaos, of a temple; of course, unaccompanied by windows, which, in such a situation, should be carefully avoided. If there is more than a single large aperture behind the columns, it produces not only confusion, but a crowded appearance on a surface where breadth and repose are especially requisite. How superior the effect is of a single doorway within a portico, or at most a principal doorway and a smaller one on each side of it, must be felt by every one who compares the porticos of the London University, the Post Office, St. Pancras Church, and the Colosseum, with those of St. Martin's, the College of Physicians, the Law Institution, and, indeed, almost every other.

Though the small structure at Athens, called the Choragic Monument of Lysicrates (copied in the belfry of St. Philip's Chapel, Regent Street), furnishes one of the most exquisitely designed examples of the Corinthian or foliaged-capital order that have been preserved to us, it is almost a solitary extant instance of the application of it by the Greeks; unless we choose to reckon as such the capitals of the small columns supposed to be those of the porch of the Tower of the Winds, and which have merely a single row of leaves at bottom. It is true that some magnificent edifices belonging to this order, such as the Temple of Jupiter Olympius at Athens, were erected in Greece; but they belong to a later period, after the order had been extensively employed by the Romans, who, whether its originators or not, brought it to perfection as a distinct style; for although various single capitals ornamented with foliage have been discovered among Grecian remains, they are as dissimilar from the Corinthian style as are the degenerate imitations of such capitals which occur in Lombardic and Norman architecture. That the Romans, with whose taste for magnificence this florid species of capital well accorded, succeeded in establishing a style comprehending many varieties of it, expressive of different degrees of character up to the most luxuriant richness, is evident from the examples they have left, almost every one of which is distinguished by some peculiarity, although they all agree in certain leading points. The average height of the column is ten diameters; yet the capitals and bases being proportionably deeper, the shaft itself is not much more than eight diameters. The capital is composed of two rows of leaves (generally those termed acanthus), those of the upper row springing up from between the lower ones. There are eight leaves in each row, so arranged that one of the upper ones accords with the centre of each side of the abacus; and from the sides of this centre-leaf spring out other leaves, whence emerge the helices or spirals, placed diagonally to support the extremities of the abacus, besides lesser spirals which meet, and sometimes intertwine each other above each middle leaf. The abacus itself, which is peculiar to this order, may be described as square in its general plan, but having its sides made somewhat concave, so as to curve out towards the angles, yet not overhang the body of the capital. Thus not only is extent given without heaviness, but a most pleasing contrast is produced between the convex surface of the column and the concave sides of the abacus. The angular helices were sometimes so enlarged as to assume the form of Ionic volutes placed diagonally. This kind of capital is termed Composite, and has been reckoned to constitute a distinct order, yet very improperly, since it does not affect the general character and proportions of the whole ordinance; and if a specific name is to be assigned to each variety, which is to entitle it to be considered a class by itself, we shall have almost as many orders as there are antient examples. Even the circumstance of the shaft being fluted or plain, which occasions a more obvious dissimilarity than that observable between the Corinthian and Composite capitals, ought to occasion a formal distinction.

The Corinthian entablature differs little from that of the Ionic, except in the cornice being made richer and deeper, and the number of its members increased, in order to harmonize with the deeper capital of the columns. One of the features peculiar to it is the series of modillions or small brackets supporting the corona, besides which there are frequently dentils also; sometimes again both are omitted, although there is much ornament in other respects. Indeed, the examples of this order vary so much, not in their cornices alone, but numerous other particulars, that we cannot refer to them here, and shall therefore mention only the three principal ones, viz., the Corinthian of the Pantheon at Rome, of Jupiter Stator and the Temple at Tivoli. The first of these has been copied in the portico of St. Martin's, which, with its elevated pediment and wide intercolumns, conveys sufficient idea of the Roman style as contrasted with that of the Greeks, which is shown in the adjacent portico of the National Gallery. The second, which is one of the very richest specimens known to us, may be seen in the 'Board of Trade,' at the corner of Downing Street, London; and the third, which is an exceedingly remarkable variety, is that employed in the Bank of England, where it was first introduced. Since then it has been employed by different architects, as in the new building of St. Paul's School; and what is called the Kemble Tavern, at the north end of Bow Street: in both which instances it is fully enriched according to the original.

The Roman Doric and Ionic, of which there are but few examples extant, are both so decidedly inferior to their Grecian originals, that they may well be termed depravations of them. Such as they are, however, they have been adopted and systematized by the Italians, who have limited difference of character almost entirely to difference of ornament, there being very little distinction between them in regard to the form of the column, and the relative proportion between that and the entablature. Compared with the Grecian, the Roman or Italian Doric looks attenuated; the capital is reduced in bulk, and its ovalo is but an insignificant substitute for the Greek echinus. The character and proportions of the entablature are as much altered as those of the column, and the cornice made considerably lighter, a shallow corona being substituted for the Greek one, and additional mouldings introduced beneath it. The Ionic has been equally deteriorated by the Romans and their Italian followers; especially in the capital, the volutes of which are exceedingly small, and not only insignificant in size, but harsh and devoid of grace, harmony, and variety, in their forms. Scamozzi and many other modern architects have placed the volutes diagonally, after the manner of the angular volute in the extreme columns of a portico; but the contours themselves are so inelegant, that the effect is very different in one case from what it is in the other. Modern architects have, again, very frequently employed for this order a convex or pulvinated frieze, as it is called, which has no propriety, and little more of beauty to recommend it: an instance of such frieze, as well of the Italian Ionic generally, and its defects above noticed, occurs in the Banqueting House, Whitehall, a work once extolled as a chef-d'œuvre of architecture, but now regarded rather as a curiosity.

Of what is called the Tuscan order, there are no authentic examples to enable us to decide what it really was; but as laid down by writers of the Italian architectural schools, it is no more than a simpler variety of the Doric, with unfluted columns, and without triglyphs. The absence of the latter distinguishes, not very favourably, the entablature of the lower order in the New Buckingham Palace; consequently, if any distinction is to be made at all, that example may as justly be termed Tuscan as Doric. The portico of St. Paul's, Covent Garden, professes to be Tuscan, and answers very well to the idea of not only a plainer, but a more rude and unpolished Doric, not otherwise distinct from that style than as being less mature and complete. Or, if the degree of dissimilarity observable between the two justifies the distinction claimed for the Tuscan, or untriglyphed Doric, we ought in consistency to invent some specific appellation for the Italian voluted order with a pulvinated frieze, which bears no more than a nominal affinity to that of the Erechtheion.

If the Romans deteriorated the two Greek orders, and brought to perfection a third, of which we meet with little more than the rudiments (as contained in foliaged capitals) among Grecian remains, they likewise, by their extensive application of the arch, materially altered the system of building, and obtained greater variety, though generally at the expense of consistency. Columns frequently became no more than ornaments attached to the face of piers which support arches; while the introduction of successive tiers of arches led to the practice of *supercolumniation* (or placing order over order). The arch, again, was employed, not merely to cover apertures in walls, but was used continuously between two walls, so as to form a vaulted ceiling, whether groined or semicircular. If the area to be so covered was large and of square proportions, the walls and vault were then made circular in plan, whereby the latter became a dome. Whether the Romans invented or borrowed the arch is a point we have not room to examine, and one which, even if it could be settled beyond all doubt, would be only barren information; but it is certain that the use of it enabled them to erect works on a larger scale, and that too chiefly with brick; and it likewise led to the adoption of circular forms in plans, combined with square ones, thereby giving rise to a variety and complexity in which Greek structures are utterly deficient.

The arch, if at all decorated, springs from a kind of capital crowning the piers, termed impost mouldings; and its archivolt or external facing is fashioned like that of the architrave of the order itself, if there be any. The vertex of the arch has usually a projecting key-stone, which is frequently in the form of a large console supporting the horizontal architrave resting upon, and is so far to be considered as performing the office of a column. Instead of piers, columns alone are sometimes employed, the arch springing either immediately from their capitals, or from a square block made to resemble a detached piece of entablature (as in the interior of St. Martin's, and many of Wren's churches); which latter mode is of the two by far the more objectionable, because, in addition to the incongruity of turning arches upon columns, it renders the misapplication more evident by showing in a mutilated and disconnected form what should be the proper horizontal portion of the order. Besides which, whatever is thus placed between the spring of the arch and the column is necessarily so much taken from the height of the latter, and operates again disadvantageously by reducing the diameter of the columns, and widening the space between them.

Roman domes were generally hemispherical, and made to appear much less than that externally; whereas the Italians and other moderns have not only affected greater loftiness of contour, but have usually elevated the whole dome upon a circular basis termed its tambour, sometimes of greater altitude than the dome itself. The tambour of that of St. Paul's consists of a Corinthian peristyle, surmounted by a balustrade, besides which there is a lofty attic with windows.

In themselves both the dome and arch are beautiful features, and if discreetly and tastefully applied, do not at all contravene with the character of Greek architecture, unless that style is to be confined to the mere temple form, instead of being extended by what it is to be presumed the Greeks themselves would have availed themselves of had they been acquainted with them. The exceedingly beautiful dome of the London University proves that such feature may be made to harmonize with a pure Greek style. In regard to the arch, it is certainly inapplicable to mere doorways and windows: and the two tiers of arches behind the columns greatly impair the effect of the Bourse at Paris; yet where unusually spacious openings are required, it may be applied so as to be at once beautiful and appropriate.

In adopting the Roman orders, the Italians reduced them to strict mechanical rules, making a merit of adhering to one invariable set of proportions for each; yet this has not prevented them from innovating without scruple. Notwithstanding, too, their professed abhorrence of the caprices and anomalies of the Gothic style, they have frequently indulged in fancies the most grotesque, such as curvilinear, broken or twisted pediments, clustered pilasters, broken entablatures, lofty pedestals, columns with square blocks on their shafts, &c., together with much tasteless ornament so applied as either to be insignificant or to produce only confusion. As a sample of such vitiated taste, we may refer to Gibbs's Church in the Strand, near Somerset House, and also to Temple Bar. Somerset House itself, on the contrary, exhibits some of the best features of the Italian style, tolerably free from its alloy; nor can it be denied that where a number of windows are required, that they necessarily characterize the composition full as much as anything else. The Italian style has much to recommend it, if, while we reject its solecisms and vices, we not merely adopt what is good in it, but improve its detail from the best Greek and Roman sources. What it is capable of effecting without employing any of the orders, is shown by the Travellers' Club House, Pall-Mall, which is stamped by a simple and unpretending elegance, far preferable to many bald and insipid imitations of Greek architecture, where the resemblance extends no farther than to the columns. Having thus far explained the scheme of columnar architecture as originally practised by the Greeks, and afterwards successively altered by the Romans and modern Italians, we must leave the reader who is desirous of fuller information, to consult such works as those of Stuart, and the edition of Chambers, by Gwilt. The two small volumes on Pompeii in the Library of Entertaining Knowledge will also supply much information relative to the public and private architecture of the antients; and there is much also, both artistical and practical, in Loudon's 'Encyclopædia of Architecture.' We have not attempted to give any sketch of the history of the art, and for that reason we have not even mentioned Gothic architecture, which is reserved for a separate article. For representations and other details of the orders, the reader is referred to COLUMN, and other terms are explained as they occur in alphabetical order.

CIVIL LAW. This term is used in different senses. The Romans understood by the expression, 'jus civile,' the law, 'quod quisque populus sibi constituit.' Therefore in this Roman sense civil law may be defined to be the law of any particular nation or state. In place of this original and proper signification of the term, the expression 'municipal law' has very inappropriately been used by some English writers; and civil law, in a more restrained sense, now signifies the law of the antient Romans. [ROMAN LAW.] The term Civil law (the French *droit civil*, the German *Civil-Recht*) is still used, particularly in Germany and France, in another and limited sense, to denote the law given by the competent power of the state for regulating the mutual rights and obligations of the citizens or subjects as private persons; hence the expression 'Civil Code' (*code civil*), and among the Germans, *civil*, or *bürgerliches Gesetzbuch*. [CODIFICATION.] German lawyers therefore say that civil law is a part of private law (*privat-recht*). In this sense civil law is opposed to other branches of law, as for example, to criminal law, ecclesiastical law, &c.

CIVIL LIST, as the words imply, was formerly the name given to the list of all the expenses of the civil government of the country, or of all the heads of public expenditure, excepting those of the army, the navy, and the other military departments. Originally in this country all the expenses of the government, the military expenses not excepted, were comprehended in one general list, and defrayed out of what was called the royal revenue. For a considerable period after the Conquest the royal revenue was derived from the rents of the crown-lands, and from other sources which were at the command of the crown through the exercise of the prerogative. Both the collection and the expenditure of the whole were under the uncontrolled management of the king. Even when at a later period the greater portion of the expenses of the government came to be granted by parliament in the form of supplies, the entire expenditure was still left with the crown, the supplies being either voted for no specific purpose, or when it was otherwise, no responsibility as to the application of them being enforced.

This state of things continued to the Restoration. A distinction was then made between the military expenses of the government, or those occasioned by the wars in which the country might be involved, and which were considered of the nature of extraordinary expenses, and those incurred in the maintenance of the ordinary establishments of the country. The revenues appropriated to the latter were called the hereditary or civil-list revenues, and were provided for partly from the crown lands that remained unalienated, and partly from certain taxes imposed by parliament expressly for that purpose during the life of the reigning king. The civil list thus obtained amounted, during the reign of William III., on an average of years, to the annual sum of about 680,000*l.* Out of this sum were paid the expenses of the royal household, of the privy purse, of the maintenance and repairs of the royal palaces, the salaries of the lord-chancellor, of the judges, of the great officers of state, and of the ambassadors at foreign courts; the incomes of the members of the royal family, and many other pensions, the secret service money, and a long list of other claims. The interest of the national debt however was never defrayed from the sum allotted for the civil list. In the reign of Queen Anne the civil list remained of nearly the same amount as in that of King William, the principal taxes appropriated to it being an excise of 2*s.* 6*d.* on the barrel of beer, which produced about 286,000*l.* per annum, a tonnage and poundage duty which produced about 257,000*l.*, and the profits of the post-office, from which about 100,000*l.* was derived. At the commencement of the reign of George I., 700,000*l.* a year was voted by parliament for the civil list, and certain taxes, as usual, were appropriated to that branch of the public expenditure. The same duties were, on the accession of George II., continued for that reign, it being provided that if they did not produce 800,000*l.* per annum, the deficiency should be made up by parliament, and that any surplus beyond that sum should be retained by the crown. At the accession of George III. the sum of 800,000*l.* was again voted by parliament for the civil list, but no particular taxes were set apart to provide that revenue. In the course of a few years however a large amount of debt had accumulated in this department, and to pay it off, two sums amounting together to considerably above 1,000,000*l.* were voted by parliament in 1769 and 1777. In the latter year also the civil-list revenue was permanently raised to 900,000*l.* This however did not prevent further deficiencies, which were again made good by parliament in 1784 and 1786, to the extent of about 270,000*l.* In 1780 Mr. Burke brought in his bill for the better regulation of the civil list, which, although it was greatly mutilated before it passed into a law (in 1782), abolished several useless offices, and effected some reduction of expenditure. According to the report of a committee of the House of Commons which sat upon the subject of the civil list in 1802, the total average annual expenditure in that branch since 1786 had been 1,000,167*l.*, under the following heads:—royal family in all its branches, 209,988*l.*; great officers of state, 33,279*l.*; foreign ministers, 80,526*l.*; tradesmen's bills, 174,697*l.*; menial servants of the household, 92,424*l.*; pensions, 114,817*l.*; salaries to various officers, 76,013*l.*; commissioners of the treasury, 14,455*l.*; occasional payments, 203,964*l.* At this time another sum of above 990,000*l.* was voted by parliament to pay the debts on the civil list; and in 1804 the civil-list revenue was raised to 960,000*l.* In 1812 it was further augmented to 1,080,000*l.*; besides which, annuities to the amount of 260,000*l.* were then paid to the different branches of the royal family out of the consolidated fund. Another committee of the House of Commons inquired into the subject of the civil list in 1815, and it was upon the report made by this committee that the amount of the civil list was settled, on the accession of George IV., at 850,000*l.* per annum, 255,000*l.* of annual charge being at the same time transferred from this branch to other funds. It was calculated that the distribution of this sum would be under the following heads. 1. His Majesty's privy purse, 60,000*l.* 2. Allowances to the lord-chancellor, judges, and speaker of the House of Commons, 32,956*l.* 3. Salaries, &c., of his Majesty's ambassadors and other ministers, salaries to consuls, and pensions to retired ambassadors and ministers, 226,950*l.* 4. Expenses, except salaries, of his Majesty's household in the departments of the lord steward, lord chamberlain, master of the horse, master of the robes, and surveyor-general of works, 209,000*l.* 5. Salaries in the above departments, 140,700*l.* 6. Pensions limited by Act 22 Geo. III., c. 82, 95,000*l.* 7. Salaries to certain officers of state, and various other allowances, 41,306*l.* 8. Salaries to the commissioners of the treasury and chancellor of the exchequer, 13,822*l.* 9. Occasional payments not comprised in any of the aforesaid classes, 26,000*l.* The crown was left besides in the enjoyment of the hereditary revenues in Scotland, amounting to about 110,000*l.* per annum; and also of a civil list for Ireland, of 207,000*l.* On the 15th of November, 1830, immediately after the accession of his present Majesty, William IV., Sir Henry Parnell carried in the House of Commons a motion for appointing a select committee to inquire into the civil list. The chief object proposed was the separation of the proper expenses of the crown from all those other charges which still continued to be mixed up with them under that title. The consequence of the success of this motion (besides the overthrow of the Wellington administration and the introduction of the Reform Bill) was another report, upon which was founded the Act 1 Will. IV., c. 25, by which the present civil list was settled. The committee having recommended that the civil-list charges should be confined to expenses proper for the maintenance of their Majesties' household, it is enacted that the sum of 510,000*l.* be granted to his Majesty, under the following classes. 1. For their Majesties' privy purse, 110,000*l.* 2. Salaries of his Majesty's household, 130,300*l.* 3. Expenses of his Majesty's household, 171,500*l.* 4. Special and secret service, 23,200*l.* 5. Pensions, 75,000*l.* The Irish separate civil list is also discontinued; and it is ordered that the Scotch hereditary revenues, as well as the droits of admiralty, and the 4½ per cent. duties, shall be paid into the exchequer for the use of the public. His Majesty also retains the revenues of the duchies of Lancaster and Cornwall, which are considered to be the hereditary revenues, not of the crown, but of the dukedoms of Lancaster and of Cornwall; the former of which is permanently annexed to the crown, and the latter belongs to the crown when there is no Prince of Wales. No account of the amount of these revenues has ever been laid before Parliament; but it is understood not to be considerable. In his speech on the Economical Reform in 1780, Mr. Burke said, 'Every one of those principalities has the appearance of a kingdom, for the jurisdiction over a few private estates; and the formality and charge of the Exchequer of Great Britain, for collecting the rents of a country squire. Cornwall is the best of them; but when you compare the charge with the receipt, you will find that it furnishes no exception to the general rule. The Duchy and County Palatine of Lancaster do not yield, as I have reason to believe, on an average of twenty years, 4000*l.* a year clear, to the crown. As to Wales, and the county palatine of Chester, I have my doubts whether their productive exchequer yields any returns at all.' 'There is no real reduction in this arrangement,' says Sir Henry Parnell ('on Financial Reform,' 4th edit., p. 205), 'below the grant to his late Majesty; for whatever appears to be a reduction, has been produced by a transfer of charge from one head to another of the old civil list. The chief difference in this arrangement from the former consists in the transfer of about 460,000*l.* a year from the civil-list to the consolidated fund, and in providing for the gradual reduction of the pensions to 75,000*l.* a year.' It is evident from this account, that what is now called the civil-list has no proper claim to that title. (See Sir John Sinclair's *History of the Revenue;* Colquhoun's *Wealth, &c. of the British Empire;* Sir H. Parnell on *Financial Reform;* and *Reports of Committees of the House of Commons in* 1802, 1803, 1804, 1808, 1812, 1813, 1815, 1819, and 1831.)

CIVILIZATION. The majority of mankind pay an habitual veneration to words, and this species of adoration is not exempt from fanaticism. It would not be difficult to find men who would willingly suffer any privations and tortures, and even death, for the sake of certain words. If you tell them (what indeed few people seem to comprehend) that words are but signs which give consistency and permanence to our ideas, and if you ask them what the ideas are which these words of such frequent occurrence in their conversation or writings are designed to express, you may be convinced that the art of speaking with propriety is, as it has been well remarked, inseparable from the art of thinking correctly, and that it is almost always for want of attaching the same ideas to the same words that men misunderstand each other, dispute, and sometimes come to blows.

The words civilization, education, and religion, with a multitude of others, are among those expressions which are so often used without any clear, definite, or precise ideas being attached to them; yet there are no words that require to be more thoroughly analyzed.

The meaning of a word is often formed by degrees, and in connexion with facts and observation. As soon as a particular fact presents itself to our notice which appears to have a specific relation to a known term, it becomes immediately incorporated with it; and hence the meaning of every term gradually extends itself, and finally embraces all the various facts and ideas which seem properly to belong to it. On this account, there is more depth as well as correctness and accuracy in the usual and ordinary meaning of complex terms than in any definitions which can be given of them, notwithstanding the latter may appear at first sight to be more strict and precise. In the majority of instances scientific definitions are much too narrow, and owing to this circumstance they are in reality frequently less exact than the popular meaning which is given to terms; it is therefore in its popular and ordinary signification that we must seek for the various ideas that are included in the term Civilization.

Now, the first fact which this word seems to carry with it (and many proofs of it could easily be given) is that of a progressive movement, of a gradual development, and a tendency to amelioration or perfection. It always suggests the idea of a community which is advancing, not in disorder or without design, rule, or guide, but cautiously, methodically, and with distinct and clear views of the objects which it seeks to attain; progress, continual improvement, advancement towards perfection (although the latter is obviously unattainable by man), is therefore the fundamental idea contained in our notion of the term Civilization.

Then as to this progress, improvement, and gradual advancement, to what do they apply? The very etymology of the word answers the question in the clearest and most satisfactory manner. From this we learn that it does not contemplate the actual number, power, or wealth of a people, but their *civil* condition, their social relations, and intercourse with each other. Such then is the first impression which arises in our mind when we pronounce the word *Civilization.* It seems to represent to us at once the greatest activity and the best possible organization of society; so as to be productive of a continual increase, and of a more equable distribution of its wealth and power among its members, whereby their absolute and relative condition is kept in a state of constant improvement.

But is this all? Does this explanation exhaust the entire and full meaning of the word? Does it contain nothing beyond this? It is as though we were to ask whether the human race were no more than a vast ant-hill, a community bent upon nothing but mere order and the supply of its physical wants; and where, in proportion as the labours were great and the results of them fairly apportioned, the desired end was fully accomplished.

Now great as is the influence which a well-planned organization of civil society must necessarily have upon the happiness of the human race, the term Civilization seems to convey something still more extensive, more full and complete, and of a more elevated and dignified character, than the mere perfection of the social relations, as a matter of order and arrangement. In this other aspect of the word it embraces the development of the intellectual and moral faculties of man, of his feelings, his propensities, his natural capacities, his tastes, and his ideas.

But here we touch upon the question of education, which is the very soul of civilization, which is talked of and lauded by all, though in reality understood by few.

Education, which is the result of a well-ordered social arrangement, and also its perfector and conservator, an education which shall give to every member of the community the best opportunities for developing the whole of his faculties, is the end which civilization, or a society in a state of continued progress, must always have in view. But this subject requires a separate and a much more extensive investigation.

The fundamental ideas, then, contained in the word Civilization are—the continual advancement of the society in wealth and prosperity, and the improvement of the man in his individual capacity.

When the one proceeds without the other, it is immediately felt that there is something incomplete and wanting. The mere increase of national wealth, unaccompanied by a corresponding knowledge and intelligence on the part of the people, seems to be a state of things premature as to its existence, uncertain in its duration, and insecure as to its stability. We are unacquainted with the causes of its origin, the principles to which it can be traced, and what hopes we may form of its continuance. We wish to persuade ourselves that this prosperity will not be limited to a few generations, or to a particular people or country, but that it will gradually spread, and finally become the inheritance of all the people of the earth. And yet what rational expectation can we entertain of such a state of things becoming universal? It is only by means of education, conducted upon right principles, that we can ever hope to see true national prosperity attained, and rendered permanent. The development of the moral and intellectual faculties must go hand in hand with the cultivation of the industrious arts; united, they form the great engine for civilizing the world.

In fact, without the union of these two elements, civilization would stop half way; mere external advantages are liable to be lost or abused without the aid of those more refined and exalted studies which tend to improve the mind, and call forth the feelings and affections of the heart. In a word, civilization consists in the progressive improvement of the society considered as a whole, and of all the individual members of which it is composed.

CI'VITA, an Italian appellation derived from the Latin civitas, 'a town,' forms part of the name of several Italian towns, such as Civita Castellana, a town in the province of Viterbo, near Rome, with a citadel and a bishop's see, and 1800 inhabitants; also Civita Ducale and Civita di Penne in the Abruzzo, &c. There are several places called Civitella or little town, the most known of which is Civitella on the Tronto, a fortified place on the frontiers of Abruzzo, towards the papal province of the Marches. There is also Cividal (a corruption of Cività) in the Friuli.

CI'VITA VE'CCHIA, a town and sea-port in the Papal State, in the Delegazione, or province of Viterbo. Its harbour is formed by two piers of marble blocks first raised by Trajan, who had a country residence here called Centum Cellæ, and afterwards restored under the popes. At the entrance between the extremities of the two piers is a small island or breakwater formed of large pieces of rock thrown into the sea, under the reign of the same emperor. Pliny the younger (*Epist.* 31) describes the manner in which the breakwater and the piers were made. There is from 14 to 18 feet depth of water in the harbour, which is the only safe one on the south coast of the Papal State, and is frequented by about 1000 vessels of various sizes, most of them coasting vessels, in the course of the year. There is a lazzaretto for ships coming from infected countries. There are also docks and a prison for galley-slaves. The lighthouse and the citadel were built by Michel Angelo. The present town of Civita Vecchia was built by Pope Leo IV., and is regularly fortified. The streets are regular and the houses well built. The town has a cleanly and bustling appearance. The air, although not very good in summer, is not altogether unwholesome, but the country around is subject to the malaria, and has a desolate appearance like the rest of the lowlands on this coast. The population of Civita Vecchia is about 8000 (Calindri, *Saggio Statistico*). It has a military governor, and is subject in civil matters to the delegate residing at Viterbo. Civita Vecchia is 36 miles north-west of Rome.

CLACKMANNAN, a very small county in the eastern part of Scotland; bounded on the south by the river Forth, on the north and west by Perthshire, and on the east by Perthshire and Fifeshire. Its greatest length from N.W. to S.E. is about nine miles, and its width from N.E. to S.W. about eight miles. The area is 48 square miles, or 30,720 acres, which is divided into four parishes. The surface in the southern part, adjacent to the Forth, consists of level alluvial tracts, which are very productive in corn, and contain good pastures. Towards the northern extremity the land rises gradually into the Ochill Hills, which traverse the county from S.W. to N.E., and furnish some pasturage for sheep. The woodlands cover about 500 acres, and at least 2000 acres are laid out in plantations. Agriculture is in a state of continual improvement; lime manure and thrashing machines are used on almost every farm. The highlands in the N.E. of the county yield an abundant supply of several valuable minerals. The annual produce of coal is about 130,000 tons. There are also quarries of freestone, granite, and iron-stone which contains from 20 to 30 per cent. of iron. Silver, lead, copper, cobalt, antimony, arsenic, agates, pebbles, and topazes, have been found, but not in sufficient quantities to defray the expense of working. Several excellent roads intersect the county, and there are numerous creeks along the Forth which are used by the fishermen. The chief harbours are those of the two principal towns of the county, Alloa and Clackmannan. The population in 1831 was 14,729. Clackmannan and Kinross together send one member to the House of Commons.

CLA'DIUS, a genus of Hymenopterous insects of the family Tenthredinidæ. Technical characters:—Antennæ about the same length as the body, ciliated beneath, and nine-jointed; the two basal joints short, the third joint with a protuberance beneath at the base, and a branch thrown out from the upper side at the apex; the fourth and fifth have likewise the last-mentioned process; and in the sixth and seventh it is rudimentary. In the female all these processes are wanting, excepting the one on the underside of the third joint. Wings with one marginal and three sub-marginal cells; tarsi simple.

Cladius difformis, when the wings are expanded, measures in width about one third of an inch: it is black, with the tibiæ and tarsi pale yellow. This species may be considered the type of the genus; it inhabits this country, but is not common.

CLADOBATES. [TUPAIA.]

CLAGENFURTH, a circle in the eastern division of the Austrian duchy of Carinthia (formerly Lower Carinthia), and in the north-east part of the kingdom of Illyria, is bounded on the north and east by Styria, and contains about 1500 square miles, 9 towns, 14 market-towns, 1616 villages, and 27,000 houses. Although very mountainous, and traversed by the Alps both in the interior and along the frontiers, its valleys are extremely fertile, and produce corn, fruits, and flax. The declivities of the mountains are clothed with rich woods. There are above 732,121 yochs (about 488,000 acres) of arable land. The Drave in its course through this circle receives the Glan, Gurk, Lavant, Fella, Wiesbach, and many smaller mountain streams. The largest lake is the Worth, or Lake of Clagenfurth, which is about ten miles in length, and supplies the canal leading to the chief town, Clagenfurth. The principal mountains of the southern chain are the high Loibel (4300 feet) and the Great Predl of the northern chains, the Eisenhut, and the Gruftkogel. The air is pure and salubrious, but in the mountainous districts Cretins, or as they are here called Fexes, are frequently met with. Minerals are very abundant, especially silver, lead, and iron. According to an average return of ten years, the annual produce of silver is 155 marks; lead, 982 cwt.; litharge, 165 cwt.; iron, 9730 tons; alum, 339 cwt.; quicksilver, 33,600 lbs. (according to others as much as 168,000 lbs.) Next to agriculture, mining and smelting are the most important resources of the inhabitants; there are in this circle 1 silver, 1 copper, 3 lead, 4 iron mines, 2 quarries of marble, and 2 coal-pits, besides numerous smelting houses, &c. The population in 1813 was 162,759: at present it amounts to about 180,000 inhabitants.

CLAGENFURTH (in Carinthian, Zelany), the capital of the duchy of Carinthia, in the circle of Clagenfurth, is situated on the river Glan, in an extensive plain, bounded on the south by the snow-topped mountains of Carinthia, and at an elevation of 1554 feet above the sea. It is the residence of the bishop of Gurk, and the seat of the court of appeal for the province of Laibach. Its modern name has been sometimes derived from Claudia or Claudisorum, from the emperor Claudius—hence Cladenfort, then Clagenfort, and subsequently its present designation. The town was the property of the crown till 1518, when the emperor, Maximilian I., gave it to the state of Carinthia for the purpose of erecting a fortress for the defence of the country. Soon afterwards the canal from the lake Worth, or lake of Clagenfurth, to the town (nearly three miles in length) was opened at the expense of the citizens, and the fortifications extended as the town was enlarged—especially after the great conflagrations in 1535, 1723, and 1796, to which the town is indebted for its present fine and regular appearance. The ramparts, gates, and ditches were levelled in 1809. It is in the form of a square, and is adorned with many handsome public buildings, the palaces of Princes Rosenberg and Porçia, and of the prince bishop of Gurk; which last contains fine collections of paintings, minerals, &c. There are five public squares, three of which are embellished with monuments—one a statue in lead of Maria Theresa, and an obelisk erected by the bishop of Gurk in honour of the Emperor Francis I., on occasion of the peace of Presburg. The other buildings of note are the Burg and the house of assembly, the law courts, the lyceum and library, a gymnasium, and one theatre. There is also an Ursuline convent, a normal school, an agricultural society, two hospitals, infirmaries, a lunatic asylum, a house of industry, a workhouse, and house of correction. Of the seven churches in the town, the civic church is remarkable for its fine bold tower, the gallery of which commands an extensive prospect over the town and its picturesque environs. The population is about 9300; many of whom are engaged in manufactures, particularly fine woollens, silks, and white lead. There is also a considerable transit trade. 46° 36′ N. lat., 14° 20′ E. long. In the vicinity are the baths of St. Leonhard, 3540 feet above the sea, at the foot of the chain which separates the circle of Clagenfurth from that of Villach: they are cold, and excite an appetite.

CLAIRAUT, ALEXIS CLAUDE (sometimes spelt Clairault; we have taken the spelling from the title of his own works), was born at Paris, May 7, 1713. His father, John Baptist Clairaut, was a teacher of mathematics. The early proficiency of the son in mathematics is better attested than in any other similar case, by the actual appearance of his celebrated treatise on Curves of Double Curvature, in 1731, when he was eighteen years of age, accompanied by the usual official recommendations, which prove that it was ready for the press two years before: it is said to have been begun when he was only thirteen years old. He read the Conic Sections of De L'Hôpital, and also the 'Infiniments Petits' of the same author, when he was only ten years old; a fact which we should have forborn to state, had it not been for the evidence contained in the treatise just cited, and in this fact, of public notoriety, that at the age of twelve years he presented a memoir on some remarkable curves to the Academy of Sciences, and removed all doubts as to its authorship by his personal explanations.

In 1731, being then under the legal age, Clairaut was admitted into the Academy of Sciences. He formed an intimate acquaintance with Maupertuis, and commenced at this period his researches on the figure of the earth. In 1735 he accompanied Maupertuis, Camus, Lemonnier, &c., in their expedition to Lapland, for the purpose of measuring a degree of the meridian. (See the articles connected with the Figure of the Earth.) This measure has frequently been considered as of little value: it must however be remarked, that such an opinion has been formed on the strength of discrepancies which were sufficiently apparent to the measurers themselves, and which caused them to review all their operations; as also, that circumstances connected with local attractions are fully sufficient to explain the whole difficulty. The work of Clairaut on the Figure of the Earth appeared in 1743, and was reprinted in 1808. It contains the remarkable discovery which is usually called Clairaut's Theorem. Considering the earth as an elliptic spheroid, it should seem that the variation of gravity on the surface would depend upon the law of density of the interior strata. But Clairaut showed that this variation is altogether independent of the law of density, and may be deduced from a knowledge of the form of the exterior surface. In this theorem, the second and higher powers of the eccentricity are rejected. Mr. Airy (in an early volume of the 'Cambridge Transactions') has shown that it remains true when the higher powers are taken into account.

In 1750 Clairaut gained the prize of the Petersburg Academy for his paper on the Theory of the Moon. It is more essential for us here to state the position which he occupies among the successors of Newton, than to enter into details which are better suited to other articles. Newton had left one prominent point of the lunar theory altogether unexplained by his theory of gravitation, namely, the motion of the lunar apogee, of which, though able to assign a sufficient reason for the phenomenon of progression, he was not able to deduce more than half the quantity of the phenomenon. Clairaut at first concluded that the law of gravitation was incompletely expressed; but further consideration, and more extensive application of analysis, showed that the whole motion was a necessary consequence of the Newtonian supposition of mutual attraction. In two points of view, therefore, as the first who applied what is now called the modern analysis to the problem of the lunar motion, and as the first who added an unexplained phenomenon to the theory which Newton had left, Clairaut stands in a conspicuous position.

Clairaut was the first who applied the Newtonian theory to the motion of comets, in reference to the perturbation of their motions by the attraction of the planets. In 1757 astronomers began to expect the fulfilment of Halley's prediction relative to the comet whose appearance has now once more excited public curiosity. Lalande proposed to Clairaut to undertake the actual computation of the quantity of Jupiter's action on the comet during a revolution, and offered his assistance in the drudgery of the work. For the manner in which this enormous labour was executed the reader may consult the article 'Halley's Comet,' in the 'Companion to the Almanac for 1835.' The result was that Clairaut's prediction came very near the truth; the return of the comet was at first placed in November, 1758; in that month Clairaut predicted that it would arrive at its nearest point to the sun about April 13, 1759, stating that he might possibly be wrong by a month. The observed perihelion of the comet was on the 13th of March. The error would have been considerably less if the existence of Uranus, and a more correct value of the mass of Saturn, had been known.

The figure of the earth, the theory of the moon, and Halley's comet, are the three prominent points on which the fame of Clairaut rests. We might mention his work on Geometry, drawn up, it is said, for the use of Madame du Chastellet: his Elements of Algebra, remarkable at the time for the abandonment of the dogmatical form in which it was customary to write elementary works; and many papers in the Memoirs of the Academy, containing several remarkable discoveries in pure mathematics. But we shall pass on to some notice of his career in connexion with that of D'Alembert. These two great men were rivals in their scientific labours, and though their disputes never passed the bounds of courtesy, the life of each, with respect to the other, was either armed truce or open war. The characters of the two were essentially opposite: Clairaut was a man of the world, of high polish, and who took great care never to offend the self-love of any one: D'Alembert was blunt and rude, though essentially well-meaning and kind; if we may use such a colloquial phrase, he 'stood no nonsense;' *j'aime mieux être incivil qu'ennuyé* was his avowed maxim. Clairaut was always in the world, desirous to shine, and to unite the man of fashion with the philosopher, of all which D'Alembert was the reverse. The attacks usually came from the latter, confined entirely to the writings of his opponent: and he was frequently right, being a thinker of a more safe and cautious order than Clairaut, who was more than once too hasty. For instance, when Clairaut took the whole revolution of Halley's comet, or more than fifty years, as the unit of which the error committed by him should be considered as a fraction, D'Alembert asserted that the magnitude of the latter should be compared, in the estimation of precision, with the difference between two successive revolutions, or about a year and a half. Later analysts, and Laplace in particular, have considered that D'Alembert was right. The preceding comparison is drawn from Bossut (*Hist. des Math.*), who was the personal friend and the decided eulogist of both. He adds that the polished character of Clairaut procured him an *existence* and a consideration in the great world which talent alone would not have sufficed to gain; and more than insinuates that dissipation destroyed his constitution. However this may be, Clairaut died at Paris, May 17, 1765, at the age of fifty-two. He was never married: his father (who survived him a short time) had a very numerous family, of whom only one daughter survived. (See the Eloge in the Memoirs of the Academy; the Life, by Lacroix, in the *Biog. Univ.;* and the work of Bossut, above cited.)

The works of Clairaut, independently of Memoirs presented to the Academy, are—1. 'Recherches sur les Courbes à double Courbure;' Paris, 1731. 2. 'Elémens de Géométrie;' Paris, 1741; and various editions up to 1765. 3. 'La Figure de la Terre déterminée' &c. (Account of the Lapland Measure, by Maupertuis, Clairaut, &c.); Paris, 1738; in Latin, by Zeller; Leipzig, 1742. 4. 'La Théorie de la Figure de la Terre;' Paris, 1743; again in 1808. 5. 'Elémens d'Algèbre;' Paris, 1746; again in 1760 ('très estimée,' Lacroix); again in 1797 and 1801 (marked sixth edition), by Garnier, with a Preliminary Treatise on Arithmetic. 6. 'Théorie de la Lune;' St. Petersburg, 1752, (prize essay) second edition, 1765. 7. 'Tables de la Lune,' &c.; Paris, 1754, republished with (6.) in 1765. 8. 'Théorie du Mouvement des Comètes;' Paris, 1760; the account of the great process relative to Halley's comet. D'Alembert wrote against this in the 'Journ. Encycl.,' February, 1761; Clairaut replied in the 'Journ. des Sav.,' June, 1761. 9. 'Recherches sur la Comète,' &c., St. Petersburg, 1762, (Supplement to 8). 10. 'Explication des Principaux Phénomènes, &c.;' compiled by Madame du Chastellet from Clairaut's instructions, and printed at the end of her translation of Newton; Paris, 1759. [CHASTELLET, MADAME DU.]

CLAIRVAUX, a small town in France, in the department of Aube, and on the left bank of the river Aube. It is surrounded by woods and mountains, which were once the property of the Cistertian abbey, one of the most antient and renowned of that order. This abbey was founded, A.D. 1115, by a detachment of the religious of the abbey of Cîteaux, the chief establishment of the order, under St. Bernard. The possessions of the abbey, which comprehended the wild and once uncultivated valley of Absinthe, in which it was situated, were originally due to the liberality of Hugues, count of Troyes, the first benefactor of the establishment. They were augmented by others to such an extent, that at the time of St. Bernard's death (A.D. 1153) the abbey of

Clairvaux contained five hundred monks, or, according to other statements, seven hundred. In the middle of the last century there were only about fifty or sixty monks, twenty lay brethren, and forty servants, or thereabouts. The abbey had depending upon it, previous to the French revolution, eighteen regular abbeys of men and twenty-eight of women, and forty-one abbeys held in commendam, all in France; besides forty abbeys, whether of monks or nuns, in foreign countries. The revenue of the monastery was 90,000 livres, or about 3750*l.* The church was deemed a chef-d'œuvre, and there was a gallery with some good paintings. The abbey is now used as a house of correction, in which 2000 prisoners are employed in the manufacture of different stuffs. A famous tun, 'the tun of St. Bernard,' said to contain eight hundred tons of wine, is still preserved.

Glass and paper are made in the town of Clairvaux, beer is brewed, and iron is wrought. (Expilly; Reichard; *Dictionnaire Universel de la France.*)

CLAKIS. [Bernicle Goose.]

CLAMECY, or CLAMENCY, a town in France, in the department of Nièvre, at the junction of the Beuvron with the Yonne, 110 miles S.S.E. of Paris in a direct line, in 47° 27′ N. lat., and 3° 30′ E. long. The population of Clamecy amounted in 1832 to 4926 for the town itself, or 5539 for the whole commune. Considerable trade is carried on, and the town is considered wealthy in proportion to its size. Earthenware and woollen cloth are the chief manufactures; to which we may add leather, paper, and gloves. The woollens are manufactured of the wool grown in the neighbourhood, mingled with that of Bourgogne. The surrounding country is fertile in grain and pasturage. Clamecy is the place from which the Yonne is employed for floating timber down to Paris; the navigation does not commence till near Auxerre, which is many miles lower down the stream.

Clamecy is the capital of an arrondissement, which contained, in 1832, 70,381 inhabitants.

CLAN, in Gaelic *Clann*, which is said to signify children or descendants. The word has been long adopted as English. Milton says,

'.They around the flag
Of each his faction, in their several clans,' &c.
Par. Lost, ii. 901.

The clans of the Highlands of Scotland are families, or rather tribes, all the members of which bear the same surname, and are supposed to be descended from a common ancestor, of whom the chief of the clan is the lineal representative. 'Being divided,' says Camden, speaking of the Scotch Highlanders, 'into families, which they call clans, what with plundering and murdering, they commit such barbarous outrages, that their savage cruelty hath made the law necessary which enacts, that if one of any clan hath committed a trespass the rest shall repair the damage, or whoever of them is taken shall suffer death.' Some clans however are divided into several branches, each of which has its particular surname. According to Colonel Stewart, in his 'Sketches of the Character, Manners, and Present State of the Highlanders of Scotland' (2 vols. 8vo. Edinb. 1822), p. 24, this surname, peculiar to the branch, is called the *bun sloine*, that is, the genealogical surname, being derived from the Christian name or other designation of the ancestor of the branch. It is the name generally used in common conversation; but every Highlander in writing his signature, and also for the most part when he has to mention another person in writing, uses the name which is common to the whole clan. Most of the Highland noblemen and gentlemen have designations peculiar to them as chiefs of their clans, which in their own country no feudal titles or distinctions, however exalted, are allowed to efface. 'Besides his ordinary name and surname,' says Sir Walter Scott (note to *Lady of the Lake*, canto ii.), 'which were chiefly used in the intercourse with the lowlands, every Highland chief had an epithet expressive of his patriarchal dignity as head of the clan, and which was common to all his predecessors and successors, as Pharaoh to the kings of Egypt, or Arsaces to those of Parthia. This name was usually a patronymic, expressive of his descent from the founder of the family. Thus the duke of Argyle is called Mac Callum More, or the *Son of Colin the Great*. Sometimes however it is derived from armorial distinctions, or the memory of some great feat: thus Lord [illegible]aforth, as chief of the Mackenzies, or Clan-Kennet, bears [illegible]pithet of Caber-Fac, or *Buck's-Head*, as representative of Colin Fitzgerald, founder of the family, who saved the Scottish king when endangered by a stag.'

Although the chieftainship of the clan now descends regularly from father to son or other heir male, there can be little doubt that in antient times the custom of tanistry prevailed among the Scottish Highlanders, as it did down to a comparatively recent date among the Irish. [Brehon Laws, p. 383.]

The common prefix of the Scottish patronymics of clans, as every body knows, is *Mac*, that of the Irish *O'*—both signifying son, or at least descendant. But many Irish names also begin with Mac, and some with the synonymous Norman Fitz, the same word with the modern French *Fils* and the *vitz* or *witz* used as an affix in the same sense by the Russians. Several of the Scottish clans however have surnames in which the common prefix does not appear—as, for instance, the Stewarts, the Gordons, the Robertsons, the Camerons, the Campbells, the Chisholms. Several of these are generally understood not to be of Celtic descent. Indeed the tribes inhabiting the southern borders of Scotland, whose connexion with and dependence upon their chiefs used to be nearly the same with what prevailed in the Highlands (see the *Introduction to Scott's Minstrelsy of the Scottish Border)*, are often also familiarly spoken of as clans. Scott, in the battle canto of Marmion, says,

'Against them come,
Of gallant Gordons many a one,
And many a stubborn Badenoch man,
And many a rugged Border clan,
With Huntley and with Home.'

And the old Scottish statutes, passed in the sixteenth century for regulating the Borders, speak of 'clans having captains and chieftains, whom on they depend, oft-times against the wills of their landlords.' 'Of course,' says Scott, referring to acts passed in 1574 and 1587, 'these laws looked less to the feudal superior than to the chieftain of the name, for the restraint of the disorderly tribes; and it is repeatedly enacted, that the head of the clan should be first called upon to deliver those of his sept who should commit any trespass, and that on his failure to do so he should be liable to the injured party in full redress.' (*Introduction to Border Minstrelsy.*)

According to Colonel Stewart (*Sketches*, &c., vol. i.), the Gaelic clans of Scotland occupy the counties of Sutherland, Caithness, Ross, Inverness, Cromarty, Nairn, Argyle, Bute, and the Hebrides, with part of Moray, Banff, Stirling, Perth, Dumbarton, Aberdeen, and Angus. He has given a map of Scotland, in which the locality of each clan is marked; and in the second and third sections of his work he describes and examines the system of clanship and its consequences. In his second volume, Appendix Q is on the Distinctive Patronymics of the Clans. In Robert Patten's 'History of the Rebellion of 1715' (3rd edit. 8vo. Lond. 1745), pp. 191—199, is given 'A List of the most considerable Chiefs in Scotland, and the number of men they can raise, with an account of their disposition for or against the government,' which includes the clans. 'Note,' says Patten, 'that all the chiefs in Scotland are chiefs of clans, properly so speaking, whether noblemen or gentlemen; but commonly the last only are called the clans, and particularly those of them who live in the north and west Highlands and Isles.' Patten's list may be compared with a 'Memorial on the Military Strength of the Clans,' which Colonel Stewart has printed in his Appendix C, and which he conceives to have been drawn up a short time before the rebellion of 1745 by President Forbes. Bishop Nicolson has printed in his 'Scottish Historical Library' from Bell's MS. 'Introduction to the History of Cumberland,' a catalogue of the chiefs and clans of what was called the west border of the south of Scotland, that in 1547 submitted and gave pledges to Lord Wharton, who had overrun the country, that they would serve the king of England, with the number of followers they could command annexed to the name of each. It has been transferred by Scott to a note on his 'Introduction to the Border Minstrelsy,' along with a list of the east border chiefs who did homage the same year to the duke of Somerset, from William Patten's Diary of the duke's expedition, originally printed in 1548, and reprinted in Dalyell's 'Fragments of Scottish History.'

In Chambers's 'Popular Rhymes of Scotland' (12mo. Edinb. 1826, pp. 246—256) may be found a collection, which the writer, however, admits to be very meagre and defective, of the slogans, or war-cries, of various clans both of the Highlands and the Borders. On this subject see also Colonel Stewart's Appendix D. In Mr. Chambers's curious volume (pp. 197—246) are collected and illustrated the characteristic epithets proverbially applied to many of the clans and other Scottish families; such as the Gay Gordons, the Greedy Campbells, the Dirty Dalrymples, the Gallant Grahams, the Light Lindsays, the Manly Morisons, the Haughty Hamiltons, the Sturdy Armstrongs, the Saucy Scots, the Gentle Johnsons, the Lucky Duffs, the Setons Tall and Proud, the Wild Macraws, the Handsome Hays, the Trusty Boyds, the Muckle-mow'd Murrays, &c.

No complete history of the Scottish Clans, as far as we are aware, has been compiled. But there are several histories of particular clans, both printed and manuscript. The second part of William Buchanan of Auchmar's 'History of the Antient Surname of Buchanan' (12mo., Glasgow, 1793) consists of a 'Brief Enquiry into the Genealogy and Present State of Ancient Scottish Surnames,' and contains the legendary or traditional history of most of the principal clans. There is also a work entitled 'Antiquity of the Macs, Clans, and Bodotria,' by the Reverend John Lane Buchanan, A.M., missionary minister to the Isles from the church of Scotland, of which we have not been able to find a copy. In a newly established periodical publication, entitled 'Transactions of the Iona Club,' 8vo., Edinb., 1834, &c., consisting of 'Collectanea de Rebus Albanicis,' there is printed (vol. i., pp. 50—63), with a translation and notes, a Gaelic account of the genealogies of the Highland clans, from a MS. which appears to have been written about the year 1440. In his concluding note the editor observes, 'It would occupy too much space here to enter into any detail of the very important effects which this MS. must produce upon the question of the origin of the Highland clans; it will be sufficient to state that it seems to establish three very remarkable facts:—1. The existence at a very early period of a tradition in the Highlands of the common origin of all the Highland clans;—2. The comparatively late invention of many of the traditionary origins of the different clans at present believed;—and 3. The natural relationship of various clans which have hitherto been supposed to be altogether unconnected.'

The system of clanship as it still subsists in the Highlands of Scotland, making allowance for the modifications it has received from the feudalism, in respect to the tenure of property superinduced upon its original purely patriarchal character, is essentially the same state of society that has always prevailed among the wandering Arabs and Tartars of the East. Gibbon's description of the social condition of the Tartars, or, as he calls them, Scythian hordes, in his 26th chapter, would, in great part, suit the state of things in the Highlands, at least as it remained down to the rebellion of 1745. Since that attempt, and the measures which the government was induced to take in consequence of it, the old spirit of clanship has considerably declined.

CLAPPERTON, HUGH, was born in 1788, at Annan, in Dumfriesshire, N.B., where his father was settled as a surgeon and country practitioner. After receiving the rudiments of a plain education, with some instruction in mathematics, he went to sea at the age of thirteen, being bound apprentice in a merchant-ship that sailed between Liverpool and America. After making several voyages he was impressed and sent on board a man-of-war as a common seaman. Fortunately Clapperton had an uncle, a captain of marines, through whose interest with the naval commanders then in commission in the Mediterranean, he was put on the quarter-deck and made a midshipman. In this capacity he gave splendid proofs both of fortitude and courage. In 1814 he went to Upper Canada, and some time after his arrival he was promoted to the rank of lieutenant, and appointed to the command of a schooner belonging to the British flotilla on the lakes. In 1817, this flotilla having been dismantled, Lieutenant Clapperton returned home on half-pay. He amused himself in his native district with shooting and fishing, until 1820, when he removed to Edinburgh and became acquainted with the late Dr. Oudney, whose mind was absorbed by the subject of African discovery. In 1823 he was employed by Lord Bathurst, in conjunction with Dr. Oudney and the late Major Denham, to make a journey to Timbuctoo, in central Africa. The doctor died at an early stage of the journey in January, 1824. Proceeding south from Tripoli, on the Mediterranean, by Musfeia, and by Zangalia, on the east of the great lake Tchad, Clapperton, after great sufferings, reached Saccatoo, where he was obliged to turn back. He and Denham determined the positions of the kingdoms of Mandara, Bournou, and Houssa, and of their chief towns, but they were not able to ascertain the course and termination of the Niger—the main object of the expedition. From their experience they gave rather a favourable notion of the civilization and hospitality of some of the nations in the interior of Africa, who had been previously set down as ferocious savages. Their description of lake Tchad, with the huge hippopotami in it, and the elephants and other wild animals on its shores, is exceedingly interesting. On the 22d June, 1825, soon after his return to England, Clapperton was raised to the rank of commander, and engaged almost immediately to start afresh on the same perilous journey. His companions were Captain Pearce, R.N., Mr. Dickson, and Dr. Morrison, a navy surgeon and naturalist; the party was attended by Richard Lander, Dawson, and two or three other servants. This time Clapperton penetrated into Africa from the coast of the Atlantic. The party landed in the Bight of Benin on the 28th of November, 1825, and proceeded inland from Badagry, December 7; but they had scarcely moved from the shore when they were attacked by the usual maladies of the country. Dawson died at Tshow, not far from Badagry, and Captain Pearce soon after, at Engwâ. Dr. Morrison, who had returned towards the coast, expired at Jannah. The survivors, meeting with great kindness and hospitality from the natives, reached Katunga, the capital of Yariba, on the 15th of January, 1826. They proceeded to the great commercial city of Kano, and thence, bearing to the west, went to Saccatoo, which Clapperton had reached from the side of the Mediterranean on his former journey. [AFRICA.] Here Bello, the king or chief of the country, detained his old acquaintance on account of wars carrying on, and (it is said) at the jealous suggestions of the Dey of Tripoli, who represented the English as aiming at the possession of all Africa. Clapperton's vigorous constitution gave way under the effects of the climate and privation, and he died of dysentery on the 13th of April, 1827, at Chungary, a village four miles from Saccatoo.

(*Narrative of Travels and Discoveries in Northern and Central Africa in the years* 1822, 1823, 1824, by Major Denham, Commander Clapperton, and the late Dr. Oudney, 4to., Lond., 1826.—*Journal of a Second Expedition into the Interior of Africa*, &c., by the late Commander Clapperton. 4to., Lond. 1829. To this volume a Memoir of his Life is prefixed.—*Records of Captain Clapperton's Last Expedition to Africa*, by Richard Lander, his faithful servant, and only surviving member of the Expedition. 2 vols., small 8vo., Lond. 1830.)

CLARE, a maritime county of the province of Munster, in Ireland: bounded on the north by the county of Galway; on the east and south by the Shannon, which separates it from the counties of Tipperary, Limerick, and Kerry; and on the west by the Atlantic Ocean. The greatest length, from Loop Head on the south-west to the Galway boundary on the north-east, is 67½ miles; greatest breadth, from Black Head on the north-west to Bunratty on the south-east, is 38½ miles. The area is estimated by Beaufort at 1195 English square miles, or 765,042 statute acres.* Gross population, in 1821, 208,089; do. in 1831, 258,322.

The surface of this county is extremely irregular. The high lands occupy about 150 square miles, included between the Shannon on the east and the Galway boundary on the north. Here the Slieve Baughta mountains attain an elevation of from 2000 to 2500 feet. This group stretches into the adjoining county, and contains three principal connected lakes: Loch Teroig, on the boundary of Clare and Galway; Loch Graney, farther south in the centre of the group; and Loch O'Grady, between Loch Graney and that expansion of the Shannon called Loch Derg in the east, into which the waters of the district discharge themselves by the Scariff river at the village and creek of the same name. Southward from the Slieve Baughta group extends a mountainous tract of less elevation, which runs with little interruption from Scariff on the north to Bunratty on the south, where the waters of Loch Breedy, Loch Doon, Loch Cloonlea, and several other lakes, lying along the western border of the range, discharge themselves by the Ougarnee river into the Shannon. The chief drain of the eastern part of this district is the Blackwater, which falls into the Shannon a little above Limerick. West of these groups, and occupying the central district of Clare, there is a comparatively level country stretching north and south, the waters of which, collected from Lochs Inchiquin, Tedane, Inchicronane, Dromore, Ballyally, and several others, unite about the centre of the county and form the Fergus, a fine navigable river, which, augmented by the Clareen at Ennis, the county town, flows due south by Clare, and, after forming a large æstuary with numerous islands and excellent anchorages, unites with the Shannon about eight miles west of Bunratty. The junction of these rivers forms a very noble expanse of water. The remainder of the county, from Loch Buneah in the north to Clanderalangh in the south, and thence westward to the ocean, is occupied by high lands, the waters from which flow chiefly into the Atlantic by the Dunbeg and Ennistymond rivers. Of these heights the principal is Callan mountain, rising westward from Ennis, over Milltown, a small but flourishing coast town situated about midway on the western line of sea coast. Clare has a much greater extent of coast line than any other county in Ireland. From Scariff, on the Shannon, to Curranrue, on Galway bay, the whole length of coast line is 230 English miles, of which about 140 lie along the Shannon, and 80 on the coast of the Atlantic. This coast, from Black Head on the north to Loop Head on the south, a direct line of nearly 60 English miles, has only two harbours, and these not capable of sheltering vessels of more than 50 to 100 tons. With the exception of the small bays or fishing stations of Kilkea, Dunbeg, Milltown and Liscanor, the whole coast is iron-bound. The Reverend James Kenny, in his statistical account of the union of Kilmanaheen, states that the cliff on which the signal tower of Moher is erected was found by measurement to be 909 feet high, and that the rock somewhat to the eastward proved upon the same measurement to be 1009 feet high. The cliffs average 100 feet in height, and in some places, as at Baltard and Moher, present a face of rock of 500, and even, it is said, of 1000 feet, against which, during a gale, the waves of the Atlantic beat with astonishing fury. Numerous islands and detached stacks of rock mark the devastating effects of these storms, which have disconnected them from the main land. During a storm from the Atlantic the waves have been driven from the bay to the top of the cliff at Kilkea, a height of more than 100 feet, and, rushing down the green fields which back the precipice, have fallen into the little river at the inland foot of the hill. (*Two Months at Kilkea, &c.* Dublin, 1836.)* Where there is a beach, as at Moore Bay and Dunbeg, the swell causes a constant surf. As boats built in the usual manner could not live in such a sea, the people of the coast employ a sort of canoe, formed of tarred canvass spread on a wicker frame, called a *corragh*, similar to the rude vessel used by the antient Britons. In these they frequently go 50 or 100 miles out to sea, and venture with little danger among rocks and shoals where any vessel less pliable would go to pieces. A rent in the canvass is repaired by drying the edges and applying a fresh piece of cloth, spread with hot pitch, to the outside. From the dangerous character of the coast some derive the appellation of Malbay, by which the indentation extending from Dunbeg to Liscanor is known.

---

* This estimate is uncertain until the completion of the Ordnance Survey of Ireland.

The shore of the Shannon, commencing from Loop Head, has numerous creeks, which might be rendered useful either as asylum harbours or stations of trade; but at present there is no security for vessels of heavy tonnage in hard weather nearer to Loop Head than the anchorages of the Fergus. At Carrigaholt, a small village immediately under Loop, is a fishing pier, and at Kilrush, a very prosperous place, about half way between Carrigaholt and the Fergus, is a pier with a quay on a good scale, and every facility for the construction of an excellent harbour; but, until the pier is carried farther forward towards a neighbouring island, so as to screen shipping from the southerly winds, the roadstead cannot be counted secure. 'I will here observe,' says Captain Mudge, in his report (1831-2), 'that this part of the Shanon is exposed to the whole ocean swell; the sea, which sets in such a continuance of southerly or westerly winds, baffles all description, especially when accompanied by the "rollers," a periodical visitation: at such times the swell will break in 12 and 13 fathoms water, or wherever there may happen to be any foul ground.' Eastward from Kilrush the Shannon, which at its entrance is ten English miles in width, begins to contract; but after sweeping in a comparatively narrow and very deep channel round the peninsula of Clanderaulagh, between which and the shore of Limerick is the race of Tarbert, it expands again to a width of several miles at its confluence with the Fergus, about ten miles farther inland. The entrance of the Fergus lies between Innismurry island on the west, and Rinana point on the east. The æstuary is here five miles wide. Towards the western side it is encumbered by islands, of which there are eight considerable ones covering about four square miles. These islands are surrounded with weed and sandbanks, and contract the ship channel to a breadth of about three-quarters of a mile. The channel is safe for vessels drawing sixteen feet of water: and on the mud banks at either side a ship may at all times ground with safety. The tide here seldom runs more than 2½ miles per hour. In the channel there are good anchorages in from three to six fathoms water. The existing dangers and drawbacks are so trifling that a very small expenditure of money would render the Fergus, from its junction with the Shannon to the bridge of Clare, one of the safest and best navigations in Ireland. From the Shannon to Clare the river is called the Lower Fergus, and from Clare to Ennis the Upper Fergus. The Upper is a deep and quiet piece of water, more like a large canal than a river. It is separated from the Lower Fergus by a ledge of rock on which the butments of the bridge of Clare are built. This natural dam keeps the upper part of the river constantly full and navigable to Ennis, the county town, three miles distant. The least water in any part of the Upper Fergus during summer is 13 to 14 feet, and generally 18 to 25, and the average width of the river 150 feet. By connecting the navigations of these two natural canals, Ennis would be brought into an easy and cheap communication with Limerick, and the immense expense hitherto incurred by the farmers of Clare in transporting their goods overland to a market would be most materially reduced. It is affirmed that an outlay of 400*l.* to 500*l.* would give the merchants of Ennis the means of avoiding 12*s.* 6*d.* per ton carriage on grain which they now export from Limerick. So great was the expense of land carriage in this district, in 1830, that coals, burned in Limerick at 22*s.* per ton, cost in Ennis 35*s.*, while all the iron brought overland to this, the assize town of a large county, incurred the enormous charge of 8*d.* per hundred for carriage alone. The subject of the navigation of the Fergus has however been taken up with great spirit by many of the influential resident gentry, and a final report is now in course of being made on this branch as well as on all the other branches of the navigation of the Shannon by commissioners appointed by Government. Eight miles east from Rinana point is the Ougarnee, up which the tide flows to Six-mile Bridge, but the vicinity of Limerick renders its navigable capabilities of little importance. One suburb of Limerick lies in the county of Clare, as well as the chief lines of canal by which the navigation of the Shannon is continued from that city to Killaloe. The whole of the shore of Loch Derg from Killaloe to Scariff might be rendered available for stations of commerce; but the present trade on the Shannon, although latterly much increased, is not yet sufficiently extensive to bring these capabilities into use. It has been proposed to cut a canal from Scariff by Loch Graney through the valleys of the Slieve Baughta mountains and the flat country beyond to the bay of Galway, and also from Poolanisherry bay, near Kilrush, through the flat tract of bog that extends northward to Dunbeg on the Atlantic, so as to give access to the Shannon to vessels embayed in Malbay, without doubling the dangerous promontory of Loop Head; but no attempt has yet been made to carry either scheme into effect.

The roads of this county are perhaps worse than in any other county of Ireland, which is chiefly attributable to the corrupt system under which the grand jury assessments were formerly applied. The evils of this system are now removed by the appointment of a county surveyor, who superintends the application of the public money, and without whose sanction no presentment can be levied. Considerable sums have latterly been advanced by the Com-

---

[*] 'Some faint idea may be formed of the force with which the waves of the sea are impelled by western storms, when it is known that cubes of limestone rock, 10 or 12 feet in diameter, are thrown upon ledges of rock several feet high near Doolen; and at the same place may be seen a barrier of water-worn stones, some of them many tons in weight, thrown up above 20 feet high across a small bay, into which fishermen used to land from their boats, and where their former quay, surrounded with huts, remains many yards from the sea: this has occurred within the memory of many living at present.' (Dutton's *Survey of Clare.* Dublin, 1808.)

missioners of Public Works for the construction of roads and bridges in this county; the sums advanced being repaid by instalments presented by the Grand Jury.

The climate is remarkably healthy. Instances of longevity are very frequent. In 1824 there were in the single barony of Bunratty eight individuals, four males and four females, each upwards of 100 years of age. The county is in general much exposed, particularly to violent gales from the Atlantic. Frost and snow seldom continue long. In the sheltered portions of the eastern district, the climate is moist and very mild. Myrtles, both broad and narrow-leafed, have been known to attain a height of upwards of eighteen feet in the open air at Bunratty.

With regard to the geology of Clare, no map exhibiting more than the limits of the limestone district has yet appeared. The Slieve Baughta mountains consist of a nucleus of clay-slate, supporting flanks of sandstone, intruded through a break in the surrounding limestone plain, in the same manner as the Slieve Bloom range on the opposite bank of the Shannon. The limestone, which insulates this mountainous district, spreads westward over the more level basin of the Fergus, and rises into very rugged elevations towards the Galway boundary on the north-west. Beyond the basin of the Fergus commences an extensive clay-slate and trap formation, which stretches westward from the limestone field to the waters of the Atlantic, to which it presents those precipitous escarpments of the coast-line. The whole of this coast abounds in phenomena of the greatest interest, but hitherto they have not been described.

Beds of ironstone and several strata of coal occur upon Mount Callan; a seam of coal, three feet thick, appears in the face of the rock a little above high-water mark over Liscanor Bay, near Ennistymond; and again, near Mutton Island, both inland and on the shore of Malbay; another seam appears in the bed of a river near Carrigaholt, as also at Fieragh Bay, Lemaduff, and Longhill Ferry. Iron ore is found at several places, and in considerable quantities on the Malbay coast, on the banks of the Ardsallas, a feeder of the Fergus flowing from the east, on the shore of Liscanor Bay adjacent to the coal tract, between Corrofin and Ennis in the centre of the county, and in several other places. Rich lead ore abounds in the limestone district, particularly in the mountainous parts of the barony of Birren in the north of the county. Copper pyrites is plentiful in the same barony. Manganese is found at Ennistymond, Carrigaholt, Cross, and other places on the sea-coast. Chalybeate waters abound in the district westward from the sources of the Fergus. Very fine black marble has been raised at Craggliath, near Ennis; it takes a high polish, and is free from spots. On the shore of Loch Graney is found a hard crystalline sand, much used for scythe boards, which are greatly superior to those brought from England. The coast from Kilrush to Carrigaholt abounds with excellent slate and flag quarries. There are also quarries of flag of a good quality at Ennistymond. The Broadford slates from this county have long been celebrated, and are considered nearly equal to the best Welsh; an inferior article is obtained from the slate quarries at Killaloe.

The characters of the different soils correspond to the characteristic geological division. In the schistose and trachyte districts the soil is cold and moory; in the calcareous region warm and friable, though light; on the borders of the different tracts, especially of the slaty and calcareous, deep and loamy. The extent of poor soil is much greater than that of even middling quality; but in some districts there are detached spots of very remarkable richness. These are usually situated along the banks of the large rivers, and are liable to periodical inundations. They are called corcaghs or corcasses, a word nearly synonymous with the English provincial term bottoms. Six tons of prime hay are frequently produced from the Irish acre on these rich levels, and eight tons per acre have been occasionally mowed. The substratum is either a black or a blue alluvial clay, resting on limestone gravel: the black corcass is preferred for tillage, as being drier; the blue for meadow and pasture. They lie chiefly along the Shannon and Fergus from Limerick westward, in some places extending inland to a considerable distance. They are computed at about 20,000 acres in all. One tract of uncommon richness, called Tradree, or the King's Land, is said to have been the private patrimony of the famous Brian Boroimh The rent of corcasses varies from 3 to 7½ guineas per Irish acre. Another species of rich grazing land of frequent occurrence here as well as in Galway, is the turlogh, or periodical lake, an accumulation of water either forced upward by subterranean channels, or formed by surface-waters which have no outlet. These floods lie in the turlogh during the winter, and leave it prepared for the most abundant vegetation in the spring. In one of these turloghs, 48 Irish acres in extent, near Kilfenora, on the north-western boundary of the limestone district, the proprietor has fattened in one year 42 large oxen and 44 sheep, besides grazing 17 horses and a number of swine; and in the following year has sold off it, in fine condition, 100 two-year old bullocks, and 16 or 17 horses. The whole of this calcareous tract abounds with subterraneous communications through which the water passes from lake to lake, as at the sources of the Fergus, or rises to the surface and forms temporary pools and turloghs. The barony of Burrin, which comprises the north-western portion of the limestone field of Clare, is perhaps the most remarkable district in Ireland. Here the bare limestone rock rises to the surface in all directions, so as to give the whole district the appearance of being covered with a white cement. The country is everywhere very rugged and hilly, and the worst supplied with water of any in Ireland. In an area of twenty English miles by ten, there is but one stream running to the sea, and that has a course of barely eight miles. Another rivulet near it disappears under the crust of limestone after a course of three miles. The only supply of water in the interior is by turloghs. One of these at Kilcorney, a place remote from any river, is fed by a periodical stream issuing each winter from a cave in the vicinity. In the last century this curious cave attracted the attention of Dr. Lucas, who has given an interesting account of it in the 'Philosophical Transactions' for January, 1740, No. 456, p. 360. Notwithstanding its sterile appearance, this county is far from being unproductive. In the crevices of the limestone rock sprouts a very sweet and nutritious grass, particularly well suited for fattening sheep. Yarrow, white clover, trefoil, cinquefoil, virga aurea, juniper, and yew, grow spontaneously and in abundance, although in patches. Some portions of the grazing land set for 3*l.* per Irish acre; and on a few farms store bullocks are fattened for the Limerick and Cork markets. In general however the land is set for very low rents, and by the bulk; and is almost solely devoted to the grazing of sheep, as this stock does not require a copious supply of water like black cattle. The prime sheep-walks here are estimated at above 10,000 acres: some of the rocky pastures are however so poor that it is said four acres will not feed a sheep. The supply of fuel is equally scanty, there being little or no bog; yet from the numerous remains of castles in all parts of the barony, it is evident that it must have been thickly inhabited during its possession by the old Irish. The present inhabitants of the coast procure their supply of turf in boats from the opposite shores of Galway. In all other parts of the county there is abundance of fuel, particularly towards the south-west, where a tract of bog, containing 14,950 Irish, or about 24,000 English acres, extends from the Shannon at Kilrush to the shores of the Atlantic at Moore Bay and Dunbeg. Large quantities of turf are annually exported from the Kilrush side to Limerick. This is the tract through which it was proposed to cut a canal. It is estimated to be reclaimable at an expense of 31,728*l.* There is no limestone in this part of the county, but an inexhaustible supply of sea-sand can be had at Dunbeg. Notwithstanding these inducements to reclaim the portion of this great tract not necessary for purposes of turbary, it still remains an unprofitable waste. The bog of Douragh, eastward from the Fergus, affords the principal supply of turbary to Ennis and Clare. The turf is ricked on the banks of the Upper Fergus, and thence boated to market. Although the county is at present very bare of trees, the bogs abound in timber. A fir-tree measuring 38 to 39 inches in diameter by 68 feet in length was some time since raised from a bog near Kilrush; and it had lost much of its original bulk by decay. The mode of finding bog-timber as practised here is rather remarkable. It is found that the dew does not lie on the part of the bog immediately above a tree, as it does elsewhere. The position of a piece of timber can thus be easily ascertained before the dews rise in the morning; when the finder, after probing with a bog-auger, called in Irish tharagher, to ascertain whether the wood be sound, marks the spot with a spade, and proceeds to raise the timber at his leisure. Fir, oak, and yew, are the chief sorts of bog-wood found.

Agriculture, although rapidly improving, is still in a backward state. Green crops and artificial grasses have been only lately introduced to any considerable extent. The breed of sheep remains in many districts unimproved, from a prejudice against the mutton of the finer-woolled kinds. The general breed of swine is very inferior. The custom of fattening choice heifers for slaughtering has prevented the attention that ought to have been paid to providing superior breeders. The improved breed is however extending; and to meet with stock of the old Irish kind is now unusual. Bulls have been imported by many of the resident gentry from Leicester, Warwickshire, and other grazing districts in England; and the black cattle now sent to market from their prime grazing-lands are of a very improving breed. In the grazing districts along the western coast it is usual to stall the cattle during the greater part of the winter months, as the pasture is completely withered by the violence of the sea-storms that beat on these exposed uplands; but this expedient is very different from any regular system of stall-feeding. The bad state of the roads still renders the employment of asses and panniers not unusual, and in general the small farmers' horses are badly fed and worse appointed.

There is an excellent opening for the establishment of fisheries along the whole of the coast from Kilrush to the bay of Galway. Salmon are taken in great quantities at the mouth of the Shragh or Dunbeg river. The banks of Baltard afford excellent turbot, cod, haddock, ling, dory, mackerel, whiting, and pollock, in great abundance. In the mouth of the Shannon is a regular station for the herring fishery. The oyster-beds of Burrin are celebrated in the Dublin market. Crabs, lobsters, and shrimps are caught in all the creeks; and the cliffs along the whole western coast abound with samphire, dilisk, sloak, and Carrigeen moss. Vast quantities of sea-weed, which forms the best manure for the slaty soil adjacent, are thrown up by every tide on the different beaches and creeks.

There are no manufactures, except of home-made frieze for the use of the peasantry; and the commerce consists chiefly in the export of provisions. Grain and pigs are the articles usually shipped from Carrigaholt, Kilrush, and Clare, which are the only exporting towns in the county.

The exports of the county at large, in the year 1831, as estimated by Captain Mudge, are as follows:—

Wheat	24,000 barrels, or	3000 tons.
Oats	96,000 „	8000 „
Barley	10,000 „	2000 „
Beans	„ „	300 „

Butter, bacon, and cattle, not known.

Large quantities of grain are sent over land to Limerick; pigs also are driven over land in great numbers.

Imports for 1831.

	Tons.	
Timber	1000	
Iron	500	
Salt	500	
Coals	2500	
Slate	500	
Flags	500	
Bricks	1000	
Whisky	500	
Earthenware	500	(by measurement)
Glass	100	
Sugar	300	
Tobacco	200	
Mercantile goods and sundries	1500	(by measurement)

and about 200 tons per month of turf, brought to market in boats by the Fergus.

There are branches of the provincial and agricultural and commercial banks at Ennis, and a branch of the latter, and of the Limerick national bank, at Kilrush.

Clare is divided into nine baronies: Tullagh and Bunratty on the east; Inchiquin and Islands in the Centre, the latter so called from the islands of the Fergus embraced by it; Burrin; Corcrmore, Ibrickan, and Moyferta, extending along the western coast from Black Head on the north to Loop on the south, and Clanderlaw east of Moyferta, between it and the barony of Islands. The county contains the entire diocese of Kilfenora, the greater portion of the diocese of Killaloe, and a small portion of the diocese of Limerick. It contains 74 parishes, forming 28 benefices. The only corporate town is Ennis, which formerly returned two members to the Irish, and now returns one member to the imperial parliament. Kilrush is the place of next importance. Corrofin (population 900), Ennistymond (population 1430), Six-mile-bridge (population 1491), and Killaloe (population 1411), are inconsiderable places. The county returns two members to the imperial parliament. The newspapers which circulate in Clare are chiefly printed in Limerick. The number of stamps issued to the Clare Journal for the year ending January, 1836, was 11,484.

The assizes for the county are held twice a year at Ennis, where is a new and good county gaol. There are also bridewells at Ennistymond, Kilrush, Six-mile-bridge, and Tulla. The district lunatic asylum at Limerick comprises this county, which pays a quota of the annual expense proportioned to the number of patients sent from it. For the year 1835 the expense was 1034*l.* 2*s.* 7*d.*, the number of patients being 63. The proportion of the original cost of building the asylum paid by the county was 8955*l.* 8*s.* 1*d.*, the gross cost being 30,200*l.* 17*s.* 2*d.* Of the constabulary and peace-preservation forces, 417 are employed in Clare, at a total expense of 15,987*l.* 9*s.* 4*d.* for the year 1835. Of the expense of maintaining the constabulary department, 5479*l.* 2*s.* 3*d.* is chargeable against the county.

The civil history of the county of Clare abounds with nterest, but we can only glance at the chief events. Originally it formed part of Connaught, but in the year 298, Lugad or Lewy, surnamed Meann, one of the Dal-Cassian successors to the monarchy of Leath Mogh, finally settled the bounds of his kingdom to the limits fixed between Owen More and Conn, about the close of the second century, and thus included it in Munster. The territory corresponding with the present county of Clare, together with the original patrimony of the tribe of Cas, east of the Shannon, was then called Tuaidh Muin or Thomond, that is, North Munster, a name which afterwards distinguished it from Jar Muin, or Ormond, and Des Muin or Desmond, two other divisions of Munster to the east and south. This antient Thomond comprehended the present counties of Clare, Tipperary, and Limerick nearly,[*] and was ever after accounted the especial patrimony of the tribe of Cas, who are distinguished in Irish history as the Dal-gais, in opposition to the descendants of Oeven, who are known as the Esganacht of Cashel.

Before the year 1168, antient Thomond had been di vided into modern Thomond on the west, and Ormond on the east; and of this latter portion his younger brother Brian, surnamed 'of the Mountain,' was king at the accession of Donnell the Great. Donnell, on his accession, inhumanly put out his brother's eyes, and had himself proclaimed king of all North Munster. He married the daughter of Dermot Mac Murrogh, king of Leinster, the inviter of the adventurers under Strongbow; and being also at war with Roderick O'Connor, king of Connaught, an hereditary enemy, he readily availed himself of the proffered assistance of Robert Fitz-Stephen, when sent as an ally by his father-in-law Dermot. By this means the English gained their first footing in Munster, A.D. 1171. Next year, to secure so effectual an assistance against his great enemy, Donnell did homage to Henry the Second soon after his landing at Waterford, upon which an English garrison was planted in Limerick; but the year after, repenting of his allegiance on some provocation received from his new allies, he assailed the castle of Kilkenny, which he destroyed, and defeated the English of that part of the country in several engagements.

---

[*] The boundaries of antient Thomond, as determined by the treaty of Dioma, were, from Slighe Dala in Ossory on the east to the Atlantic on the west, and from the isles of Arran on the north to Cashel, Knockaine, and the river Feal on the south.

In the year 1543 Morrogh O'Brien, after a fruitless attempt at raising a general rebellion with O'Neill, O'Donnell, and O'Connor, came in and made his allegiance to King Henry the Eighth, renouncing the name of O'Brien, and taking the title of Earl of Thomond, with the style of Baron of Inchiquin for his eldest son. At the same time he surrendered all his possessions to the king, and received them back by an English tenure, as also did O'Neill and Mac William Burke, who were at the same time, and on similar terms, created earls of Tyrone and Clanrickard. By the articles of this submission, the earl agreed to abjure the Irish language, to bring up his people in the practice of husbandry and tillage, and to pay none but legal rents, &c. From him descended in a direct line the family of Inchiquin, several of whom were distinguished leaders in the subsequent wars, particularly Murrogh, the first earl and fifth baron Inchiquin, a celebrated parliamentary and royalist general in the wars from 1641 to the Restoration. Soon after the first earl's submission, Thomond was made shire-ground. An act for the division of Connaught into counties having passed (11 Eliz., c. 9), Sir Henry Sidney (others say Thomas earl of Sussex) plotted out six counties beyond the Shannon, of which Clare was one. Its first division was into eight baronies, different both in names and boundaries from the present. They were laid down in accordance with the possessions of the then principal families, namely, the Macnamaras and O'Gradys on the east, the O'Loughlins on the north, the Mahons and Mac Mahons and O'Deas on the west and south, and the O'Briens of the earl's immediate connexion in the central baronies. One hundred and seventy-two castles are enumerated in this early survey, of which twenty belonged to different gentlemen of the family of O'Loughlin, in the barony of Burrin or Gragans alone. Upon the petition of the second earl of Thomond, 1601, the county of Clare was again made part of the province of Munster, although for convenience sake it continued on the Connaught circuit until the latter end of the last century. The adhesion of Lord Inchiquin, the most influential person in Clare, to the British interest during the wars from 1641 to the Restoration, prevented this part of the county from being the scene of any military operations of importance. Such as did occur were in connexion with the history of Limerick. Pursuant to an ordinance made for the satisfaction of adventurers and soldiers, by the English parliament, in 1653, a district was laid out along the sea-coast of all Connaught, including this county, called the *mile-line*, from its being in breadth nowhere less than four miles from the sea, beyond which in the interior the dispossessed Irish were to be located, and in which, as a barrier between the insulated Irish and the sea, the adventurers and others were to have their portions. This plan of wholesale transplantation was never fully carried into effect. The property of the county cannot be looked on as at all settled until after the Revolution of 1688, when the disposal of the new forfeitures, amounting to 72,246 profitable acres, Irish measure, valued at 12,060*l.* 17*s.* per annum, introduced a new and permanent proprietary. This great tract of country was principally the estate of Daniel Lord Clare, of Carrigaholt, who had raised a regiment of dragoons, and fought in the service of James the Second from the commencement of the war till after the battle of Aughrim. He was grandson of Sir Daniel O'Brien, who had forfeited the same estates in 1641, and had afterwards been restored and created baron of Mogarta and Viscount Clare by Charles the Second in 1662. The other principal forfeiters, in 1688, were Donogh Mac Namara, Donogh and Tiege O'Brien, and Redmond Magrath. The rebellion of 1798 scarcely extended to this county. During the present century Clare was for a time remarkable for agrarian disturbances, now happily at an end. The Clare election of 1828, in which a Roman Catholic was returned to the imperial parliament previous to the removal of the disabilities affecting that part of the population, will form an important epoch in Irish history.

Antiquities.—There are round towers at Scattery Island, off Kilrush (120 feet high, a known landmark in the navigation of the Shannon), at Drumcliff in the barony of Islands, at Dysert (the antient Dysert S'Dea) and Kilnaboy in the barony of Inchiquin, and at Innis Cailtre, an island in the creek of Scariff, on Loch Derg. The abbey of Ennis, which the famous Tenlogh O'Brien enriched in 1306 with bells, crosses, rich embroidery, and painted glass windows (*Annals of Innisfallen and Caithercim Foirdelbach*), is still standing. The abbey of Quin, in the barony of Bunratty, about five miles east of Ennis, is a noble pile of black marble, for the building of which, in the thirteenth century, Comea More Macnamara, the founder, is said to have been created a prince by the pope. Bishop Pococke describes it as 'the finest and most entire monastery in Ireland.' The ruins on the islands of Innis Scattery and Innis Cailtre are also of great interest to the antiquary. Cromlechs are numerous, and the tomb of Conan on Mount Callan, with its Ogham inscription, is still the subject of inquiry and dispute. There are still standing 118 castles, and raths in all directions. The original documents by which different contracts were made here under the Brehon law are extant, particularly the rentals of Macnamara and O'Brien. Numerous Irish MSS. relating to this county are in existence, still untranslated. There is no portion of Ireland so well calculated to afford materials for a county history; yet the only work hitherto published on the subject is the meagre 'Statistical Survey,' by the agent of the Royal Dublin Society.

The character of the people is like that of the Irish peasantry in other counties, with this unfortunate distinction, that almost all authorities concur in representing the peasantry of Clare as addicted to giving untrue testimony in courts of justice.

Education.—The dioceses in which this county is comprehended stand only 24th and 25th among the 32 dioceses of Ireland. The number of schools in 1820 was 215; in 1821 there were 8159 males and 3794 females under instruction. As the returns of the Commissioners of Public Instruction for 1834 have reference to ecclesiastical divisions, see KILLFENORA and KILLALOE, within which dioceses Clare is comprehended.

The county expenses are levied by grand jury assessments. The annual amount levied averages, on a return of twenty years to 1829, about 28,000*l.* The mode of applotment is liable to many objections, which the Ordnance Survey now in progress is expected to remove. A map of the county, on a scale of one inch and a fourth to an Irish mile, was executed in 1787 by Mr. Henry Pelham: it is not accurate.

(*Statistical Survey of the County of Clare; Parochial Survey of Ireland;* Beaufort's *Memoir of a Map of Ireland;* Cox's *History of Ireland;* Vallancey's *Collectanea;* Inglis's *Ireland in* 1834; *Reports of the Record Commission for Ireland; Parliamentary Reports and Papers; MSS. in British Museum and in Library of Royal Irish Academy; Original Communications.*)

CLARE ISLAND, six miles in length, by two and a half in breadth, lies off the coast of the county of Mayo in Ireland. It is situated about midway between Achill island on the north, and barony of Morisk on the south, and in the offing of Clew Bay, which it partially shelters from the swell of the Atlantic. The island rises to the height of 2400 feet towards the west, where its shores are very precipitous. It is included in the parish of Kilgever and barony of Morisk, and in 1821 contained 257 houses and 1395 inhabitants. In 1831 the numbers were—houses, 303; inhabitants, 1616. In 1834 there were on the island two schools in connexion with the Board of National Education, educating from 80 to 120 young persons. This island has been beautifully modelled, on a scale of four inches to the mile, by Mr. Bald. The model is in the possession of the Royal Dublin Society. (*Reports &c.*, Bald's *Map of Mayo.*)

CLARE, ST., NUNS OF THE ORDER OF, otherwise called Poor Clares. The Nuns of the Order of St. Clare were instituted by that person at Assisi, in Italy, according to Newcourt, about A. D. 1212. This Order was confirmed by Pope Innocent III., and, after him, by Pope Honorius III., A. D. 1223, and was subsequently divided into a stricter and a looser sort. (Newc. *Repert. Ecclesiast.*, vol. i. p. 562.) 'St. Clare,' says Tanner, 'was born in the same town and lived at the same time with St. Francis, and her nuns observing St. Francis's rule, and wearing the same coloured habit with the Franciscan Friars, were often called Minoresses, and their house without Aldgate (London), the Minories.' They were probably called Poor Clares from their scanty endowments. They were brought into England by Blanch, queen of Navarre, who was wife to Edmund earl of Lancaster, Leicester, and Derby, under a licence from King Edward I., A. D. 1293, and were seated in the house already mentioned, without Aldgate. Besides this, there were only three other houses of this order in England, viz., Waterbeche and Denny in Cambridgeshire, and Brusyard in Suffolk. The total of the clear revenues of this order in England, at the suppression of religious houses, amounted to no more than 548*l.* 10*s.* 6*d.* (*Monasticon Anglic.* new edit., vol. vi., p. 1549; Tanner's *Notit. Monast.* Pref. p. 12—56; Dr. Fly's *Account of the Abbey called the Minories, Archæolog.* vol. xv. p. 92—113.)

CLARENCEUX, the name of one of the provincial kings-at-arms in the Heralds' College. It is uncertain when this office was first created. Anstis and Edmondson think it probable that it was by Edward III., but Noble thinks it was by Henry V., who, preferring the herald of his brother Thomas, Duke of Clarence, constable of the army, created him a King of Arms, by the title of Clarenceux, and placed the south part of England under his care. William Horseley was so created by Henry V., and Roger Lygh by Henry VI. Afterwards it sunk into the office of a herald only, but was again revived in the reign of Edward IV. in favour of William Hawkeslow, who had however the west of England only allotted to him as a province. Sir Thomas Holme, knight, who succeeded to the office in 1476, appears to have had first the west, and then the south of England, as the district in which he was to give armorial bearings.

The Arms of Clarenceux are, Argent, St. George's Cross, upon a chief gules a lion of England crowned with an open crown. The Badge is the same, in an escocheon, crowned with a crown of a king of arms, upon a green ground on one side; and on the other, the royal arms crowned upon a white ground, pendent to a gold chain, or simple riband.

(Noble's *History of the College of Arms*, 4to., London, 1804, p. 61 et seq.)

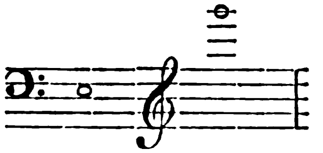
CLARENDON, LORD. [HYDE.]

CLARENDON, THE CONSTITUTIONS OF, were certain declaratory ordinances agreed to at a general council of the nobility and prelates assembled by Henry II. at his palace or manor of Clarendon, in Wiltshire, in the year 1164. These ordinances were sixteen in number, and were intended to define the limits between civil and ecclesiastical jurisdictions, to prevent the further encroachments of the clergy, and to abolish the abuses which had arisen from the gradual and increasing usurpations of the pope. (Howell's *State Trials*, vol. ii., p. 546.)

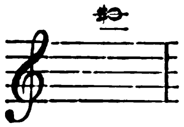
CLARET, a name used in England to denote the red wine of Medoc, or, more correctly, a mixture of that wine and some other description, generally either the wine of Benecarlo, in Spain, or some full-bodied wine, the growth of the southern departments of France, in order to suit the taste of English consumers. The word *clairet*, from which the name is derived, is used in France to signify those wines which are red or rose-coloured, and the name, as understood by us, is not known in that country.

CLARIFICATION, the process of rendering a fluid clear by separating the substances which, being suspended in it, render it turbid. A distinction has been made between filtration and clarification, on the ground that filtration is a mere mechanical operation, while clarification is dependent upon chemical action. In most cases however clarification hardly sustains this character. In clarifying, or, as it is termed, fining, beer, a solution of isinglass or gelatine in stale beer is employed, which carries down the matters that render the beer turbid. Bullocks' blood is used as a clarifier, but more formerly than at present: when mixed with syrup, as the solution of sugar is called, it is coagulated, and carries the impurities along with it; and when they rise to the surface of the fluid they are skimmed off together. White of eggs is also a powerful coagulating clarifier. Sand or clay will in some cases mechanically carry down the impurities of liquors, and render them clear.

CLARINET, a musical instrument made of wood, similar in shape to the oboe, but of rather larger dimensions, and having a fixed mouth-piece containing a reed, which forms the upper joint of the instrument. It was invented at the commencement of the last century by Denner of Nuremberg, though it has not been in general use more than fifty years. The clarinet gives all the sounds of the diatonico-chromatic scale, but the same instrument cannot be used in all the modes, or keys; hence in the orchestra three instruments are employed, of different dimensions, namely, a C, a B, and an A clarinet: that of B is preferred by performers, because more mellow in tone, and more manageable as regards fingering. The compass of the clarinet is from E, the third space in the base, to G in altissimo.



But in the orchestra it is seldom required to go higher than C♯ in alt.



The sounds between the lowest note (E) and B♭, the third treble line, are called *Chalumeau* notes, or notes resembling an antient rustic instrument so named, which was formed of reed.

BASE CLARINET. This was invented, in 1828, by Streitwolf, an instrument-maker of Göttingen. It is made of wood, and played on in the same manner as the common clarinet. Its compass is four octaves, and it descends to B♭ below the base staff. In length it is two feet eight inches.

CONTRA-BASE CLARINET. The same ingenious artist subsequently produced a *double-base* clarinet, which stands in the same relation to wind instruments of wood that the *contra-basso* (double-base) does to stringed instruments, and promises to become very useful in the orchestra. Its form and manner of fingering differ but little from those of the base clarinet: in size it is not larger than the bassoon, and in compass is four notes lower.

CLARION, a kind of trumpet, very shrill, and not now in use.

CLARKE, DR. SAMUEL, was born in October, 1675, at Norwich, where, at the free school, he was distinguished for his progress in classical studies. He entered, in 1691, at Caius College, Cambridge, and applied with great success to the mathematics, under an able tutor, Mr., afterwards Sir John Ellis. The text-book then used in the university was a rugged Latin version of the treatise of Rohault, an implicit follower of the Cartesian theory. Clarke, at the age of 21, after closely studying and justly appreciating the reasonings of Newton's 'Principia,' which had then just appeared, published a more classical version of the text of Rohault, with numerous critical notes, added with the view of bringing the Cartesian system into disrepute by exposing its fallacies. After passing through four editions as the university text-book, it gave place, as Clarke desired, to the adoption of undisguised Newtonian treatises. He now went through a diligent course of biblical reading, in the original languages, in the course of which he carefully studied the early Christian fathers. On his ordination he was introduced to Dr. More, bishop of Norwich, by Whiston, whom he succeeded as domestic chaplain to that bishop for twelve years. In 1699 he published three essays on Confirmation, Baptism, and Repentance, together with Reflections on Toland's 'Amyntor,' concerning the uncanonical Gospels

Two years afterwards followed his 'Paraphrase of the Four Gospels,' which induced Bishop More to present him with the living of Drayton, near Norwich. In 1704 he was appointed to preach the Boylean lecture at Oxford, when he chose for his subject 'The Being and Attributes of God.' The satisfaction which he gave on this occasion led to his re-election the following year, when he read a series of lectures on the evidences of natural and revealed religion. These discourses were arranged and published as a continuous argument, and passed through several editions with successive improvements. Clarke's mode of demonstrating the existence of God by a process of reasoning from an *à priori axiom*, is precisely that of Spinoza, against whom the argument of Clarke is especially directed. Both take the same point of departure, and agree that, since something does exist, something always has existed. They assert that eternity and immensity, time and space, or duration and extent (for each of these pairs of terms is used without distinction), have always existed, the conception of their non-existence being impossible. It is then considered that, as these are only attributes or qualities, they must necessarily imply a co-existent substance whose attributes they are: a necessary and eternal Being is therefore acknowledged by both, but as to the nature of this Being they differ entirely. Spinoza, like some of the Greek philosophers, concludes this eternal and necessary substance to be the universe itself, material and mental (*τὸ πᾶν*), which he declares to be the great and only God in whom we live, and move, and have our being. (Compare the passage of Pope's 'Essay,' 'All are but parts of one stupendous whole,' &c.) Clarke asserts that this substance, of which duration and extent are the attributes, is an immaterial and spiritual Being: this metaphysical notion is evidently derived from a passage in a scholium of Newton's 'Principia,' where it is said, 'Durat (Deus) semper et adest ubique; et, existendo semper et ubique, *durationem et spatium constituit*,' &c., a notion very different from that of Bishop Watson, who speaks of God as having no relation to space or time (*Apol.*, p. 135). Spinoza takes no notice of design as evidence of intelligence; and Clarke, in assigning to his personification of eternity and immensity certain moral attributes in accordance with his metaphysical hypothesis, admits that intelligence, in which lies all the difference between the Theists and Atheists, cannot be demonstrated by any reasoning *à priori*, but must depend for proof on the *à posteriori* evidence from observation and induction (prop. 8). According to his premises, he cannot, by logical sequence, avoid landing himself on the same ground with Spinoza. 'It must be owned,' says Sir James Mackintosh (*Dissert. Ency. Brit.*), 'that he is compelled to assume what the laws of reasoning required him to prove,' that is, the existence of a Being extraneous to the constituent parts of the universe. (See *Edinburgh Review*, vol. lii., p. 113, 114). Numerous replies and objections to this *à priori* argument appeared at the time of its first publication. (See a list in Kippis's *Biog. Brit.*, and the correspondence between Butler, afterwards bishop of Durham, and Clarke, printed at the end of Bishop Butler's Works.) One of the principal was 'An Inquiry into the Ideas of Space, Time,' &c., by Bishop Law. The most subtle scholastics, Albert, Aquinas, and Scotus, rejected the *à priori* proof as an obvious *petitio principii*, and many modern writers regard the performance of Clarke as a failure. Pope, who on several occasions says sarcastic things of Clarke, alludes to it in the following passage of the 'Dunciad,' b. iv., l. 455:—

> We nobly take the high priori road,
> And reason downward till we doubt of God.'

The 'Evidences' met with equal opposition. The foundation of morality, according to Clarke, consists in the immutable differences, relations, and eternal fitness of things. The last expression being of frequent occurrence in this discourse acquired a fashionable usage in the ethical vocabularies of the day. Regardless of moral sentiment, so fully developed since by Shaftesbury, Hutcheson, and Adam Smith, Clarke insists solely upon the principle that the criterion of moral rectitude is in the conformity to, or deviation from, the natural and eternal fitness of things: in other words, that an immoral act is an irrational act, that is, an act in violation of the actual ratios of existent things. The endeavour to reduce moral philosophy to mathematical certainty was characteristic of that age, and led to the formation of theories remarkable more for their ingenuity than utility. Dr. Price is an apologist for the moral theory of Clarke, and among its oppugners we may instance Sir James Mackintosh. (*Dissertat. Encyc. Brit.*)

In 1706 Clarke obtained, through Bishop More, the rectory of St. Bennett's in London. He published in the same year an answer to the treatise of Dr. Dodwell 'On the Soul,' in which that divine contends that it is not immortal until made so by baptism. Several rejoinders followed on each side. (See Kippis, *Biog. Brit.*) [COLLINS, ANTHONY.] Clarke at this time published a Latin translation of the treatise 'On Optics,' by his friend Sir Isaac Newton, who in acknowledgment presented him with 500*l.* for his five children. His patron, Dr. More, next procured for him the rectorship of St. James's, and a chaplaincy to Queen Anne, which induced him to take his degree of D.D.; and it is said that no such logical conflict was ever heard in the schools of Cambridge as that which occurred on this occasion between Clarke and Professor James, who, in concluding, exclaimed, 'Profectò me probe exercuisti!' The theses sustained by Clarke were, that 'no scriptural article of Christianity is contrary to reason,' and that 'free agency is indispensably essential to all moral and religious conduct.' In 1712 he published his edition of Cæsar's 'Commentaries,' in folio, with notes, and some fine engravings. The same year appeared his treatise on 'The Scripture Doctrine of the Trinity;' a work which involved him for the remainder of his life in a controversy, in which his principal adversary was Dr. Waterland. The Lower House of Convocation, in 1714, complained to the bishops of the heterodox and dangerous tendency of its Arian tenets, and Clarke was prevailed upon to declare that he was sorry for his offence, and hoped that his future conduct would occasion no further cause of complaint; an act for which he was sternly reproached by his more courageous friend Whiston. A circumstantial account of this proceeding is given in the 'Apology for Dr. Clarke,' 1714. His favourite subject was the doctrine of philosophical liberty and necessity; on which he began, in 1715, to carry on an amicable controversy with Leibnitz. The papers written on each side were printed, in 1717, in English and French, and dedicated to Queen Caroline, who is said to have carefully examined each MS. previous to publication. In advocating the doctrine of free will, Dr. Clarke had constantly in view the subversion of the writings of Spinoza, which contain, says Dr. Reid, in his 'Essays,' 'the genuine and most tenable system of necessity.' The death of Leibnitz left the controversy undecided, and Clarke soon afterwards resumed his argument in reply to the 'Philosophical Inquiry concerning Liberty,' by the friend of Locke, Anthony Collins. Dugald Stewart, having himself adopted the anti-necessarian doctrine, insists upon Clarke's having gained a great victory over Leibnitz and Collins, and that his arguments on this subject are the most important and powerful of all his metaphysical writings; but many competent judges are of a different opinion.

In 1718 he occasioned a zealous controversy about the primitive doxologies. Dr. Robinson, bishop of London, put forth a pastoral letter, in which he strictly prohibited his clergy from adopting the Arian modifications of Dr. Clarke charging them, as they hoped to obtain God's mercy, to hold them in great abhorrence, as emanating from a strong delusion of pride and self-conceit. Several pamphlets by Whiston and others appeared on this occasion. In 1724 Clarke obtained the mastership of Wigston Hospital, and published a volume of seventeen sermons. On the death of Newton he declined the offer of the mastership of the Mint. At this time he published in the 'Philosophical Transactions' (401) a paper on the velocity and force of bodies in motion. In 1729 appeared his edition of Homer, with Latin version and notes, which is still used in schools. The last nine books were not prepared by Dr. Clarke. He died rather suddenly in May, 1729. His 'Exposition of the Church Catechism,' and ten volumes of sermons, were published after his death. That he retained to the last his Unitarian views, is proved by his emendations of the Liturgy shortly before his death —the MS. of which is in the British Museum—and by the statements of his friend and biographer Bishop Hoadley The moral character of Clarke is admired by all his biographers: his temper was remarkably mild, and his manners modest and unassuming. As a writer he is plain and unaffected; very accurate, but monotonous, tame, and jejune. Voltaire, not without propriety, calls him a *moulin à raisonnement*. He was a wary and very skilful disputant, well disciplined in the scholastic logic. Inferior to

Locke in comprehensiveness and originality, he was greatly superior to him in acquirements, being eminent as a divine, a mathematician, a metaphysician, and a philologist. Dr. Hare, in his 'Difficulties and Discouragements in Studying the Scriptures,' says that Clarke possessed every possible good quality.

(Kippis's *Biog. Brit.*; *Life* by Bishop Hoadley; *Historical Memoirs* by Whiston; *Dissertations* by D. Stewart and Mackintosh, in *Ency. Brit.*)

CLARKE, EDWARD DANIEL, LL.D., &c., was descended from a literary family, and born at Willingdon, in Sussex, on the 5th of June, 1769. He received part of his early education in the grammar-school of Tunbridge, at that time conducted by Dr. Vicesimus Knox. At this early age he showed a fondness for experimental philosophy and physics, but was otherwise an indolent student. In 1786 he went to Jesus College, Cambridge, where, as the orphan of a poor clergyman, he was for some time in very straitened circumstances. Having taken his degree he was engaged by the duke of Dorset, in 1790, as tutor to his nephew, Mr. H. Tufton, with whom, in the course of the following year, he made the tour of Great Britain. Clarke had always been fond of books of travel, and this journey confirmed his passion, and led to his first essay in travel-writing. He published his journal, but without his name, and was very soon ashamed of it. The edition, which was in 2 vols., 8vo., with plates in aquatinta, is now extremely scarce. In 1791 he made a trip to Calais, and seems to have been delighted beyond measure at putting his feet on foreign land. In the course of the following year he engaged as a travelling companion to Lord Berwick, with whom he went through France, Switzerland, and Italy. He returned to England at the end of 1793. In the course of the following year he went again to Italy by the Rhine and the Tyrol, and returning again to England he was chosen fellow-elect of his college, a barren honour without any emolument. For want of a better occupation, he for some time thought seriously of joining the Shropshire militia, in which he was offered a lieutenancy; but in September, 1794, he became tutor in a distinguished Welsh family (that of Sir Thomas Mostyn), with whom he resided some time in Wales, where he made the improving acquaintance of Mr. Pennant. He was afterwards connected in the same manner with the family of Lord Uxbridge, with a member of which he made the tour of Scotland and the Western Isles in 1797. In all these excursions he kept journals, and practised himself in the art of observing scenes and objects, and describing them. About this time he was elected fellow of his college, and being, in addition, appointed bursar, he took up his residence at Cambridge at Easter, 1798. In the spring of the following year he set out with Mr. Cripps, a young man of fortune, on a tour to the countries north of the Baltic. This journey, which was at first intended to occupy only six months, was continued through more than three years and a half, during which master and pupil traversed Denmark, Norway, Sweden, Lapland, Finland, Russia, Tartary, Circassia, Asia Minor, Syria, Palestine, part of Egypt, Greece, Turkey in Europe, and finally returned from Constantinople, across the Balkan mountains, through Germany, France, &c., to England. In consequence of their donations to the University of Cambridge, and other merits, Clarke received the degree of LL.D., and Cripps that of M.A. Among their valuable donations was a fragment of a colossal statue of the Eleusinian Ceres, of the best period of Grecian art. Clarke was also the means of securing for his country the antient sarcophagus, generally but incorrectly called that of Alexander the Great, now in the British Museum. He made considerable collections of medals, minerals, and rare plants: many of the latter he procured from Professor Pallas, in the Crimea. The valuable collection of MSS. which he had made during his travels, he sold to the Bodleian Library, Oxford. In 1807 he began, at Cambridge, a course of lectures on mineralogy, which had become his favourite subject; and at the end of the following year the University established a regular professorship of mineralogy in his favour. Having been ordained in 1805, he received the college living of Harlton, and about four years later he obtained the living of Yeldham from Sir William Rush, whose daughter he had married in 1806. From this time his life was almost entirely passed at Cambridge or in its immediate neighbourhood. In 1810 he published the first volume of his Travels; the second volume appeared in 1812, the third in 1814, the fourth in 1816, and the fifth in 1819. A concluding volume, edited by Robert Walpole, was brought out after his death, making the sixth volume, 4to. His Travels, by which he is chiefly known, are the most popular of his works, and are written in a style which invariably captivates the reader. Full of enthusiasm, and gifted with a prolific imagination, he throws a charm over all that he describes; but unfortunately, his judgment was not sufficiently formed by proper discipline, and neither his observations nor his conclusions can always be relied on. His essays and experiments in physics chiefly appeared in Thomson's 'Annals of Philosophy,' which contain his accounts of the blowpipe, cadmium, &c. In 1803 he published 'Testimonies of different authors respecting the colossal Statue of Ceres;' and in 1805 'a Dissertation on the Sarcophagus in the British Museum.'

He died at Pall Mall, London, on the 9th of March, 1822, and was buried in Jesus College Chapel on the 18th of the same month. (*Life and Remains of Ed. Dan. Clarke*, by the Rev. William Otter, M.A., two volumes, octavo, London, 1825.)

CLARKE, ADAM, LL.D., a highly respected minister among the Wesleyan Methodists, not long ago deceased, the author of various works held in very general esteem, and in several points of view a somewhat remarkable character.

He was born in or about the year 1762. His parents resided in the North of Ireland. They appear to have been persons of respectable character; and his mother especially, who was a native of Scotland, was herself deeply impressed with a sense of the value of high devotional sentiment in union with religious knowledge, and she acted accordingly in the influences which she sought to communicate to her son.

Of education, properly scholastic or systematic, he appears to have received little or none. The effect of this misfortune of his early years is perceived in almost all his writings, as well as in the general tone and character of his mind. The want of it gave a character, and that not a favourable one, to the learning which it is admitted by all that he did by his own unwearied exertions afterwards acquire.

As soon as his mind began to develop its peculiarities, it appeared that Dr. Clarke was extremely eager after knowledge, and possessed within himself resources which would enable him to overcome very formidable obstacles. When he was placed with a linen manufacturer, who lived in the neighbourhood of his father, to learn the trade, he soon found that he was in a situation that afforded no means of gratifying his desire of knowledge. He determined to change the mode of life which had been marked out for him, and he returned to his home. He has related of himself a circumstance which is highly characteristic: that at a very early period of life he took from the Hebrew writers, as his favourite motto, the words, 'Through desire a man having separated himself seeketh and intermeddleth with all wisdom.'

Methodism had been introduced into the part of Ireland in which he resided. His father and mother belonged to that society. There was a Mr. Breedon, one of Mr. Wesley's earliest ministers, who was a friend and the religious instructor of the family, to whom at this period of his life he seems to have owed much.

The union of considerable natural powers with no mean attainments, considering the great disadvantages under which he lay, and of the love of study with a mind eminently devotional, pointed out this young man to the Methodist preachers who frequented his father's house as a person who might be useful in the ministry among the people with whom his family had formed their religious connexion. One of them was so impressed with the persuasion that this was the course of life pointed out for him, that he communicated the circumstance to the great father and director of Methodism. The result was that Clarke removed to England, and was admitted into the school which Wesley had founded at Kingswood near Bristol.

He now found himself in circumstances more favourable for the gratification of his desire to acquire varied knowledge. Not that much was to be learned in such a school as that; but his new situation gave him *time*, which is what a mind disposed as his was chiefly wants. Besides what formed the kind of instruction which was imparted to the students in this school, he undertook to teach himself other things: and it was while here that he purchased a Hebrew Grammar and began the study of that language, which was the commencement of that course of oriental study in which he afterwards spent much time, and made as is believed, great progress.

The time soon came when he was to leave this school, and enter on the duties of an itinerant or travelling preacher. He was accustomed to relate with pride and pleasure that he received his commission to go forth from the mouth of Mr. Wesley himself. There was a peculiar and touching affectionateness in the old man's benediction. The circuit, as it is called, to which he was appointed was a tract of country near Bradford in Wiltshire.

Thus, in 1782, he became a Methodist preacher, and so continued to the time of his death. In the first twenty years he resided in various parts of the kingdom, but afterwards he lived, for the most part, in or about London, or at an estate which was purchased for him in Lancashire.

In his ministerial character he was singularly acceptable and useful. His preaching attracted crowds. He advanced in influence and reputation in the body of Christians to whom he belonged: and for many of the latter years of his life he was regarded as one of the chief lights and brightest ornaments of that religious community.

If this however had been his only claim to distinction, the name of Dr. Clarke would not have appeared in this work or in the many writings in which, since his death, mention has been made of him. We have already intimated that he was eminently desirous of knowledge of very various kinds, and, while leading the laborious life of a travelling preacher, he found time for a great variety of discursive reading, as well as for much steady application to his philological studies, especially those of Oriental literature. He first gave public evidence of those studies in the year 1802, when he published, in six volumes, his book entitled 'A Bibliographical Dictionary.' This work gave him at once a literary reputation, and it may fairly be said to do him no small honour; not that we mean to represent it as to be placed on a level with the works of De Bure, Panzer, and Brunet, or that it is the result of original researches like the work of our own Ames and Herbert, but it is a most convenient book for the English student, who found nothing like it in the literature of his own country, and it contains a great body of information well arranged concerning books and authors to which no other easy access was presented. The book had, we believe, an extensive circulation.

A Methodist preacher possessed with a taste for the curious researches of which this book was indicative, was a phenomenon that had not before presented itself. It was regarded, we believe justly, as manifesting that a taste for human learning was beginning to prevail in a class of men whose profession might almost be said to be founded on a contempt for such acquisitions, and of whom at least it might be said that they so exalted other objects and other principles that learning merely human was defeated of its just appreciation. We wish that the biographers of Dr. Clarke had informed us how this work was received by his brethren in the ministry, and especially by his elder brethren. He gained however by it a certain reputation among another class of men, the bibliographical and philological inquirers of his time. He began also about this period of his life to be taken notice of for his acquirements in Biblical knowledge and in Oriental literature. On his coming to reside permanently in London, the Bible Society brought him into connexion with some of the dignitaries of the church. His connexion with the Surrey Institution gave him access to several persons of literary pursuits, and at the same time an easy access to books. He was admitted a Fellow of the Society of Antiquaries. The University of St. Andrew's conferred on him the degree of M.A., and afterwards of LL.D. Some time after he became a member of the Royal Irish Academy.

But the most extraordinary circumstance in his literary history remains to be mentioned. The Board of Commissioners on the Public Records selected Dr. Clarke as a proper person to superintend the publication of the new edition of Rymer's 'Fœdera,' with the preparation of which they were charged.

This was a great and difficult undertaking; for it was not the mere reprinting the work of Rymer, but a large mass of new materials were to be found and to be incorporated with the old. Some eminent antiquarian scholars had shrunk from the task. What particularly pointed out Dr. Clarke as a suitable person for this undertaking is not known, as it was evident that his studies had previously lain in a direction very different from that which pointed to such a work as the 'Fœdera,' and he himself acknowledged that he came to the task with very little acquaintance with the nature of it. He however laboured at it with much assiduity for several years. His name appears in the title of both parts of the first volume, and in the first part of the second volume, which was published in 1818, and from that time Dr. Clarke relinquished his share in the undertaking.

From the time when he settled in London he was constantly in communication with the press. Of some works he was only the editor; others he abridged: and he prepared some original works, among which are particularly to be named, 'A Supplement to his Bibliographical Dictionary,' 'Memoirs of the Family of Wesley,' and a work for the assistance of Biblical students. He was also a frequent contributor to the periodical literature of his day. His, as much perhaps as ever any man's, was at this period a life of incessant literary exertion. His health was good.

But there was one great literary undertaking on which, above all, his mind was intent. This was an edition of the 'Holy Scriptures' in the English version, illustrated with a commentary and critical notes, into which he proposed to throw the results of his own Biblical studies, together with much that he might collect from preceding commentaries. It was to form a kind of Family Bible, and yet be at the same time a book which the Biblical scholar might consult with advantage,—a union which has been several times attempted. The first volume appeared in 1810, and excited no small attention on account of the novelty of some opinions expressed in it respecting the tempter of our first parents. From this period he pursued this work as the main business of his life, till he had completed it, which he did in 1826, when appeared the eighth and last volume. For eight of these years, namely from 1815 to 1823, he lived at a place called Millbrook in Lancashire, where some friends had purchased for him a house and small estate.

We have not attempted to give an estimate of the literary value of Dr. Clarke's publications, or even to enumerate them all. We may observe however that they appear to us to have had their full meed of fame. Dr. Clarke, like other extraordinary men who have appeared in situations in which the world did not expect to find them, has perhaps been overrated. It is also of the nature of religious sects to force up into undue elevation persons really meritorious who belong to them. It is quite absurd to place his scholarship on a level with that of the really great scholars who have adorned our country; and it is perhaps one of the most observable circumstances about Dr. Clarke that his mind never seems to have acquired that refinement which scholarship, when it is genuine, never fails to give, or that superiority to vulgar prejudices and to the affectation of display which is, we believe, the usual accompaniment of high attainments. There is in Dr. Clarke a remarkable affectation of bringing forward the Oriental learning he is understood to have possessed. He cannot keep it out of the introduction to the 'Fœdera.' It appears still more strangely in his 'Lives of the Wesley Family,' where he labours after an Arabic etymon of the surname of Wesley, a word really formed according to one of the commonest analogies of our own language. In the same work he gives encouragement to the most vulgar and childish of the popular superstitions. But while we make these remarks, we wish it to be understood that we regard Dr. Clarke as a person on whom it is impossible to look but with respect, and whose life presents an instructive lesson of rewards and honours attending useful labours and consistent virtuous action. We may add also that it shows how the cultivation and encouragement of the devotional spirit may be united with very vigorous exertion in things which have but a slight connexion with it. We must not omit to add two or three circumstances of his later years.

While he resided in Lancashire the two Buddhist priests, whom Sir Alexander Johnston brought from Ceylon for instruction in Christianity, were placed in his family; he was the means of establishing a Methodist mission in the Shetland Islands; and in 1831, a little before his death, he had the satisfaction of establishing schools in the province of Ulster, the part of Ireland in which he was born. He accumulated a good library, including many manuscripts, and had formed a small museum of natural curiosities.

From 1823, when he left Lancashire, Dr. Clarke resided at Haydon-Hall, in Middlesex, about seventeen miles from London. He died of cholera on the 26th of August, 1832, the only person of much celebrity who was carried off in that time of the nation's visitation.

CLAUDE. Claude Gellée, called Claude Lorraine, was born at Chamagne, in Lorraine, in 1600. His parents were very poor, and it is said that he was originally bound apprentice to a pastrycook. At the age of twelve, being left an orphan, he sought a home at the house of his elder brother, who was in business, as a carver of wood, at Friburg. A relation, who was a travelling dealer, observing some indications of a love for the fine arts, persuaded his brother to allow the lad to accompany him to Rome. Here he was somewhat unceremoniously deserted by his relative, but received pecuniary assistance from his brother. Seeing some paintings by Godfrey Waals which pleased him, he determined to go to Naples, where that painter then resided, to obtain the benefit of his instruction. At the expiration of two years he returned to Rome, attracted by the fame of Agostino Tassi, under whom he studied with unwearied diligence. Having acquired some repute, he made the tour of Italy and France, and part of Germany, staying occasionally for some time at different places to replenish his purse, and paying a visit to his native place. He appears to have frequently suffered through various misadventures, both in health and fortune, during his protracted tour.

On his return to Rome he was received with a general welcome, and a wide and increasing demand for his pictures. Commissions came to him from numerous places, and from many illustrious persons of the principal countries of Europe. He died in 1682.
